A preliminary clinical survey was made in each case, including a complete neurologic examination in which an attempt was made to record the degree of severity of each manifestation of the disease as accurately as possible. Strength of grip was tested with the dynamometer. Each patient who was able to cooperate was given a sheet of paper on which he wrote his name, a short sentence and a series of numbers and copied a few conventional figures; namely, a square, a triangle and the like. In addition, motion pictures of ten ambulatory patients were taken.

During the course of the treatment with benzedrine sulfate, our patients reported weekly on their subjective symptoms, observations as to any change in their physical status were noted and frequent determinations of the blood pressure were made. At the end of the experimental period, in addition to a physical check-up, the subjects were asked to repeat the writing and copying tests, the strength of grip was again tested, and motion pictures were taken of the same patients.

Two doses of benzedrine sulfate were given daily, the first at 8 a. m. and the second at noon. The age and systolic pressure of the patient were used as determining factors in prescribing the initial dose. Young people with systolic pressures of 130 mm. of mercury or under were given doses of 60 mg. daily, 30 at 8 a. m. and 30 at noon. Those persons with systolic pressures over 130 mm. of mercury, and a few people of advanced years, were given only 40 mg. a day, and this dosage was maintained throughout the experiment. Fifty-eight patients were given 60 mg. of benzedrine sulfate a day, while sixteen were given 40 mg. a day.

Since it is practically impossible to withdraw classic medication such as scopolamine and stramonium from the patient with chronic encephalitis once he has become accustomed to these drugs, it was thought advisable to continue any medication that the patient was receiving at the time of the preliminary examination and to consider the signs and symptoms that were elicited while the patient was taking his usual dose as normal for his condition. We therefore did not alter the previous regimen of the patient but merely prescribed the suitable dose of benzedrine sulfate and observed what changes were produced by the administration of benzedrine sulfate. Although prompted by necessity, we felt that there was some justification for this technic, as it might give

us some data on the synergic effect of benzedrine sulfate with the atropine group in this disease.

Twenty-nine of our patients were taking no drugs at all before the study was begun. Of the forty-five who were accustomed to medication, thirty were taking stramonium, ten were taking scopolamine and two were taking atropine. Three were taking both atropine and scopolamine. The dose of these drugs was at no time increased during the course of the study.

As others have observed, the most remarkable and uniform effect of benzedrine sulfate in postencephalitic parkinsonism is in the subjective sphere. All but eight patients felt definitely improved. The majority reported a decrease of fatigability and somnolence with a definite increase in energy and mental alertness associated with a sense of well being. Many were able to resume responsibilities that they had been incapable of for months and years. Several practically helpless patients started feeding themselves with a moderate amount of success, and one woman who had been bedridden for almost two years was able to get out of bed and helped to dress herself.

However, evaluating our results, we placed much more weight on objective evidence than on subjective evidence of the action of this drug. Most physicians have witnessed at some time or another the effect of a strong emotion on the postencephalitic patient and have been amazed at the extent to which the otherwise board-like extremities can be driven into activity. These spurts of activity, emotionally driven, are of course of very short duration, but even so they are striking enough to make one demand something more concrete when one is evaluating results with any form of treatment.

Therefore, while sixty-six of our patients reaped definite subjective benefit from the use of benzedrine, from the objective standpoint we were satisfied with the improvement of only fifty-three of the cases. The most striking result was the effect on the oculogyric crises. Only twenty-three of the patients showed this symptom, and in every case the attacks were reduced

TABLE 2.—*Fifty-Eight Cases with Blood Pressure Less than 130 Mm. of Mercury*

	Number of Cases
Blood pressure decreased	11
Blood pressure increased	41
Blood pressure unaffected	4
Blood pressure vasculating	2

Benzedrine Sulfate is the trade mark for the Smith, Kline & French Laboratories brand of benzyl methyl carbinamine sulfate. The manufacturers supplied the benzedrine sulfate for this study.

either in frequency or in duration. However, in no cases were they completely relieved. There was a very marked increase in the strength of the grip in fifty-three of the patients, in some to the extent of four or five fold.

There was a marked improvement in the ability to write and to draw on the part of forty-eight of the sixty-three patients who were able to write before treatment, and of the eleven who were not able to copy even the square on the first trial there were three who were able to copy several of the figures while taking the drug.

This improvement in writing and drawing is probably due to a general improvement in the extrapyramidal complex of symptoms and is a more accurate index of

the degree of tremor, rigidity and loss of habit movements than the usual methods of estimating them.

Tremor was noted in sixty-six cases and rigidity in seventy-two. Tremor was reduced in nineteen cases, unaffected in forty and augmented in seven. Rigidity was decreased in twenty cases, unaffected in forty-six and increased in six. The ability to perform serial movements was increased in twenty-four of the cases, unaltered in forty and diminished in ten. As we have already pointed out, the writing test probably gives a more accurate index of these abilities than the mere clinical observation of the examiner.

The effect of benzedrine sulfate on the blood pressure in this series gave us some interesting data. The blood pressures were increased in forty-four, decreased in twenty-one, unaffected in seven and variably affected in two cases.

In the sixteen cases showing systolic blood pressures of over 130 mm. of mercury, the pressures were decreased in ten, unaltered in three and increased in three (table 1).

In the fifty-eight cases showing systolic blood pressures of less than 130 mm. of mercury, the pressures were decreased in eleven, unaffected in four, increased in forty-one and of a vasculating type in two (table 2).

Benzedrine sulfate has vasopressor potentialities. In the majority of our patients with low blood pressure the drug increased the tension from a moderate to a marked degree, whereas in the majority of our patients under high tension the drug decreased the blood pressure below the previously recorded level. The latter effect of the drug, which is a vasopressor, seems paradoxical.

The synergic effect of benzedrine with the atropine group was nicely brought out by the fact that 82 per cent of the patients receiving constant doses of these drugs showed improvement while only 64 per cent of the patients receiving benzedrine alone presented sufficient objective evidence of benefit to be classed as improved. The synergic effect of benzedrine with the atropine group has been pointed out by Myerson, Loman and Dameshek.²

The untoward effects of benzedrine sulfate on our patients as judged by the results of large doses are insignificant. Three patients complained of excessive sweating. One very restless patient with parkinsonism complained that it increased her restlessness to an almost unbearable degree. It produced insomnia only in those who failed to follow instructions and took the drug late in the afternoon.

COMMENT

While the results here reported are not as favorable as those coming from other hospitals, we feel that the discrepancy is due to the severity of the conditions dealt with rather than to differences in methods of observation. Practically every case in our series is of long standing and fairly far advanced. All but one of our patients are too handicapped to be self supporting, and thirty-eight are confined to the wards. We therefore feel that an improvement in 71.6 per cent of our patients indicates the usefulness of benzedrine sulfate in the treatment of this disease, and while it may not produce the striking relief of symptoms that is seen with the atropine group, it has this advantage: that a constant dose seems to be adequate and the patient does not become a slave to it, requiring larger and larger doses,

as is the case with stramonium and scopolamine, nor has it the distressing side effects frequently seen with the belladonna group.

CONCLUSIONS

In the postencephalitic Parkinson syndrome, benzedrine sulfate, combined with the belladonna group of drugs or alone, is a very useful medication.

FRACTURE OF THE ATLAS IN AUTOMOBILE ACCIDENTS

THE VALUE OF X-RAY VIEWS FOR ITS DIAGNOSIS

H. F. PLAUT, M.D.

CINCINNATI

THE JOURNAL has frequently discussed the causes and effects of automobile accidents and has published instructive papers on the typical injuries happening to automobile riders, such as crushing of the facial bones with loss of front teeth, and cuts. The present report draws attention to fractures of the atlas caused by automobile accidents. They are less conspicuous lesions than the ones just mentioned.¹ Still, proper diagnosis and treatment would prevent unpleasant sequelae and are necessary for medicolegal reasons.

The conception of "broken neck" is frequently associated in the minds of laymen and physicians with cord injuries and a high mortality. This is true for some of the occupational accidents, as in miners. Fracture of the atlas, however, is far less hazardous, as will be explained. During the last century, fractures of the first cervical vertebra were hardly discovered without autopsy. Since then the x-rays have made it possible to diagnose this injury during life.

Only ninety-three cases of fractures of the atlas were found in the entire literature. Six such injuries occurring in the last few years were among the material available to me. This indicates that such fractures are not so rare as was formerly assumed.

The first cervical vertebra is well guarded by the skull, mandible and surrounding soft parts. It is formed by the two substantial lateral masses connected by the anterior and the somewhat thinner posterior arch. Instead of a spinous process there is only a posterior tubercle. The transverse processes extend far laterally and are traversed by the vertebral artery and vein. The artery turns medially before entering the foramen magnum and follows the upper surface of the posterior arch in a groove. The atlas has no body proper; instead, the odontoid process of the axis (epistropheus) extends into the anterior part of the atlas ring. The position of this pivot for the rotation of the skull and the atlas is secured by the strong transverse ligament. The wide vertebral foramen offers ample space for the medulla.

The atlas is extremely seldom injured by direct violence except by projectiles. Its singular shape and function prevent the application of our usual conception of the pathology of spinal fractures. X-ray examination and autopsy reveal a few very typical sites for fractures of the atlas: the bilateral and unilateral ones in the posterior arch, where it is weakened by the groove for the artery, and those in the anterior arch. Breaks of the transverse processes and in the lateral masses are the exception.

1. Dyas, F. G., and Goren, M. L.: Bumper and Fender Fractures. *Surge., Gynec. & Obst.* 65: 690-694 (Nov.) 1937. Strath, C. L.: Automobile Injuries. *J. A. M. A.* 109: 940-945 (Sept. 18) 1937.

Former reports from rural districts and gymnasiums explain very well the mechanism in fractures of the atlas. Either the injured person has fallen headlong onto soft ground or onto a quilt or similar material, or an object such as a sack of starch has dropped on his head. The well defined posture of the gymnasts and in many more instances the lacerations of the scalp give some clue to the forces acting on the body. A violent blow to the head with a hard implement would probably cause a skull fracture. A more gradual pressure on the relaxed neck would result in the common fracture of the fifth and

Fig. 1.—Half-schematic diagram of a bilateral fracture of the posterior arch of the atlas. The short arrow points to the fracture gap; the longer arrow indicates the dislocation.

sixth cervical vertebrae, where the curve of the spine turns from a lordosis into the normal dorsal kyphosis.

However, pressure brought on the neck by more resilient material while the neck is fixed in the straight position is met by counter pressure from the remaining spine. Squeezed between the forces, the wedgelike lateral masses are displaced laterally, bursting the atlas ring at its weak points in the posterior or anterior arch. In forced backward flexion of the skull with the cervical spine, the spinous process of the axis and the occiput may act on the posterior circumference of the atlas as on a lever. A case of ours seemed to indicate that the atlas was pushed upward beyond the limits of its flexibility, suffering a bilateral fracture of the posterior arch. Occasionally pressure of the odontoid process against the anterior arch may lead to a fracture.

Automobile riders, bumping their heads against the windshield or the roof in head-on collisions and in overturning cars, suffer all kinds of spinal injuries, depending on the direction of the force and the position of the neck. Fractures of the odontoid and of the bodies of the fourth and sixth cervical vertebrae and forward dislocations of the third, fourth and fifth cervical vertebrae are reported.² Fractures of the odontoid probably are the result of a push in a more or less sagittal and horizontal direction; incomplete bony union at the base of the odontoid, with a cartilage island remaining in 23.5 per cent of all patients between 30 and 50, may contribute to its occurrence. The reported fractures and forward dislocations of the lower cervical vertebrae probably are the results of such forces as flexion and the momentum of the skull in a sudden stop of the car.

There is no apparent reason why the mechanism of fractures of the atlas in automobile accidents should differ from those in gymnasiums. Vertical pressure

on the skull, with the cervical spine fixed in a straight position, makes the atlas suffer the brunt and yield, when the lateral masses are squeezed between the occipital condyles and the axis.

The chief complaints of patients with atlas fracture are pains in the upper part of the neck, mainly in the nuchal groove, with rigidity and impairment of nodding more than rotation. The painful pull on the fragments by the various muscles participating in the movements of the head and neck quite frequently causes patients to hold their heads with both hands. In fractures of the anterior arch the ensuing hemorrhage into the prevertebral tissues may cause pain and difficulty in swallowing, even in the absence of injuries to the cord. In these cases palpation of the posterior pharyngeal wall is painful although not as informative as, for instance, in dislocations of the atlas. All in all, the clinical signs focus our attention on the upper cervical region. They will not, however, suffice to determine the exact nature of the injury. For a conclusive diagnosis one has to resort to the x-ray examination.

Typical roentgenograms should be taken first. If they do not answer the purpose, films in special or atypical directions should be added. The lateral view of the sitting patient at a distance of 6 feet gives good information about the condition of the cervical vertebrae and their relation to one another. Otherwise the patient can be placed on the table in the lateral position, the cassette being supported by a block with the x-ray tube above. The prone position with turning of the head laterally should be avoided, because the resulting rotation of the upper cervical vertebrae sometimes induces a wrong diagnosis. Unconscious or severely injured patients are examined in the supine position with the cassette placed to the side of the neck, the x-ray tube pointing horizontally. This saves handling of the fractured part. The anteroposterior view is taken through the open mouth, when possible.

Fig. 2.—Diagram of a fracture on the right side of the anterior arch of the atlas. Arrows as in figure 1.

Most of the fracture gaps of the posterior arch are situated close to the lateral masses and are recognized without difficulty in the lateral view. Congenital gap formations, seen in more than 3 per cent of all cases, in contradistinction are smoothly outlined and usually close to the midline.³ In bilateral separation the posterior arch frequently is angulated upward by traction of the rectus capitis posterior minor muscles (fig. 1).

Breaks of the anterior arch often present diagnostic difficulties. In the anteroposterior view this

2. Roberts, S. M.: Fractures and Dislocations of the Cervical Spine, *J. Bone & Joint Surg.* 19: 199-214 (Jan.), 477-495 (April) 1937.

3. Plaut, H. F.: Fracture of the Atlas or Developmental Abnormality? *Radiology* 29: 227-231 (Aug.) 1937.

structure is rather distant from the film, in addition overlapping the odontoid and the posterior arch. Spread of both lateral masses of the atlas laterally beyond the corresponding articular facets of the axis truly proves a separation of the anterior arch (fig. 2). If one lateral mass is in normal articulation with the body of the axis and the other one displaced laterally, this would also indicate a fracture of the anterior arch. In a dislocation of the atlas without fracture the lateral masses would shift for the same distance and in the same direction; the relation of the lateral masses to the odontoid process aids in determining the nature of the lesion.

A good survey of the anterior arch of the atlas is also given by an exposure in nearly axial direction similar to that used for examination of the maxillary sinuses. The central ray should then be directed over the vertex, projecting the atlas in the space between the mandible and the posterior circumference of the occiput. This or axial roentgenograms should not be taken before a fracture of the odontoid or a rupture of the transverse ligament is excluded.

For special demonstration of the anterior arch I have used a new technic: the postero-anterior view of the atlas region on enoral film. A tooth film is pressed against the anesthetized posterior pharyngeal wall (or, if this is impracticable, is placed in vertical position between the molars). The close contact of the film with the anterior arch gives a sharp image of this part and permits studying its details.

The roentgenography of the upper cervical region presents some difficulties which are apt to cause mistakes in the interpretation. No attempt will be made to discuss the differential diagnosis; the interested reader is referred to the more detailed paper.⁴

Associated injuries are skull fractures, dislocations of the atlas and injuries to the remaining cervical vertebrae, especially fractures of the odontoid, each presenting its clinical and radiologic signs. Occipital neuralgias occur frequently and are caused by the fragments of the posterior arch pinching the ganglions.

Injuries to the cord are very rare compared to their incidence in other cervical fractures. The wide aperture of the vertebral foramen of the atlas and the mechanism of its fracture, which favors a lateral displacement of the fragments away from the cord, are responsible. For this reason the mortality in the cases reported since 1900 is as low as 13.8 per cent, in spite of the neighborhood of the vital centers in the medulla oblongata and of the vertebral arteries.

Treatment consists in immobilization to relieve the pain and permit healing. Plaster cast, traction, Thomas collar and, rarely, operation are used. Fractures of the atlas are noted for their lack of callus formation and long lasting pseudarthroses. The majority of the patients regain their full occupational capacity.

FATALITY RATES IN CEREBROSPINAL MENINGITIS

GROESBECK WALSH, M.D.

FAIRFIELD, ALA.

It has been difficult to ascertain the normal fatality rate in epidemic cerebrospinal meningitis before the institution of specific therapy. It is felt that after serum treatment came into use the estimation of fatality rates entered into the controversial field.

Flexner¹ gave the fatality rate in the period from 1904 to 1905 and from 1911 to 1913 as 73 per cent in New York, 69 per cent in Boston, and 76 per cent in Hartford, and listed other cities in this country and Europe with similar or even higher fatality rates. Earlier estimations attempted in the preserum period are as follows:

In addition to the statement of von Ziemssen, quoted by Flexner,¹ that the mortality rate ranged from 35 to 70 per cent, with an average of 40 per cent, Eichhorst, who wrote the chapter on epidemic cerebrospinal meningitis published in Appleton's *Modern Clinical Medicine* in 1905, stated that the disease, as other infectious diseases, showed varying death rates in different epidemics but that in his opinion the fatality rate varied from 20 to 85 per cent.

Chart 1.—Fatality rates at San Francisco.

In Osler's *Principles and Practice of Medicine*, published in 1904, is found the quotation from Hirsch to the effect that the mortality has ranged in various epidemics from 20 to 75 per cent.

Rosenau, in his *Preventive Medicine and Hygiene*, published in 1916, states that in New York for the years 1904 to 1905, the years of the great epidemic, there were 6,755 cases and 3,455 deaths, or a fatality rate slightly in excess of 51 per cent.

In all likelihood thirty years ago the true fatality rate from cerebrospinal meningitis had not been accurately determined, a condition which I believe prevails to a certain extent today. One fact seems to have been recognized by all clinical observers: the wide variability in the fatality rates in different epidemics, a condition which—as will be seen—also exists at the present time.

In order to obtain light on this subject, letters were addressed to a number of the health departments of some of the larger municipalities. It was believed that information obtained from these sources would be valuable for a number of reasons: In the first place it would be compiled without prejudice and in a spirit which disregarded any controversial aspects in the matter; also it would relate to large numbers of people living in close contact with highly developed municipal laboratories where early and accurate diagnosis could

From the Medical Section of the Employees Hospital.

be made and the proper treatment instituted. I believe that there are more cases diagnosed in the cities than in the rural districts, certainly in the earlier years with which this contribution concerns itself.

Through the courtesy of the Office of the Surgeon General I was able to obtain fatality statistics regarding his branch of the military service.

The experience of the personnel of the United States Army, years 1920 to 1936 inclusive, show 359 cases and 125 deaths, or a fatality rate of 34.8 per cent.

The personnel of the United States Army consists of young adults of unusually fine physique, in excellent health in every way, in the prime of life physically, living in the best possible nutritional state with constant skillful medical supervision and daily medical inspection.

When it is remembered that the highest rates in this disease occur at the two extremes of life, among children and among old persons, and when it is remembered also how the general health conditions of the population at large fall far behind those represented in the army, the fatality rate of 34.8 per cent, I believe, is comparable in every way to the fatality rate of 51.2 per cent in the communities under discussion.

Meningitis Data, 1920-1936 Inclusive

The figures referring to the fatality rates in the Chicago area were taken from the article by Dr. Archibald L. Hoyne entitled *Meningitis*, published in the *Journal of the Iowa State Medical Society* 26: 549 (Oct.) 1936.

It is evident from our knowledge of the disease at the present time that a certain number of cases will always escape detection. These cases, I believe, will not only be of the meningococcic septicemia type but also will include some of the milder cases wherein the meninges have been invaded. I have reason to believe, from what I have seen in a recent epidemic, that varying degrees of meningococcic infection take place and that by no means all of them go on to the grave type of the disorder which we have been accustomed to recognize as its only form.

Herrick² estimated that 4 per cent of the cases at Camp Jackson escaped recognition. When one considers that these cases occurred in a body of men under close supervision and at a time when an epidemic was in progress, it is only fair to presume, I think, that the percentage of unrecognized cases in the civilian population, where there was no such supervision and when an epidemic was not in progress, would be considerably higher.

2. Herrick, W. W.: Early Diagnosis and Intravenous Serum Treatment of Epidemic Cerebrospinal Meningitis, *J. A. M. A.* 71: 612-616 (Aug. 23) 1918.

Flexner¹ was aware of this type, to which he referred as "another variety hitherto little remarked, the frequency of which is not known, namely the ambulant, little ill at any time, and recovery is the rule."

Support of this idea is given also by the contribution of Dock.³ He was able to collect sixty-eight cases of meningococcic septicemia, forty-one of which occurred

Chart 2.—Fatality rates at Seattle.

among soldiers. Similar implications, I believe, are reasonable from this contribution.

With these considerations in view I have felt that any standard by which one attempts to estimate fatality rates must be regarded as possessing some degree of elasticity, constructed with frank recognition of the fact that a certain proportion of the cases will always escape notice.

SUMMARY

1. The experience of some twenty million urban dwellers with the disease epidemic cerebrospinal meningitis over a period of sixteen years has been recorded.
2. The fatality rate in different municipalities has varied between 67.7 and 38.1 per cent. The average fatality rate has been 51.2 per cent.
3. I believe that this represents an accurate description of the experience of these communities with this disease for the time specified.
4. It is difficult to estimate the fatality rate of this disease before the use of serum began. The fatality rates recorded by Flexner¹ apparently refer to one or more epidemic outbreaks of the disease.
5. On one point all observers have agreed: the death rate varies greatly from year to year.

Chart 3.—Fatality rates at Milwaukee.

6. Several clinicians of wide experience have expressed the opinion that the fatality rate in the pre-serum era varied between 20 and 80 per cent. Rosenau listed six thousand odd cases occurring in New York State during the years 1904 and 1905 with a fatality rate of 51 plus per cent. The fatality rate defined in this contribution about equals that recorded by Rosenau.

3. Dock, William: Intermittent Fever of Seven Months' Duration Due to Meningococcemia, *J. A. M. A.* 83: 31 (July 5) 1924.

7. It is my opinion from the available evidence that the treatment of epidemic cerebrospinal meningitis as used in the urban population described over the time period to which I have had reference has reduced the fatality rate of this disease little if at all.

8. While there is no factual evidence to support the idea that such treatments in such localities over such time periods have increased the fatality rate of this disease, nevertheless the failure of the fatality rate to decline, as most similar rates in infectious diseases have declined in that period, suggests that the type of treatment referred to may have harmful rather than beneficial effects. This view of the question is of sufficient import to invoke earnest and careful study.

VITAMIN C IN THE BLOOD, SPINAL FLUID AND URINE

HERMAN WORTIS, M.D.

JAMES LIEBMANN, M.D.

AND

ETHEL WORTIS, M.D.

NEW YORK

Vitamin C is found in all body tissues and fluids in varying amounts and is believed to have an important role in all cellular oxidations. In an effort to find a convenient index of the state of vitamin C nutrition, investigators have centered their attention chiefly on the amounts in the urine, blood and spinal fluid. The interpretation of the varying relationships between these and the question of which is the best representative of tissue saturation are still unsettled matters. The method in most general use has been that introduced by Harris and Ray.¹ They determined the proportion of a test dose excreted in the urine within a certain time and found that a large part of it was recovered from well saturated subjects and vice versa. Wright,² Ralli³ and others in this country, using modifications of their technic have preferred this test to determinations of the amount in the blood. Farmer and Abt.⁴ and van Eekelen,⁵ however, have considered the blood level more informative, and Plaut and Bülow⁶ said that determinations on the spinal fluid may supply the best index of vitamin C nutrition.

The present study was undertaken in the hope of correlating these three indexes for a group of patients in differing states of cevitic acid saturation. The five hour urinary excretion test of Wright² was done on 133 patients in the wards of Bellevue Hospital. Just before the test samples of blood and spinal fluid were withdrawn for vitamin C determination. At the same time, capillary resistance tests by both the suction cup and the tourniquet method were made on the majority of these patients; they will be reported in a separate paper.

From the following departments of the Bellevue Hospital: the Department of Pathology, the Laboratory of Experimental Neurology, the Neurologic Division (Dr. Foster Kennedy, director), the First Medical Division (Dr. I. Ogden Woodruff, director), the Psychiatric Division (Dr. Karl M. Bowman, director) and the Second Medical Division (Dr. A. Liggett Lincoln, director).

METHODS AND MATERIALS

The patients tested numbered 133. They were taken in about equal numbers from the general medical and the neuropsychiatric wards. With only two exceptions all patients were afebrile at the time of testing, although a few had recently recovered from febrile illnesses. There was a slightly increased incidence of definite nutritional diseases (six cases of frank scurvy, two of pellagra, three of "malnutrition," eleven of peripheral neuritis of avitaminotic origin and eight of alcoholism without neuritis), because patients with such diseases were referred to us for vitamin studies. Otherwise no attempt was made to select patients on the basis of either disease entities or previous dietary history. It should be noted, however, that the patients at Bellevue Hospital are in general drawn from the lowest income groups and that the majority subsist on diets very low in all vitamins. In addition the routine ward diets are rather low in vitamin C.

On all patients reported in this study a lumbar puncture was done, blood was drawn for vitamin C assay and then 1 Gm. of crystalline cevitic acid,⁷ dissolved in 5 cc. or 10 cc. of sterile distilled water, was injected intravenously. The urine for the next five hours was collected in brown glass bottles and kept acid with sulfuric acid to p_{H_3} . The urine was then titrated (after dilution with distilled water) against Tillman's 2:6 dichlorophenolindophenol.¹ Wright has shown that 80 per cent of the total twenty-four hour excretion following such a test is excreted in the first five hours. He considers as normal any excretion greater than 400 mg. We have accepted this definition of normal in our work.

The blood was oxalated and taken immediately to the laboratory. The centrifugated plasma was titrated by the method of Farmer and Abt.⁴ We considered 0.7 mg. per hundred cubic centimeters as the lowest limit of normal for cevitic acid in blood plasma. This is the figure given for the method by Farmer and Abt, Wright and Greenberg, Rinehart and Phatak.⁸ The levels determined by us for fourteen healthy medical students and interns with adequate diets ranged from 0.74 to 1.38 mg.

The spinal fluid content of vitamin C was also determined by the method of Farmer and Abt. Plaut and Bülow reported losses of as high as 90 per cent of the reducing power of cevitic acid in the spinal fluid after it had stood one and one-half hours at room temperature but stated that it retains three fourths of its reducing power if acidified with 0.1 cc. of trichloroacetic acid to each cubic centimeter of spinal fluid. In our own determinations we found an average loss of reducing power against Tillman's reagent of only 10 per cent in one hour without acidification and only a negligible loss if the spinal fluid was acidified immediately.

Plaut and Bülow have set as normal standards for spinal fluid 1.77 mg. per hundred cubic centimeters for the age group from 20 to 35, 1.97 mg. for the age group from 36 to 59 and 0.51 mg. for the age group from 61 to 83.

They did not state, however, what their criteria for normal are. We attempted to set up tentative criteria by considering as normal those patients who had both a blood level of 0.7 mg. or over and a five hour urinary excretion of 400 mg. or more after a 1 Gm. test dose. Twenty-six patients fulfilled these criteria. Their

7. Cebione (Merck), supplied by Merck & Co., Rahway, N. J.
8. Greenberg, L. D.; Rinehart, J. F., and Phatak, N. M.: *Proc. Soc. Exper. Biol. & Med.* 35:135 (Oct.) 1936.

values for vitamin C in the spinal fluid ranged from 1.82 to 4.18 mg. We tentatively accepted as normal any spinal fluid containing 1.82 mg. or more of cevitamic acid per hundred cubic centimeters. In the present series we did not note any definite age correlation for our spinal fluid values.

RESULTS

The results of tests on 133 patients are shown graphically in charts 1 and 2. They may be summarized by dividing the cases into three groups on the basis of determinations of the amount of vitamin C in the blood, as follows:

I. Normal group (0.7 mg. or over per hundred cubic centimeters of blood); thirty patients.

A. The vitamin C content of the spinal fluid was normal (1.82 mg. or over) in twenty-nine (97 per cent) of these patients, and the remaining patient had a content of 1.79 mg. The average spinal fluid content for the whole group was 3.05 mg. per hundred cubic centimeters.

B. The five hour urinary excretion test was normal (400 mg. or over) for twenty-six (87 per cent) of the thirty patients. The average urinary excretion for the whole group was 484 mg.

II. Intermediate subnormal group (from 0.4 to 0.69 mg. per hundred cubic centimeters of blood); thirty-five patients.

A. The vitamin C content of the spinal fluid was normal in seventeen (49 per cent) and subnormal in eighteen (51 per cent). The average spinal fluid content for the whole group was 1.82 mg. per hundred cubic centimeters.

Chart 1.—Blood spinal fluid and urinary excretion values for vitamin C in 133 cases graphed in descending order of blood values. Dots on same ordinate represent determinations on same patient.

B. The five hour urinary excretion test was normal for eleven (31 per cent) and subnormal for twenty-four (69 per cent). The average urinary excretion for the whole group was 289 mg.

III. Subnormal group (less than 0.4 mg. per hundred cubic centimeters of blood); sixty-eight patients.

A. The vitamin C content of the spinal fluid was subnormal in fifty-nine (87 per cent) of the sixty-

eight patients. The average content for the whole group was 1.01 mg. per hundred cubic centimeters.

B. The five hour urinary excretion test was subnormal for sixty-seven (99 per cent) of the sixty-eight patients. The average urinary excretion for the whole group was 116 mg.

Chart 2.—Percentage correlation by blood groups.

Analyzing the data on the 133 cases, taking the five hour urinary excretion as one's point of reference, one finds that:

A. Thirty-eight patients had a normal five hour urinary excretion test. The vitamin C content of the blood was normal (above 0.7 mg. per hundred cubic centimeters) in twenty-six (68 per cent) of these thirty-eight patients; eleven of the twelve remaining patients had intermediate subnormal levels (from 0.4 to 0.69 mg. per hundred cubic centimeters), and only one patient had a level below 0.4 mg. The vitamin C content of the spinal fluid was normal in thirty-five (92 per cent) of the thirty-eight patients with a normal urinary excretion test.

B. Ninety-five patients had a subnormal five hour urinary excretion test (less than 400 mg.). The vitamin C content of the blood was subnormal in ninety-one (96 per cent) of these and the content of the spinal fluid was subnormal in seventy-seven (81 per cent).

Analyzing the data on the 133 cases, taking the vitamin C content of the spinal fluid as one's point of reference, one finds that:

A. Fifty-three patients had normal values for the spinal fluid (above 1.82 mg. per hundred cubic centimeters). The values for the blood were normal for twenty-nine (55 per cent) of these, intermediate subnormal (from 0.4 to 0.69 mg. per hundred cubic centimeters) for seventeen (32 per cent) and low (below 0.4 mg.) for seven (13 per cent). The urinary excretion test was normal for thirty-five (66 per cent).

B. Eighty patients had subnormal values for the spinal fluid (below 1.82 mg. per hundred cubic centimeters). The values for the blood were subnormal (below 0.7 mg. per hundred cubic centimeters) for seventy-nine (99 per cent) of these. The urinary excretion test was subnormal for seventy-seven (96 per cent).

We believe that our results indicate that a normal vitamin C content of the blood (i. e., above 0.7 mg. per hundred cubic centimeters) and a very low content (below 0.4 mg. per hundred cubic centimeters) are

almost invariably associated with corresponding normal and subnormal values for both the spinal fluid and the five hour urinary excretion test and that therefore the blood alone in these ranges furnishes an adequate and accurate index of the vitamin C nutrition. In the intermediate subnormal range of vitamin C content of the blood (from 0.4 to 0.69 mg.) no such close correlation exists, and in this range all available means of study, including clinical evaluation of the patient, should be used.

If the excretion of the urine is being studied, our results show that a subnormal five hour excretion test is almost invariably associated with subnormal values for the blood and the spinal fluid. A normal excretion test is almost invariably associated with a normal value for the spinal fluid and a value for the blood above 0.4 mg. per hundred cubic centimeters.

If the vitamin C content of the spinal fluid is determined, our results show that a subnormal value (i. e., below 1.82 mg. per hundred cubic centimeters) is almost invariably associated with a subnormal value for the blood and a subnormal urinary excretion test. A normal value for the spinal fluid may be associated with either normal or subnormal values for the blood and the urine.

COMMENT

The vitamin C values for blood, spinal fluid and urine given in this paper are not absolute values. The methods of assay of vitamin C are constantly changing, and the accepted values will change according to the method used. At the time this study was undertaken the method of Farmer and Abt appeared to be the most accurate available. This method measures only the reduced cevitamic acid. The method of van Eekelen, in which it is assumed that vitamin C exists in blood in both the reduced and the reversibly oxidized form (dehydro-ascorbic acid), uses reduction of the supposedly present dehydro-ascorbic acid with hydro-sulfuric acid. This supposed added reduction (with consequently higher values for vitamin C) has been criticized by Kellie and Silva⁹ as an artefact.

Recently Pijoan and Klemperer¹⁰ have published a study showing that in the method of Farmer and Abt a loss of vitamin C occurs through oxidation, both before and during titration. This loss, they stated, can be prevented by the addition of potassium cyanide to the blood as soon as it is drawn from the vein. It should be noted, however, that their normal range of values for vitamin C in the blood (from 0.65 to 2.0 mg. per hundred cubic centimeters) agrees with our own very closely. In addition, our determinations on the blood were all done less than one-half hour after the samples were obtained. Taylor, Chase and Faulkner,¹¹ using a method of precipitating the plasma with sodium tungstate and sulfuric acid (similar to the method of Farmer and Abt), found that added yields of as much as 100 per cent are obtained by redissolving the precipitated plasma in excess sodium tungstate and reprecipitating with sulfuric acid, adding the washings at each reprecipitation. Iodometric¹² and methylene blue titration¹³ and spectroscopic methods¹⁴ for estimation of vitamin C also have been described by other investigators.

We have had no experience with any of these methods, and, as before stated, we make no claim for the absolute accuracy of our results. Furthermore, it should be remembered that our results apply only to relatively stable patients. We do not know if they are applicable to patients who have recently received unaccustomed, large doses of vitamin C or who have recently been subjected to sudden deprivation of the vitamin. With these qualifications we do feel that our values for blood, spinal fluid and urinary excretion are accurate in relation to each other and that our results demonstrate a close parallelism between these values in the ranges stated.

Since this parallelism exists, we believe that values for the blood, if they fall within the ranges of normality or of marked hypovitaminosis (i. e., below 0.4 or above 0.7 mg. per hundred cubic centimeters) provide a sufficient and accurate index of the vitamin C nutrition. The advantages of any test that utilizes the blood instead of the spinal fluid or the results of the laborious five hour urinary excretion test are obvious. However, in the intermediate range of subnormal values for the blood (from 0.4 to 0.69 mg.) all available methods of study are advisable.

Six patients in our series had clinical scurvy and all presented extensive purpura (with normal platelets, bleeding time and clotting time). Four of the six had typical hyperplastic granulations on the gums, while the remaining two showed only marked gingivitis. The vitamin C content of the blood ranged from 0.22 to 0.3 mg. per hundred cubic centimeters, the content of the spinal fluid from 0.25 to 0.42 mg. per hundred cubic centimeters and the five hour urinary excretion from 53 to 149 mg. The determinations for six of our patients who presented none of the clinical features of scurvy were all within the range for scurvy. The diagnosis for these six were Laënnec's cirrhosis (two cases), carcinoma of the stomach, essential hypertension, psychoneurosis and pernicious anemia. In addition thirty-seven patients had values for the blood below 0.31 mg. per hundred cubic centimeters, sixteen had a urinary excretion below 149 mg., six had values for the spinal fluid below 0.42 mg. per hundred cubic centimeters and all of them were without purpura or typical scorbutic gums. Perhaps it is necessary that such low levels exist for a considerable period before the clinical manifestations of scurvy develop.

Scurvy is a clinical entity. Its diagnosis may be confirmed by vitamin assay, but no specific level of vitamin C at any given moment in blood, spinal fluid or urinary excretion is necessarily associated with the clinical manifestations of scurvy.

SUMMARY AND CONCLUSIONS

The vitamin C content of the blood, of the spinal fluid and of the five hour urinary excretion after a 1 Gm. intravenous test dose of cevitamic acid were determined for 133 patients.

1. A blood content of vitamin C above 0.7 mg. per hundred cubic centimeters (by the method of Farmer and Abt) is almost invariably associated with a normal spinal fluid content and a normal urinary excretion test for vitamin C. A blood content of vitamin C below 0.4 mg. per hundred cubic centimeters is almost invariably associated with a subnormal spinal fluid content and a subnormal urinary excretion test. In these ranges the blood is an adequate and accurate index of the state of vitamin C nutrition.

2. In the intermediate subnormal range for blood (from 0.4 to 0.69 mg. per hundred cubic centimeters) all available tests should be used, including clinical evaluation of the patient.

3. Scurvy is a clinical entity, and its diagnosis cannot be made by vitamin C determinations alone.

CYSTIC HYGROMA OF THE NECK

BRUCE L. FLEMING, M.D.

PHILADELPHIA

A hygroma is a thin-walled cystic tumor containing lymph and lined with endothelium. It occurs most commonly in the side of the neck in the lower half. Occasionally it extends into the mediastinum. These tumors are usually made up of several cysts and are then described as lobulated. Capillary and cavernous types, however, occur in children. Hygromas also have been found in the axilla and groin, but these are rare. Hygromas of the neck appear most frequently during the first two years of life, but they may develop at any time. They grow rapidly.

Dowd¹ collected reports of ninety-one cases in 1913. Only seven of these were in adults, whose ages ranged from 19 to 37 years. Vaughn² in 1934 reviewed all cases recorded in the literature since 1913. They numbered sixty-four cases. Only ten of these were in adults, whose ages ranged from 18 to 36 years. MacGuire³ in 1935 reported eight other cases. Two of these were in adults. Thus only nineteen cases in adults appear in 163 recorded in the literature. Two more such cases are reported herein.

It seems quite definitely established that hygromas grow from the lymph sacs known to appear in the neck in the embryologic development of the lymphatic system. The origin of these lymph sacs is still a matter of controversy. Sabin⁴ has found that the lymphatic system begins in the human embryo during the sixth week of development. "These first lymphatics are blunt buds which come from the internal jugular vein at the root of the neck. These buds grow together and form a large sac which is attached to the internal jugular vein and extends into the posterior triangle of the neck." McClure⁵ believes that these lymphatic sacs appear independent of the blood vascular system and become attached to the internal jugular veins later in development. He says "The general principle of the local genesis of intra-embryonic endothelium from mesenchyme may now be regarded as an established fact." McClure and Huntington believe that in certain cases some of these structures may never connect with the veins but give rise to hygromas. This is the generally accepted theory of their origin.

Cystic hygromas have very thin walls of fibrous tissue lined with endothelium, which is readily stained with silver nitrate so that the cellular arrangement may be seen. These lining cells differ from the endothelial cells which normally line lymphatic capillaries.⁶ The latter

are usually thinner. They do not differ structurally from the endothelial cells lining the main group of blood capillaries.

The function of the lining endothelium of lymph capillaries is essentially absorptive and that of the blood capillaries is both productive and absorptive. In hygromas the lining cells seem to resemble functionally the endothelium of blood capillaries, for in all probability they produce the lymph which fills the cysts. No other source has been determined. This lymph may be tinged with blood though it is usually straw colored. Rudimentary forms of lymph "gland" tissue containing both lymphatic capillary network and blood vascular tissue is sometimes found attached to hygroma colli. This lymph gland tissue⁷ develops from plexuses of lymph vessels. The phagocytic power of lymph gland tissue is well known. Evidence, however, of the phagocytic power of lymph vessel endothelium is negligible.⁶

Appearance of hygroma in case 2 before complete excision.

Hygromas usually do not give rise to troublesome symptoms other than those of tumor. They may, however, grow to considerable size in infants and children and thus cause marked dyspnea. They have been mistaken for branchial cysts, lipomas, tuberculous glands, lymphangiomas, lymphomas and carotid tumors. Hygromas of the neck are usually lobulated and appear on the side and usually in the lower half of the neck. They are not attached to the skin but rather to the deep structures. Signs of inflammation are lacking. They transmit light. Aspirations reveal lymph, which may be almost completely removed, but refilling occurs rapidly. The diagnosis should not be difficult.

The treatment of hygroma colli is complete surgical excision. If the tumor extends into the mediastinum, this may be difficult and dangerous. Under such circumstances partial excision and packing may be done with excellent permanent results. Radium treatment

has been tried in children. Figi⁸ reported thirteen such cases, in three of which a cure was obtained. Three patients were improved and seven died of infection. Radium treatment must extend over a long period of time. Aspiration of the fluid contents followed by injection with a sclerosing solution has been attempted. This treatment is not satisfactory for multilocular tumors because the larger cysts do not communicate.

Two adults have been treated for this condition in the Jefferson Hospital since 1908:

REPORT OF CASES

CASE 1.—A. B., a woman, aged 40, admitted to the hospital Sept. 7, 1908, complained of a lump on the right side of her neck. There was a history of tuberculosis in the mother and father. Fifteen years previous to admission the patient had a mass on the right side of the neck, which was incised and drained. She said it contained pus. After a long period of rest in bed the wound healed completely. A year and a half before admission a small lump appeared near the site of the previous mass. Growth was slow until four months before admission. Since then it had grown rapidly. The patient was poorly developed and was emaciated. The throat was normal. On the right side of the neck was a rounded mass, which extended from the mastoid process posterior to the sternocleidomastoid to a point $1\frac{1}{2}$ inches above the clavicle. It was irregular, soft and fluctuating, but there were no signs of inflammation. The temperature, pulse and respiratory rate were normal. Excision was done by Dr. E. J. Klopp, September 8, under ether anesthesia. Incision was made along the posterior border of the sternocleidomastoid muscle, which gave approach to three cysts attached to but not communicating with it. One was ruptured in removal. The wound was drained but healed completely in fifteen days. The unruptured cysts were sent to the pathologist. His report was as follows: The specimen consisted of two globular masses, clearly cysts, 5 by 2.5 cm. in diameter. The outer walls were smooth and very thin. Incision revealed amber colored fluid containing considerable white granular greasy substance. The microscopic examination revealed that the walls of the cyst were composed of dense, wavy, fibrous tissue. In one area this tissue contained a small, encapsulated collection of lymphoid tissue. The lining of the cyst was smooth and no epithelium was observed. In areas there was a single layer of flattened cells which was considered to be endothelium.

The diagnosis was cystic hygroma.

CASE 2.—L. L. S., a man, aged 28, had always been in good health save for an anal fistula, which was removed by operation in 1919. In 1925 he first noticed a swelling in the lower part of the neck on the left side. This increased rapidly to its present size. Several aspirations were done. A yellow serous fluid was removed, but the tumor promptly regained its original size. The only other symptom was mild pain referred down the arm. This was felt after the arm was lifted.

Examination previous to operation revealed a large tumor just above the left clavicle not attached to the skin, as shown in the accompanying illustration. It was lobulated, gave a sense of fluctuation and was fixed to the deep structures of the neck. There was no local heat or other evidence of inflammation. The tumor transmitted light. The temperature and pulse were normal. A diagnosis of hygroma was made.

Oct. 22, 1927, I completely removed the tumor under ether anesthesia. It was made up of thin-walled cysts containing lymph and was attached to the deep vessels of the neck. The cysts were ruptured and completely emptied during operation, but drainage was not needed and the wound healed promptly. Dr. Baxter L. Crawford studied the specimen microscopically. His report was as follows: The walls of the large cysts were very thin and composed of connective tissue of loose texture and fat. Numerous small capillary-like vessels, some of which contained blood, were scattered through the connective tissue. The lining was smooth in areas with a single layer of flattened endothelial cells covering the surface. In other areas the

surface was more irregular, with small projections into the cavity. In the surrounding connective tissue there were numerous small similar cysts. No lymphoid tissue or evidence of inflammatory reaction was noted.

The diagnosis was cystic hygroma.

There had been no recurrence of the condition ten years after operation.

SUMMARY

Hygromas of the neck are thin-walled cystic tumors lined with endothelium and containing lymph. They grow from lymph sacs or buds that appear, in embryologic development near the junction of the internal jugular and subclavian veins.

The endothelial cells lining these tumors are structurally different from and thicker than those lining lymphatic capillaries. They are structurally the same as blood capillary endothelial cells, which they resemble functionally, for they apparently produce the contained lymph. Evidence of phagocytic power is negligible. The diagnosis is not difficult. These tumors rarely develop in adults. The treatment is complete surgical excision or partial excision and packing.

STUDIES IN THE EVALUATION OF MAMMOGRAPHY

RALPH A. REIS, M.D.

AND

SIDNEY D. MESIROW, M.D.

CHICAGO

The utilization of opaque substances in the diagnosis of disorders of the breast has been the subject of several enthusiastic reports in the recent literature. Hicken and his co-workers¹ have reported 350 injections of the lactiferous ducts for diagnostic purposes with only two mishaps; namely, multiple abscesses of the breast following injections in the presence of acute mastitis. Their study led them to conclude that mammography is both efficient and safe.

Hicken compares the use of colloidal thorium dioxide, lipiodine-Ciba, hippuran (Mallinckrodt), diodrast (Winthrop), bismuth oxychloride (Mallinckrodt), 15 per cent sodium iodide, and air. He believes that colloidal thorium dioxide is the least irritating and most suitable because its fluidity permits the filling of the smallest lacteal ducts and acini and yet it is of sufficient density to cast satisfactory shadows.

The technic recommended is as follows:

The breast is thoroughly cleansed as for any surgical procedure. Gentle massage of the nipple expresses small droplets of secretion or inspissated plugs of material from the lactiferous ducts. In this manner, the openings of the ducts are accurately located and can be readily cannulized by a blunt no. 25 gage needle. The contrast fluid is then injected into the duct until a sense of discomfort is experienced by the patient. This is repeated until all available ducts, usually eight or ten, have been injected, and then stereoscopic roentgenograms are taken.

The combined appeal of safety, simplicity and accuracy of diagnosis led to similar investigations in a series of patients with suspected disorder. The technic, as

Read before the Chicago Gynecological Society, Dec. 17, 1932.

recommended, was followed carefully. Excellent roentgenograms of the ductal system of the breast were obtained in almost every instance.

There is no doubt as to the diagnostic value of the procedure. Nor can there be any question of its safety when injection is followed by surgical removal of the involved breast. The question of the fate of colloidal

Fig. 1 (case 1).—On successive examinations the colloidal thorium dioxide was unchanged in the breast for seven months; A, film taken Feb. 8, 1937, at the time of the injection of the contrast medium; B, February 19; C, March 21; D, September 21.

thorium dioxide and its effect on breast tissue when the breast is not removed following injection has not been studied.

Hickens states that the terminal protective sphincter which guards the ductal orifice prevents the injected colloidal thorium dioxide from escaping and that the colloidal thorium dioxide may remain in the breast for as long as five months after injection; furthermore, that "thorotrast has but a very mild tissue reaction and can be used with complete safety."

Thorotrast (Heyden) is a stabilized 25 per cent solution of colloidal thorium dioxide. Its chief value lies

Even smaller quantities of thorium dioxide sol will produce marked local tissue changes. Selbie⁴ injected 1.3 cc. of this product into the flank of each of sixty rats. He found that the thorium dioxide sol had remained localized in firm, yellow nodules on section, such nodules showed many macrophages which had ingested the colloidal thorium dioxide in the form of highly refractile, deep yellow granules. After following these rats carefully for fifteen months, he found that there were definite tumors in fourteen. Each such tumor proved to be a typical spindle cell sarcoma. Furthermore, autoplasts were successful in five and transplantation was successful in two.

Colloidal thorium dioxide owes its carcinogenic properties to its disintegration products, which maintain their radioactivity for years. The danger lies in the highly destructive activity of the alpha rays that are given off. Furthermore, the disintegration products are mesothorium and radiothorium, the two main constituents of luminous paints which produced fatal poisoning as well as osteogenic sarcomas in dial painters as the result of ingestion.⁵ The importance of particle radiation should be stressed. An examination of particle equivalents, as pointed out by Meyer,⁶ is given in the accompanying table.

A number of patients in the series under discussion were subjected to mammography, with colloidal thorium dioxide serving as the contrast medium. In none of those under consideration was it necessary to follow the roentgen studies by immediate surgery, and the opportunity was therefore seized for follow-up roentgen studies to determine the fate of the injected colloidal thorium dioxide and of the breast tissue itself. Repeat roentgenograms were taken every few months after it became obvious that the material was remaining unchanged for a long time. In each instance the

Fig. 2 (case 2).—A, original film taken Nov. 24, 1937; B, colloidal thorium dioxide unchanged after ten months.

in the fact that it is opaque to roentgen rays and throws a deep shadow in roentgenograms. Being miscible in all proportions in body fluids, it has been introduced into various body cavities and into the general circulation with no immediate harmful effects. A recent editorial² calls attention to the dangers of its use, especially when the solution remains in the body for any length of time. This danger results from its most important characteristic: its radioactivity. This editorial further points out that the degradation products of thorium emit alpha rays more penetrating than those of the radium series and that this ray is about 10,000 times as toxic to tissues as the gamma ray which is used therapeutically. Taft³ measured the gamma ray equivalent of 75 cc. of thorium dioxide sol by means of the Geiger counter and found it to be the equivalent of 1.37 micrograms of radium. Since 2 micrograms has produced symptoms of radium poisoning, the margin of safety would appear to be too small when a full 75 cc. of colloidal thorium dioxide is used.

shadows remained relatively unchanged even when as much as one year had elapsed since the original injection.

CASE 1.—Mrs. F. V., aged 40, a widow, complained of a slight bloody discharge from the left nipple. This followed a series

of injections of estrogenic substance for the relief of rather severe postirradiation menopausal symptoms. Thorium dioxide was injected on Feb. 8, 1937. No abnormality was noted on the original films. Repeat roentgenograms were taken on February 19, March 21 and September 21. Comparison of these films (fig. 1) shows the colloidal thorium dioxide to be unchanged for the entire seven month period. The patient complained of constant dull pain in the breast together with tenderness.

Fig. 3 (case 3).—A, original film taken at the time of injection, April 10, 1937; B, film taken August 17; C, film taken October 27.

CASE 2.—Mrs. J. H., aged 58, complained of a slight bloody discharge from the left nipple for two days. This also followed repeated injections of estrogenic substance for the relief of menopausal symptoms. Eight cubic centimeters of colloidal thorium dioxide was injected on Nov. 24, 1937. The films taken revealed no pathologic changes. Ten months later the patient complained of continuous pain in the left breast together with considerable tenderness. Examination revealed the breast tissue to be nodular and sensitive. Repeat roentgenograms showed the colloidal thorium dioxide to be unchanged since the original injection ten months previously (fig. 2). There was a tender mass about 4 cm. in diameter lying just beneath the nipple and areola. This was excised. Healing was delayed for about four weeks—there being a low-grade infection present with continuous viscid and oily discharge. The wound healed by secondary intention. The remaining breast tissue remains sensitive.

CASE 3.—Mrs. F. S., aged 42, married, had an injection of colloidal thorium dioxide (7 cc.) into the right breast on April 10, 1937. The roentgenograms revealed no pathologic changes.

Fig. 4 (case 2).—Tissue removed from cut surface. This shows small irregular mass with no capsule or definite line of demarcation. Cut surface is smooth and white.

Repeat films were taken on August 17 (fig. 3), at which time the patient complained of pain in the breast and tenderness. The breast was sensitive to clothing and the patient was in constant discomfort. The roentgenograms showed the colloidal thorium dioxide to be practically unchanged in appearance. Nine weeks later (October 27) films were again taken and no changes were noted. The large accumulation of colloidal thorium dioxide and the surrounding breast tissue were excised at this time because

of the constant pain and discomfort. This incision also healed very slowly, there being a constant viscid discharge from the wound, accompanied by an apparently indolent infection. Healing was not completed for five weeks following operation.

Five of the patients who were followed complained of persistent pain in the injected breast. This, combined with a moderate degree of tenderness and sensitivity to clothing, caused persistent and annoying discomfort. Patient 2 complained of constant drainage from the nipple for eight months in addition to the symptoms mentioned, and finally patients 2 and 3 presented firm, tender and painful nodules after ten and six and one-half months, respectively. These nodules were such a source of discomfort to these patients and caused such mental unrest because of the cancerphobia which developed that it was deemed advisable to remove them by surgical excision.

In each the tumor, which was sharply defined on palpation and transillumination and seemed sharply defined on follow-up roentgenograms, proved to be irregularly defined and difficult to outline when the breast was incised. Each was then removed by wide dissection and the incisions were closed without drain-

Fig. 5 (case 2).—A, roentgenographic appearance of tissue removed; B, appearance when film was exposed to excised tissue and lower half shielded by lead plate.

age. Both incisions broke down during the second post-operative week, drained a seropurulent oily material for several weeks and healed very slowly and very poorly. Apparently the tissue changes produced delayed healing to a considerable degree.

The tissue removed in case 2 was studied for opaque material by roentgenograms, for radioactivity by means of exposure of tissue to x-ray films and the Geiger counter,⁷ and histologically.

Figure 4 shows the tissue removed. The mass measured about 2 by 2 by 1 cm. On section it presented a smooth white surface which seemed oily. It was poorly demarcated, presenting no capsule.

Figure 5 A shows the x-ray appearance of the tissue, while figure 5 B is a reproduction of an x-ray film the upper half of which was exposed to the tissue while the lower half was protected by lead foil. It should be noted that the darkening in the upper portion of the film and the distribution of the darkening corresponds to the areas of greatest concentration of the opaque material.

This block of breast tissue was tested for radioactivity by means of the Geiger counter,⁸ and a com-

7. Taft, R. B.: Technical Data Concerning the Geiger Counter. Radiology 26: 756-757 (June) 1936.
8. Bowers, B. F., and Masson, J. C.: Mastitis Following the Use of Thorium Oxide, Proc. Staff Meet., Mayo Clinic 12: 522 (Aug. 25) 1937.

parison was made of the gamma ray output of the excised breast tissue with 2 cc. of colloidal thorium dioxide. It was determined that 16 Gm. of breast tissue contained the equivalent of 0.55 Gm. of thorium dioxide or 2.25 cc. of colloidal thorium dioxide.

Thus the colloidal thorium dioxide injected into the breast under consideration remained definitely radioactive for ten months, from Nov. 24, 1936, to Sept. 21, 1937, at which time it was removed.

Microscopic examination of the removed breast tissue by Dr. Otto Saphir revealed the following changes: Sections stained with hematoxylin and eosin showed numerous cords or nests of pigmented cells separated by thin strands of dense hyalinized connective tissue. In the peripheral parts of this lesion occasional distorted lobules and isolated ducts or acini were often associated with a granulomatous response. Bordering the lesion, several lobules of normal breast tissue were noted (fig. 6). On close examination the cords of cells were

Fig. 6 (case 2).—Section of tissue $\times 80$. Note the nests of pigmented cells separated by dense hyalinized connective tissue, occasional distorted lobules and isolated ducts. Giant cells can also be seen.

composed of polygonal, usually well demarcated, cells with pyknotic, usually eccentric, single nuclei and cytoplasm replete with grayish tan granules, which varied moderately in size and shape (fig. 7). These appeared in unstained preparations as tan, partly refractile, isotropic granules. They did not react with the sudan III stain for fat or with the prussian blue stain for iron pigment. In some areas the individual cell boundaries were lost and the granules appeared strewn in a connective tissue stroma. Elsewhere in an unusual focus a slight to moderate degree of necrosis was observed. In such areas, and also associated with the inflammatory reaction to be mentioned, small foci of calcification were noted. The granulomatous response consisted of foci of lymphocytes often closely related to breast ducts or acini in which were numerous irregularly shaped, large, multinucleated, usually nonpigmented giant cells. These contained up to approximately thirty nuclei distributed at random throughout the cytoplasm (fig. 8).

The removal of the nodule in case 3 afforded the opportunity of studying the effect of the radioactive

material on breast tissue after a shorter period of time (six and one-half months). The nodule contained opaque material as shown by roentgenogram and by histologic studies by Dr. Otto Saphir. Section revealed

Fig. 7.—Appearance of section magnified 128 diameters. Note the giant cell formation, round cell infiltration, hyalinized connective tissue and areas of necrosis.

nests and cords of pigmented cells separated by a hyalinized connective tissue stroma as in the previous specimen with the absence, however, of granulomatous

features. By the use of hematoxylin-eosin stain the cells appeared polygonal or oval, contained eccentric, hyperchromatic single nuclei and were filled to capacity with irregular, coarse grayish tan granules. Foci of

cellular disintegration and necrosis were not observed. The granules were easily visible in the unstained preparations and did not take the sudan III or prussian blue stains nor did they react positively as bile pigment. They were nonrefractile in a field of polarized light. A rare, fairly normal appearing breast duct was observed on the

Fig. 9 (case 3).—Discharge from nipple magnified 304 diameters.

periphery of the lesion. Examination of the secretion from this breast revealed round or oval pigment containing cells resembling in appearance and in staining reaction the described cells within the breast (fig. 9).

Case 4 is made available through the courtesy of Dr. J. C. Masson of the Mayo Clinic and has been reported previously:⁸

CASE 4.—A white woman, aged 41, unmarried, admitted to the Mayo Clinic for the first time Jan. 11, 1937, complained of pain, soreness and a movable hard lump in the lower half of the abdomen. On examination a large pelvic-abdominal tumor and chronic cystic mastitis of the left breast were discovered. Simple mastectomy of the right breast had been performed elsewhere in 1932.

Abdominal exploration was advised and carried out January 12, at which time total abdominal hysterectomy, bilateral salpingectomy, left oophorectomy for chronic cystic oophoritis and appendectomy were performed. Convalescence was uneventful and the patient was dismissed from the clinic on the twenty-first postoperative day and given instructions to have periodic examinations of the left breast. She continued to improve after dismissal.

The patient returned to the clinic May 21 because of pain in the left breast. She stated that one month previously she felt the left breast and thought the lumps were getting larger. She consulted her physician, who injected thorium dioxide into the left nipple with a hypodermic needle and syringe on May 3. A roentgenogram was made and no tumor was visualized. The patient had pain and soreness extending into the axilla immediately following the injection. She consulted her physician again on May 18, fifteen days after the injection, and it was suggested that the breast be incised. She then decided to return to the clinic. The left breast was found to be hardened, red and tender. A roentgenogram of the thorax revealed evidence of radiopaque material in the left breast. Detailed roentgenologic examination of the left breast revealed evidence of thorium in the ducts. No filling defects or tumors could be seen. The appearance suggested normal mammary structures and an exces-

sive amount of thorium. Simple mastectomy was advised and carried out by Dr. J. C. Masson on May 25, twenty-two days after the injection of colloidal thorium dioxide. Pathologic examination revealed a chronic mastitis with extensive fat necrosis; the cells contained granules of thorium. Convalescence was uneventful. The patient was dismissed from the hospital on the sixth postoperative day.

Microscopic study by Dr. Otto Saphir showed the following: Section consisted of two pieces of tissue, one of which demonstrated large plaques of granular cells in a fine connective tissue matrix. In several regions unchanged ducts were observed (fig. 10). Others were associated with a few lymphocytes and some were closely surrounded by the granular cells. In one duct such cells were noted free in the lumen. The granular cells were oval, round or polygonal and consisted of a coarsely and irregularly granular, almost colorless, cytoplasm and a central stippled fairly well demarcated nucleus. In some foci cell boundaries and nuclei were indistinct and masses of granules were apparently free in the connective tissue.

COMMENT

Three patients suffered pain and tenderness of the breast following injections of colloidal thorium dioxide into the lacteal ducts for diagnostic purposes. The fourth patient had an acute mastitis with tissue necrosis of a degree sufficient to require mastectomy. Follow-up roentgenograms showed the colloidal thorium dioxide lying unchanged in the lacteal ducts for as long a period as ten months after the original injection. In two of these the discomfort warranted the removal of the involved tissue for relief.

This tissue contained the colloidal thorium dioxide, which remained definitely radioactive. The particle emission of thorium is comparable if not equal to that of radium. No one, it is felt, would advocate the local introduction of unfiltered radium element or solution

Fig. 10 (case 4).—Eccentric cells with granular cytoplasm and granules free in connective tissue ($\times 76$).

into living tissue. It would seem that the use of radioactive material such as this is fraught with definite danger in spite of the considerable quantitative difference in particle emission.

The retained colloidal thorium dioxide provoked a marked and apparently characteristic tissue reaction characterized by a typical foreign body reaction. In

addition there was tissue necrosis corresponding roughly to the length of time that the tissue was exposed to the colloidal thorium dioxide. Case 4, following the retention of the colloidal thorium dioxide for four weeks, showed macrophage infiltration plus a few areas of tissue necrosis in which the cell boundaries and nuclei were somewhat indistinct. The tissue taken in case 3 was exposed to the colloidal thorium dioxide for six and one-half months. Here there was the same macrophage infiltration but to a more marked degree together with a more definite connective tissue hyalinization. Case 2, following exposure to colloidal thorium dioxide for ten months, showed many larger areas of tissue necrosis, more hyalinization and a marked giant cell infiltration as well as the largest number of macrophages.

CONCLUSIONS

1. Colloidal thorium dioxide injected into the lacteal ducts for purposes of mammography remains unchanged for many months and is the source of considerable physical and mental discomfort to the patient.

2. Thus injected, it remains radioactive.

3. Histologic studies suggest the progressive development of a granulomatous change in response to the presence of a foreign material, which is radioactive together with a varying degree of tissue necrosis.

4. In view of the observations made, mammography by means of colloidal thorium dioxide would seem to be fraught with potential danger and therefore to be an unsafe procedure.

THE LIMITATIONS AND DANGERS OF MAMMOGRAPHY BY CONTRAST MEDIUMS

SAMUEL ANDREW ROMANO, M.D.

AND

ELIZABETH M. McFETRIDGE, M.A.

NEW ORLEANS

More than one writer has called attention to the fact that the very results of the campaign to educate the public in the facts of cancer have placed a heavy responsibility on the medical profession. The figures from the Halsted Clinic are typical. During its early years, as the late Joseph Colt Bloodgood noted in one of his last papers, more than 80 per cent of the tumors of the breast treated in it were malignant, whereas in later years almost 90 per cent were benign. That did not mean, he hastened to explain, that the incidence of malignant tumors was decreasing; it merely meant that more and more women were seeking advice for conditions which they had formerly ignored. As this trend has continued, there has come to the physician's attention an increasingly large group of borderline cases in which diagnosis is difficult and the result of diagnosis momentous. It is this group of cases which supplies the impetus for new methods of diagnosis and which is chiefly responsible for the enthusiasm with which all such methods are hailed and employed.

The most recent of these methods is mammography, which is the radiographic demonstration of tumors of the

breast after injection of the ducts with some opaque medium. It was first mentioned in the literature in 1930, when Ries¹ reported a single case in which iodized poppy-seed oil was employed, but does not appear again until the spring of 1937. Then Hicken and his associates² at the Nebraska College of Medicine reported the use of this method in fifty-six cases, in which 314 pictures had been made over a period of eighteen months. A few injections were made with iodized oil, but stabilized colloidal thorium dioxide (thorium dioxide sol, thorotrast-Heyden) was used in most of the cases.

In his first communication Hicken stated that by this method it is possible to differentiate localized from infiltrating growths, solid from cystic tumors, and simple retention cysts from cystic degeneration of the breast. He considered it particularly valuable in determining the location, number and size of papillomatous tumors but did not advise it for frankly malignant growths or in cases in which acute infection was present; his only untoward result was in such an acute case. Subsequent communications on the subject, the most recent in December 1937,³ are to substantially the same effect. The author and his associates are conservative in their expressions, but they leave no doubt of their conviction of the value of this method.

Hicken also leaves no doubt of his conviction that stabilized colloidal thorium dioxide is a harmless agent for this purpose. He says:

If there is a hazard in such procedures [the intravenous use of colloidal thorium dioxide], it does not exist in mammography, for the injection is not intravenous but into the mammary ducts, which are normally excretory in function; the Thorotrast does not get into the blood stream. In addition, the quantity injected is considerably less than that used for visualization of the liver and spleen, and the mammary ductal tissue has very low if any absorptive powers, so the amount that could be absorbed would be practically nil. Much of the Thorotrast can be removed from the injected ducts by lavaging with saline solution and then evacuating by means of a breast pump. The quantity of the medium that might remain after these cleansing irrigations is so small that apprehension concerning its harmful effect is entirely unwarranted. No untoward reactions from Thorotrast have been encountered in the series of mammographs we have made.

Primarily to establish the practical value of mammography in the diagnosis of conditions, we undertook its use in a series of patients admitted to our services in the New Orleans Charity Hospital. Our study, however, soon entered on a phase which we had not planned, and as a result we are reporting herewith not so much the diagnostic implications of this method as the risks associated with it, of which the literature now available gives no real conception.

Our material consists of twenty-five clinical cases in which eighty-five pictures were taken. In addition, we used the method on twenty-eight breasts in four experimental animals. The study of normal breasts which we had planned as a control series was not carried out because of the reactions that occurred in some of our earliest cases following the injections. We have, therefore, only two nonsurgical cases; in one there is a

From the Department of Surgery of Louisiana State University Medical Center and the surgical services of the School in Charity Hospital in New Orleans.

The members of the Department of Radiology in Charity Hospital (Dr. Amédée Granger, director), the members of the Department of Pathology in the Louisiana State University Medical Center (Dr. Rigney D'Amoy, director) and Dr. D. D. Baker of the Department of Anatomy of Louisiana State University assisted in this study.

lactating breast and in the other a large pendulous breast. Neither reveals any significant appearance.

We followed practically without change the technic of injection described by Hicken. The patient was given the usual careful general and local examination at the time of admission, and a plain roentgenogram of the

plate under the breast, the patient standing or sitting as was most convenient, and the lateral view with the breast supported by Meyer's angle board.

Operation was done in twenty-three of the twenty-five cases, either by us or under our personal observation. Radical mastectomy was done in seven cases, simple amputation of the breast in three cases and simple excision of the tumor in thirteen cases. The gross specimen was examined and photographed, and the sections were studied with the pathologist in an attempt to correlate the x-ray appearances with the changes revealed grossly and microscopically. In most of the twenty-three surgical cases operation was done within two or three days after the injection. It was deferred for a month in one case because the patient had diabetes, which was rather difficult to stabilize.

In thirteen of the twenty-three surgical cases the mammographic diagnosis corresponded with the clinical diagnosis and was later confirmed in the laboratory. It is not unfair to say, however, that in none of this group of cases did the use of this method add anything of great value to our knowledge. Furthermore, as the following cases show, possible misinterpretation of the radiographic studies might have given rise to serious consequences had they been relied on alone.

REPORT OF CASES

Patient 1 (B. F., a white woman aged 57) complained of bleeding from the left nipple for two months. Examination revealed a painful, movable, semisolid mass, 4 cm. in diameter, in the lower outer quadrant of the left breast; pressure on it caused bright red blood to exude from the nipple. X-ray examination after the injection of the ducts of the affected quadrant

Fig. 1.—A, B, and C (case 1), intraductal and intracystic papillomas of the left breast revealed by mammography, which failed to reveal an early carcinoma in the same quadrant. D (case 2), advanced carcinoma. E (case 3), advanced carcinoma.

breast was made. Our experience with this type of radiographic examination of the pathologic breast is not extensive, but, such as it is, it does not impress us as of value in the borderline cases, the variety in which some diagnostic aid would be most welcome. Then, under aseptic surgical precautions, from two to four ducts of the involved quadrant of the breast were injected with the opaque medium, which was introduced by means of a blunt no. 25 gage hypodermic needle. If the orifice of the duct could not be identified by the expression of droplets of secretion, the needle was introduced by direct vision. Slight pressure was required to introduce it into the duct, but, once it had entered, it usually continued down into the duct by its own weight. The injection was continued until the patient complained of pain; in no case was more than 0.5 cc. used in a single duct, and only 0.25 cc. was injected in many cases. Iodized oil was used in one case, but we found it less satisfactory than stabilized colloidal thorium dioxide, which was used in all the other cases; even when the solution was warmed to body temperature its extreme viscosity made injection difficult.

X-ray examination was made within one or two hours after the injection, though equally satisfactory pictures can be obtained after a longer time. Since it was not possible for us to employ the stereoscopic films advocated by Hicken, we substituted vertical and lateral views. The vertical view was taken with the x-ray

Fig. 2 (case 6).—Foreign body reaction (mild) in cystic disease caused by the injection of an opaque substance. Note the granules of thorium dioxide in the lumen of the duct.

revealed (fig. 1 A, B and C) a marked dilatation of the injected ducts and a clearly defined, large cyst; negative shadows within the dilated ducts and the cyst suggested the presence of generalized intraductal and intracystic papillomas. The x-ray diagnosis was confirmed in the laboratory following simple mastectomy. But the laboratory also detected an early carcinoma.

This possibility had naturally been considered clinically, but nothing in the roentgenogram, even when it was carefully restudied, suggested the condition. This case seems particularly significant in view of Hicken's repeated emphasis on the value of mammography in the diagnosis of papillomas.

Case 5 is another instance in which mammography furnished no clue to the presence of the malignant tumor

Fig. 3 (case 1).—"Shotty" right breast, corresponding to the left breast (fig. 1 A, B and C) in which mammography failed to reveal a malignant growth. B, foreign body reaction (marked) caused by the injection of an opaque substance into the right breast.

that was found to exist. A Negress aged 40 had a firm, irregular, somewhat fixed mass in the lower inner quadrant of the left breast which was clinically malignant and for which radical amputation was done. In case 2 (E. J., a Negress aged 67) and case 3 (R. G., a Negress aged 65) the diagnosis of malignancy was easily made from the mammographs (fig. 1 D and E), but in each instance the growth had advanced to such a point that clinically there was no doubt as to its nature.

Case 4 (E. DeC., a Negress aged 48) and case 18 (L. P., a Negress aged 39) are excellent illustrations of the difficulty of diagnosing possible malignant growths by this method. In case 4 the condition was clinically malignant. The patient had a hard, nodular, fixed mass, 3 cm. in diameter, in the upper part of the left breast; it had been present for about six months. X-ray study of the injected breast showed a faint soft tissue shadow in the upper portion. Many ducts in this area were blocked, apparently by the tumor, and others were displaced. The ducts in the middle and lower portions of the breast were dilated. In view of the clinical observations it was considered that the abnormalities revealed by the roentgenogram were due to malignant periductal infiltration, and the diagnosis of a malignant growth was confirmed by the laboratory. In case 18 the history, the physical examination and the absence of fixation suggested a benign condition, but the roentgenogram revealed the same type of dilatation and blockage of the ducts noted in the malignant tumor just reported. In this case the abnormality was evidently caused by the notable increase in fibrous tissue revealed on microscopic study, which confirmed the clinical and operative diagnosis of benign cystic disease.

In the nine cases of cystic disease studied by this method the usual observation was varying degrees of dilatation of the ducts in addition to definite cysts.

In the six cases of adenofibroma the chief effect of the tumor was displacement and compression of the ducts. Case 20 (H. Y., a Negress aged 18) is typical and is also a particularly good one in which to emphasize the importance of taking both lateral and vertical views. The lateral view, which showed a filling of the finest radicles in the upper half of the breast and a widening of the duct pattern, with incomplete filling in the midportion, was contrasted with the vertical view, which showed, in addition to incomplete filling, a definite compression and displacement of the ducts toward the midline.

The four cases in which laboratory examination of the amputated breast revealed a reaction to the injected substance are reported herewith:

CASE 6.—M. L., a Negress aged 20, complained of a firm, irregular, movable mass, 2 cm. in diameter, in the upper inner quadrant of the left breast, which had been present for a year. There were two similar but smaller masses in the inner middle third of the same breast. The clinical and radiographic diagnosis was cystic disease, which was confirmed by the laboratory examination following biopsy six days after the injection. Microscopic examination also revealed an early foreign body reaction in the periductal tissue, in which could be seen many leukocytes and many phagocytic cells containing particles of thorium dioxide (fig. 2).

CASE 1.—B. F., a white woman aged 57, was previously mentioned as having a malignant growth in the left breast, associated with intraductal papillomas, which was diagnosed clinically but was not revealed by mammography. The right breast, which was of the "shotty" type, had been injected at the same time as the left (fig. 3 A), and the patient was advised to submit to amputation within six weeks. She returned within a month, however, because of a mass the size of a hen's egg, which had developed in the lower inner quadrant of this breast. The mass was firm but not fixed. A similar lump, as large as a pigeon's egg, could be palpated in the upper outer quadrant. The breast was not painful or tender, and no glands could be palpated in the axilla. Carcinoma was suspected, and radical mastectomy was performed. The laboratory examination, however, revealed, instead of the suspected malignant condition, a marked foreign body reaction (fig. 3 B), which entirely

Fig. 4 (case 7).—Cystic disease and intracystic papillomas.

explained the clinical picture. There were large areas of necrosis, and under the microscope many phagocytic cells were seen which contained granules of thorium dioxide.

CASE 7.—A. B., a Negress aged 60, complained of painful, pendulous breasts which contained small, rather indefinite nodular masses throughout their substance. The radiographic diagnosis of cystic disease and intracystic papillomas (fig. 4 A and B) was confirmed in the laboratory after amputation of the breast, which had to be deferred for a month until the patient's diabetes could be stabilized. The delay furnished the opportunity for some interesting observations. Soreness promptly developed in both breasts following the injection of the

stabilized colloidal thorium dioxide. In the left breast it subsided promptly. In the right breast it was associated with an edema which persisted for ten days and with the development of a mass in the upper half. This mass grew rapidly, and gross examination after the breast had been amputated was strongly suggestive of carcinoma. Microscopic study, however, showed in addition to the cystic disease and intracystic papillomas already mentioned a marked foreign body reaction (fig. 5) of the type described in case 1. This reaction fully explained the masses which developed after the injection.

CASE 11.—L. G., a Negress aged 32, discovered a mass in the midportion of the right breast, beneath the areola, shortly before her admission. The mass, which was 4 cm. in diameter, was painful but not fixed. A thin, watery secretion could be expressed from both nipples. Two ducts of the affected quadrant were injected with iodized oil, and simple mammeotomy was done three days later. Laboratory examination confirmed the clinical and radiographic diagnosis of cystic disease and revealed also an early irritant reaction, evidenced chiefly by small areas of necrosis and by the presence of many leukocytes in the periductal tissue. Both in this tissue and within the lumen of the ducts, large vacuolated phagocytes could be seen.

COMMENT

These four cases are well worth putting on record, for only three similar reports seem to have appeared in the literature. Ries in 1930 reported an abscess of the breast which required amputation and which developed following the injection of iodized oil into the mammary ducts six weeks after lactation had ceased. Hicken, as we have noted, reported an abscess of the breast following the injection of colloidal thorium dioxide into a breast which was already the site of an acute infection. Sowers and Masson⁴ from the Mayo Clinic reported a case of extensive fat necrosis which required mammeotomy following the injection of colloidal thorium dioxide into a breast which was the site of a chronic mastitis. The necrosis in this case and the presence of

Fig. 5 (case 7).—Foreign body reaction (marked) caused by the injection of an opaque substance.

cells containing granules of thorium suggest precisely the same type of reaction that were encountered in the cases herein reported.

As soon as we realized the reaction likely to follow the use of opaque mediums in mamnography, we under-

4. Sowers, B. F., and Masson, J. C.: Mastitis Following Use of Thorium Dioxide. Report of Case, Proc. Staff Meet., Mayo Clin. 12: 529-531 (Aug.) 1937.

took a series of experiments in which we injected twenty-eight breasts in four dogs, using the same technic which we had employed in our clinical cases. The results are summarized in the accompanying table. One or two ducts were injected in each breast. Roentgeno-

Fig. 6.—Experimental studies of ducts injected with various substances immediately after the injection and immediately after an attempt to remove the injected substances by lavage. A and D colloidal thorium dioxide; B and E, iodized poppy-seed oil; C and F, chloriodized poppy-seed oil-Lilly.

grams were made immediately after the injection, to make certain that there had been no extravasation of the injected material into the tissues, and were repeated before the breasts were amputated, which was done from ten to eighty days later.

Of the various opaque mediums used in our experimental work, stabilized colloidal thorium dioxide, iodized oil and chloriodized oil furnished easily the most satisfactory pictures. Hippuran, diodrast, sodium iodide and soluble iodophthalein were not of sufficient density to cast satisfactory shadows. Chloriodized poppy-seed oil (theridol Lilly) was more satisfactory than the last group of substances but not as satisfactory as the first. Iodized oil was open to the same objection as in our clinical work—that its viscosity made it difficult to inject.

It will be noted from the tabulation of experimental results that in twelve of the twenty-one breasts amputated after injection an inflammatory reaction of the foreign body type was noted, all but two of which were severe. Furthermore, the reactions to colloidal thorium dioxide and to iodized oil were of precisely the same type as had been noted in our clinical cases. The early or mild reaction to colloidal thorium dioxide was manifested by a periductal infiltration of leukocytes and of large phagocytic cells filled with refractile granules of the injected substance. The later or advanced reaction took the form of necrosis. Phagocytic cells filled with thorium dioxide were also present, as in the early reaction, and giant cells were found in some areas.

The reactions to iodized oil, chloriodized poppy-seed oil-Lilly and chloriodized oil were similar. The early or mild reactions were a periductal inflammation, polymorphonuclear cells and large vacuolated phagocytes being seen throughout the affected tissues. Actual necrosis was present in the more advanced reactions.

Hicken has suggested that after the x-ray studies are made the injected substance be removed from the

breast by lavage or by milking the ducts with a breast pump. We did not employ either of these methods clinically, but in four experimental breasts we did employ lavage, using 20 cc. of saline solution. The x-ray studies were repeated as soon as the lavage was completed. The shadows cast by the iodized oil and chloriodized poppy-seed oil-Lilly were practically unchanged, but it seemed to us that most of the thorium dioxide

with iodized oil, colloidal thorium dioxide and chloriodized oil a week before its puppies were born. After the puppies had nursed for a month and the breasts had thus been subjected to a physiologic lavage far more perfect than could ever be achieved by mechanical

Fig. 8.—Demonstration of the lobes of a (right) breast by the injection of the ducts with materials of various colors, after which the tissues were removed by the use of corrosive agents. No communication is evident between the lobes. Note the apparent unevenness of distribution of the ducts, which is due to the fact that the ducts of the lower lobes, because of the dependent position of the breast, are turned under and so appear heaped up, while the ducts of the upper lobes slant downward. (Specimen prepared by Dr. D. D. Baker.)

had been washed out (fig. 6). Yet when this breast was amputated ten days afterward precisely the same type of foreign body reaction was noted as had been noted in the breasts in which lavage had not been prac-

Fig. 7.—Studies of the breasts of a pregnant dog injected with various opaque substances seven days before delivery and after the animal had nursed the puppies for thirty days. A and B, colloidal thorium dioxide; C and D, iodized poppy-seed oil; E and F, chloriodized oil.

ticed. There was no reaction in the breasts that had been injected with iodized oil and chloriodized poppy-seed oil-Lilly and later emptied by lavage.

Even more convincing was the observation of an experimental animal the breasts of which were injected

measures, the x-ray examination was repeated. The shadows cast by the injected substances were less dense than on the first examination, it is true, but they were still perfectly definite (fig. 7), which seems to prove the impossibility of complete removal of the injected matter by milking or lavage.

In one of our clinical cases (6) repeated roentgenograms at the end of six months showed the colloidal thorium dioxide still present in the ducts, and the same phenomenon was noted in other cases observed for shorter periods. It is significant that in the case reported by Ries in 1930, which was the first reported instance both of mammography and of the reaction which may follow it, examination at the end of six months showed the iodized oil still in situ.

The use of opaque mediums as an aid in the diagnosis of diseases of the breast cannot, in our opinion, ever be anything more than a diagnostic aid. In the hands of men like Hicken and his associates, who have perfected themselves in the interpretation of the films taken by this method, it seems to be reliable, but its casual and occasional use is likely to be misleading and dangerous. That is clearly proved by the two cases in our own small series in which it failed to reveal a malignant growth which was present and which clinically was clearcut. We doubt, furthermore, whether even in expert hands the method will ever be sufficiently positive to warrant the omission of biopsy in any case in which the diagnosis is not so obvious that diagnostic section is clearly unnecessary.

The basis of the method lies in changes in the outline of the ducts, whether by extrinsic or by intrinsic pressure. But when a malignant tumor has begun to encroach on the ductal lumen the disease is likely to

be so far advanced that diagnostic aid is frequently not needed and mammography not indicated. The ductal system of the breast possesses no motility, for one thing, and for another it is very complicated (fig. 8). Large defects are not likely to be overlooked, but smaller defects, because of superimposed shadows, may be difficult or impossible to demonstrate. For this reason, if the method is relied on absolutely it may give rise to a totally unwarranted sense of security.

We have no wish at this time to prophesy what the ultimate usefulness of this method may be. We are not inclined to dismiss it, as Masson has done, with the statement that it is "merely another attempt at mechanical diagnosis." On the other hand, we do feel very strongly, in the light of our own experiences, that it is likely to give rise to false impressions and that its use is not justified until some opaque agent is discovered which is satisfactory from the radiologic standpoint and yet not irritating to the breast tissues. Such an agent is apparently not now available.

The outstanding feature of the study which we have conducted is that reactions occur from the injection of opaque mediums with far greater frequency than the literature would suggest. In our small series of twenty-five cases there were four reactions, three of which were very severe; in two cases (1 and 7) amputation would certainly have been required because of the reaction if it had not already been planned for other conditions. We have no doubt too that, if operation had been longer delayed in the other cases, more reactions would have been apparent; it is significant that the most marked reactions we observed occurred in the cases in which operation had been longest delayed. Furthermore, more than 50 per cent of our experimental injections were followed by reactions precisely similar to those which we had observed clinically.

Since it is impossible to predict in which cases reactions will occur, and since the method apparently adds little or nothing to what clinical observation can supply, we ourselves have discontinued its clinical use and we would advise those who are planning to employ it, before they accept it unreservedly, to check their results with such laboratory investigations as we have undertaken. Ries really summarized the whole matter when he wrote in reporting the reaction following the injection of iodized oil observed by him: "While the demonstration of the size and shape of the milk ducts by lipiodol was perfect, the sequelae would suggest considerable caution in the application of the procedure."

SUMMARY

1. Reports in the literature of the value of mammography and of the harmlessness of stabilized colloidal thorium dioxide under these circumstances led us to undertake its use in a personal investigation. The material includes twenty-five cases, twenty-three of which were surgical.

2. In thirteen of the twenty-three cases the mammographic diagnosis agreed with the clinical diagnosis and was later confirmed in the laboratory. In other cases, however, the diagnosis was either not clear or actually incorrect; the most serious of these errors occurred in cases of malignant conditions which were evident clinically but which were not revealed by x-ray examination after injection of an opaque agent.

3. In four of the twenty-five clinical cases the injection of iodized oil or of colloidal thorium dioxide gave rise to foreign body reactions, three of which were very severe; in two of these three cases amputation would have been necessary because of the reaction if it had

not already been planned for another condition. Only three similar cases, all by different authors, have been reported in the literature.

4. An experimental study resulted in more than 50 per cent of foreign body reactions, all of which were similar to the reactions noted in clinical cases. The various agents used experimentally, all of which were satisfactory from the radiologic standpoint, were sometimes followed by reactions. Lavage of the breast after injection did not prevent the reaction in all cases, nor did the physiologic lavage brought about by the act of nursing.

5. We do not feel that the method, as it is now employed, contributes diagnostic aid of sufficient value to warrant the risks of the serious reactions that may follow it. Until an agent is discovered which is non-irritating to the breast tissues and which is at the same time satisfactory from the radiologic aspect, we do not advise the use of mammography by means of contrast mediums.

MULTIPLE PERIPHERAL NEUROPATHY VERSUS MULTIPLE NEURITIS

I. S. WECHSLER, M.D.

NEW YORK

In his "Classic Description of Disease,"¹ Ralph Major quotes a Greek poet of the second century B. C., named Nikander, who described as the harmful *cerusa* what seems to have been lead palsy. It is quite probable, as Singer pointed out, that Hippocrates was the first to give a clinical description² of diphtheritic paralysis, although he was obviously unaware of the concept. Actually it was not until 1616 that François Citois of Poitiers recognizably described lead colic with peripheral paralysis. In a paper published in 1772, though written five years earlier, Sir George Baker³ practically demonstrated that Devonshire colic was due to lead. Jacob Botins wrote of beriberi in 1642, evidently a posthumous paper, as he died in 1631, and Nicholas Tulip described beriberi *indorum* in 1716.

Gaspar Casal recognized pellagra in 1735, though his paper was not published until 1762. It was John Coakley Lettsom,⁴ however, who originally described alcoholic multiple neuritis. James Jackson⁵ of Boston reported cases of alcoholic polyneuritis from the Massachusetts General Hospital under the title of "arthrodynia à potu," as early as 1822. So far there were merely clinical descriptions, and it was as late as 1864 that Dumenil⁶ reported on the pathologic examination of peripheral nerves in cases of multiple neuritis. The pathologic studies of Lancereaux (1871), Gombault (1873) and Joffroy (1879)⁷ finally led to the establishment of the whole concept.

From this meager historical sketch it is evident that clinical descriptions of multiple neuritis are very old, and even the concept itself is now venerable. Indeed it has come to be accepted almost as an axiom which

is not to be questioned; so that it would appear rather presumptuous to inquire into its validity. None the less a number of doubts have arisen in recent years to warrant reexamination of the whole subject. 'It

tiple neuritis be retained only in the rare instances in which there is demonstrable inflammation of nerves.

Before validating the conclusions and justifying the change of concepts, it may be of interest to recall how the question came to be raised. At first general doubts arose as to the true cause in cases of polyneuritis or multiple neuritis of obscure origin; that is, in the not infrequent instances in which a specific causative factor could not be found despite diligent search. In such cases recourse was generally had to the words toxic or infectious. What was specifically toxic or infectious, when neither condition was demonstrable, was never stated. It was pointed out, therefore, that the glib tendency hitherto indulged in to invoke those explanations was highly unsatisfactory and that the "nonspecific" use of either term merely served to cover ignorance and really explained nothing at all.⁹ Based on clinical evidence and theoretical considerations, the conclusion was reached that in those obscure cases in which

Fig. 1.—Sciatic nerve from a patient with carcinoma of the stomach, showing neuropathy due to avitaminosis. Note the degeneration of the myelin sheath. (From the Department of Neuropathology, the Montefiore Hospital.)

seems to me that the evidence which has gradually and almost imperceptibly accumulated not only confirms those doubts but raises anew the question whether in the majority of cases of what is commonly known as multiple neuritis the concept is at all true. As a matter of fact there is much clinical and experimental evidence to show that what passes for neuritis is not an inflammatory process, and, so far as this is true, the term multiple neuritis is not only erroneous but misleading as well. It may also be stated with assurance that the pathologic changes demonstrated in most of the cases hitherto regarded as inflammatory are actually degenerative.

It becomes necessary, therefore, not only to discard what should now be recognized as a misnomer but to revise practically the whole subject of multiple neuritis. Not that there are not cases in which there is inflammation of peripheral nerves, that is, true multiple neuritis; but these form a group by themselves and a comparatively small one at that. I have therefore suggested⁸ that the designation multiple neuropathy be adopted and used in the vast majority of cases in which degeneration of peripheral nerves is the underlying pathologic change and the old term mul-

none of the various factors hitherto regarded as the causes of multiple neuritis could be found, the condition was due to food deficiency. From the clinical

point of view the condition could not be classified either as beriberi or pellagra, although these two diseases were naturally suspected. Indeed, Shattuck¹⁰ had previously suggested the relation of beriberi

to polyneuritis, without however, describing case material.¹¹

Further observation and more extensive study¹² led to the question of whether, even in cases in which alcohol, arsenic or diabetes is presumed to cause neuritis, a deficiency factor is not the ultimate cause. Finally, experimental work on monkeys intoxicated with alcohol and deprived of vitamins¹³ gave further proof of the two contentions; namely, that what passes for neuritis is a neuropathy and that what passes for an ultimate cause, in this case alcohol, is but one factor, with avitaminosis another in the causation of "multiple neuritis." Subsequently Minot, Strauss and Cobb¹⁴ then Strauss¹⁵ and, more recently, Jolliffe, Colbert and Joffe¹⁶ brought almost absolute proof of the relationship of avitaminosis to alcoholic polyneuritis. The formula worked out by Cowgill,¹⁷ that is, the vitamin-caloric ratio, furnished a more precise and scientific basis for the study of the whole subject.

Fig. 3.—Sciatic nerve from a patient with multiple "neuritis." The neuropathy was of undetermined origin. (From the Department of Neuropathology, the Montefiore Hospital.)

As to pathology, one could justly conclude on theoretical grounds alone that the changes in "neuritis" from the effects of alcohol, lead, carbon monoxide or diabetes, for instance, are not inflammatory in nature. To begin with, the neuron, and indeed all nerve tissue, being ectodermal in origin, does not easily react with an inflammatory reaction (except in poliomyelitis and some forms of encephalitis). Mesodermal structures, that is, connective tissue and blood vessels, do so react. It is the coverings of the brain and spinal cord and of the peripheral nerves that show inflammatory reactions. The nerve fibers show degeneration. Secondly, it is not likely that a substance which causes

degenerative destruction of the brain or spinal cord will bring about inflammation of the peripheral nerves if it happens to affect them. It is known, for instance, that alcohol causes encephalopathy, and so does lead. Neither causes encephalitis. What passes for alcoholic polioencephalitis is not an encephalitis at all but an encephalopathy. The diphtheria toxin, like other specific toxins, causes degeneration and not inflammation of nerves.

Aside from theoretical consideration, however, it is necessary merely to examine photomicrographs of the pathologic processes of "multiple neuritis" (figs. 1, 2 and 3). They show destruction of myelin, fragmentation of axis cylinders and no round cell infiltration or inflammatory changes of an exudative nature. If the nerve cell is affected in the same process, there is no cloudy swelling and no neuronophagia, but just disappearance of the body and nucleus. In short, one sees only the changes of true degeneration. Carmichael and Stern,¹⁸ Sir Frederick Mott,¹⁹ Hassin,²⁰ Winkelman,²¹ Orton and Bender²² and others have amply proved this. It is of interest that the pathologic changes observed in most cases of "neuritis" are precisely the same as those associated with poisoning by heavy metals and vitamin deficiency. In the latter conditions there never is any question of inflammation. The fact is that the old descriptions of "neuritis" date to the days when histologic methods were less refined and the concepts less precisely defined.

Still other evidence points to the validity of the concept of neuropathy as against that of neuritis. If it is true that in many cases of so-called multiple neuritis there is food privation and therefore avitaminosis, there is every reason to expect a degenerative process, such as is seen, for instance, in spinal cord and root lesions of pernicious anemia. Such a process is precisely what occurs; the peripheral nerves, however, are more selectively its seat, although the spinal cord does not escape in many cases of peripheral neuropathy. Indeed in some instances, particularly of poisoning by alcohol, lead or carbon monoxide, the brain too suffers. It may be repeated once more that in these cases one is dealing with an encephalopathy and not an encephalitis. It is also of interest that in practically all of the cases of so-called multiple neuritis in which I had occasion to examine the gastric contents there were absence of free hydrochloric acid and either complete absence or marked reduction of the total acidity. In cases of what is known as pregnancy polyneuritis, not only is there invariably a history of persistent vomiting and hence starvation but, in many cases, there is an

encephalopathy which manifests itself as an organic psychosis of the Korsakoff type. The conclusion is justified that the same degenerative process in the brain affects the peripheral nerves and leads to multiple neuropathy.

The acceptance of the term multiple neuropathy will merely round out terminology and make it conform with the accepted terminology as it applies to the brain and spinal cord. Just as the term encephalopathy is used for degenerative changes in the brain, whether toxic or vascular, and the term encephalitis is reserved for inflammation of the brain, and just as the concept of myelopathy has been accepted for degenerative lesions of the spinal cord and the term myelitis has been limited to inflammatory changes within the cord, so multiple neuropathy could be used for degenerative changes in the peripheral nerves, the old term polyneuritis being restricted to those much rarer conditions in which there is actual inflammation of nerves. (The term neuronitis, which has been suggested, is unacceptable for the same reasons that neuritis is, and the word neuronopathy, which is possibly more correct etymologically, is rather cumbersome and not quite euphonious.)

That there are cases of multiple neuritis on the basis of inflammation admits, of course, of no doubt. But there is always clinical evidence of infection in those cases. They are often characterized by fever and its concomitants. The spinal fluid is apt to show signs of inflammation, namely, an increase of globulin, protein and cells. The disease syndrome runs a more rapid, often a more severe and not infrequently a fatal course. Involvement of the cerebral nerves, especially of the facial nerves on both sides, points to cerebral and meningeal disease. Finally, the inflammation is possibly related to virus diseases and may accompany influenza and the exanthems. But, what is perhaps more important, certain cases of epidemic encephalitis are actually characterized by syndromes of multiple neuritis.

My suggestion therefore is that the terms alcoholic multiple neuropathy, lead neuropathy, diphtheritic neuropathy and so on be used henceforth. This is not mere caviling at words. The change in nomenclature is important because it embodies a different concept and fits an actual pathologic condition. Even scientific tradition does not justify the perpetuation of a misnomer. The newer concept is valuable and important because it serves as a guide to treatment, both preventive and curative. It is obvious that the treatment of degenerative diseases differs from that of inflammatory states. One does not have to seek for nonexistent sources or foci of infection and extract teeth or tonsils, for example. More emphasis, in addition to the removal of sources of foreign noxious substances, can be put on dietary treatments. When, in the future, more knowledge is accumulated as to selective affinity and nerve specificity of vitamins, logic will be better served if the fact is borne in mind that the condition is a neuropathy and not a neuritis.

CONCLUSIONS

1. The whole concept of multiple neuritis is in need of revision, and the very term as used in most of the cases now so designated is a misnomer.

2. In the vast majority of cases, whether the condition is due to a toxin, foreign poison or avitaminosis, there is a degenerative and not an inflammatory process.

3. It is suggested that the term multiple neuropathy, polyneuropathy or peripheral neuropathy be substituted for multiple neuritis in those cases in which both the cause and the pathologic changes point to a degenerative process, and that the designation neuritis be retained only in those cases in which there is adequate causation and in which an inflammatory condition is recognized as well as demonstrable.

4. The nomenclature will then conform to that now employed in the case of the brain and spinal cord, namely neuropathy, encephalopathy and myelopathy.

Clinical Notes, Suggestions and New Instruments

BISEPTATE UTERUS

ADENOCARCINOMA IN ONE UTERINE CAVITY AND A PEDUNCULATED POLYP IN THE OTHER

HAROLD J. SHELLEY, M.D., NEW YORK
Assistant Attending Surgeon and Chief of Surgical Clinic,
St. Luke's Hospital

Neither biseptate uterus nor adenocarcinoma of the body of the uterus is particularly rare, but a combination of these two conditions together with a pedunculated polyp in the other uterine cavity is a sufficiently unusual condition to justify its being reported. Another reason for reporting this case is to emphasize the necessity for a thorough exploration of the uterine cavity in women who bleed after the menopause, even though the first curettings should reveal a uterine polyp.

REPORT OF CASE

History.—A woman, aged 58, a housewife, seen in the office Nov. 11, 1936, gave a history of having passed through a normal menopause with cessation of menstruation five years previously. Six months before the time of her examination she had first

Fig. 1.—The uterus as it appeared from the outside. The depression at the fundus can be seen. The tubes, ovaries and broad ligaments are not remarkable.

noticed a slight watery vaginal discharge. Four months later this became more profuse, and for the last six weeks it had been definitely bloody. At no time had there been any pain or other symptoms. She had not lost weight. She had never been pregnant.

The patient was in excellent physical condition. Examination was entirely negative except for the bloody vaginal discharge, which was found to be coming from the uterus. Pelvic examination showed the uterus normal in size and position. There was no tenderness nor were there palpable masses in either fornix.

From the Surgical Service, St. Luke's Hospital.

November 12, with the use of cyclopropane and ether anesthesia, the cervix was dilated and some rather large pieces of tissue were removed from the uterine cavity with a sharp curet. Frozen sections showed this to be an adenocarcinoma of the body of the uterus. A lower midline incision was then made. A panhysterectomy, bilateral salpingo-oophorectomy and complete removal of the broad ligaments and the adjacent gland-bearing areas were done. Closure was made in layers without drainage after complete peritonealization had been carried out.

Fig. 2.—The appearance of the uterus when it was opened. The fibrous septum divides the uterine cavity into two parts as far down as the internal os. In the right side is a pedunculated polyp which was 3 cm. long. In the left side is a fungating tumor which on section proved to be an adenocarcinoma of the body.

Convalescence was uneventful. She was discharged from the hospital on the eighteenth postoperative day with a firm, well healed scar.

Pathologic Examination.—The specimen consisted of uterine curettings, the uterus with the cervix, both tubes and ovaries and the broad ligaments.

There were several pieces of curetted tissue, which was friable and a reddish gray. The uterus measured 7 by 7 by 3 cm. There was a definite depression at the fundus. When it was opened a fibrous septum was seen to divide the uterine cavity into two compartments, as far as the internal os. In the right side was a pedunculated polyp measuring 3 by 1 by 1 cm. On the left side was a fungating tumor which completely filled the cavity. The cervix appeared grossly normal. Both tubes and ovaries appeared grossly normal. In the left broad ligament was a firm white nodule 0.5 cm. in diameter.

Microscopic examination of the fungating tumor and curettings showed a papillary growth, much of which was adenomatous, but other portions had become more anaplastic and irregular; the nuclei were large and hyperchromatic, and the glands showed atypical branching, so that the mass could only be considered already malignant. The attachments of this tumor showed it invading the uterine muscle rather superficially but with well developed glandular acini and a more papillary structure. The uterine muscle beyond this was relatively normal.

The left ovary was fibrous and atrophic.

The right ovary contained numerous glandular rests with low columnar, relatively undifferentiated lining cells. Some of these were small, while others were larger and were cystic. They did not differ from those often seen in the ovary, except in their number.

The tubes showed small central lumens with atrophic mucosa.

The nodule from the left broad ligament showed a small central cavity lined with undifferentiated low columnar epithelial cells and surrounded by bundles of smooth muscle. This might represent the canal of Nuck.

The diagnosis was biseptate uterus; adenocarcinoma of the uterine cavity, on the left; pedunculated polyp of the uterine cavity, on the right; atrophic tubes and ovaries.

Follow-Up.—When last seen one year after the operation the patient was symptom free, and pelvic examination was negative except for the absence of the cervix.

COMMENT

In a case of biseptate uterus, an adenocarcinoma of the body of the uterus was found in the left cavity and a pedunculated polyp in the right. At the time the diagnostic curettage was done, had the curet gone into the right cavity instead of the left the uterine polyp would have been removed and might well have been considered to be the sole cause of the bleeding. Had this happened, the opportunity for early removal of the adenocarcinoma of the uterus might have been lost, unless there was considerable continued bleeding after discharge from the hospital. When the pieces of adenocarcinoma were obtained with the curet, no additional curetting was done. Had the polyp been removed first, of course, a thorough curettage would have followed. But it is possible to see how the curet might have gone into only one cavity of the uterus.

CAVERNOUS HEMANGIOMAS OF THE LUNG WITH SECONDARY POLYCYTHEMIA

C. B. RODES, M.D., BUTTE, MONT.

A recent review of the literature on hemangioma of the lung has impressed me sufficiently to indicate that the report of such an observed case complicated by secondary polycythemia is warranted; more so because a record of such a complication as hemangioma of the lung in any type of polycythemia could not be found. Several reports, however, of malignant types of hemangiomas of the lung and pleura were found, as well as those of both benign and malignant lesions of other viscera.

De Lange and de Vries Robles¹ and Bowers² reported cases of the benign type in the lungs of infants. To further the interest, Hirsch³ recently published an article on pulmonary changes in polycythemia vera.

Roentgenograms taken in the case here reported showed shadows similar to those demonstrated in Hirsch's cases. He consented to compare the roentgenograms taken in this case with those taken in his reported cases, stating "I find the nodules, particularly those of the left lung, similar in appearance to those I have described."

REPORT OF CASE

B. C., a white man, aged 25, an American, was first seen by me Dec. 10, 1935.

The family history was as follows: The father died at the age of 50 of cancer of the sigmoid and colon. The mother and one brother are living and well. One sister died in infancy.

The patient had had measles, mumps, whooping cough, chickenpox, smallpox and tonsillitis. He had a tonsillectomy

Appearance of chest showing shadow of nodules in middle portion of lower lobe of left lung.

2. Bowers, W. E.: *Rupture of Visceral Hemangioma as Cause of Death*, *Nebraska M. J.* 21: 55 (Feb.) 1936.
3. Hirsch, I. S.: *Pulmonary Changes in Polycythemia Vera*, *Radiology* 26: 469-473 (April) 1936.

when he was 10. There was some shortness of breath as long as could be remembered. The lips and hands were always bluish. Slight clubbing of the fingers was noticed at about the age of 15 and of the toes two years before admission. He had epileptiform seizures, six in all, during the age period of 16 years and gonorrhea one year before the present trouble.

The present complaint started about one month before I saw him. At that time he noticed that the urine was dark and that the skin and whites of the eyes seemed slightly yellow. He consulted his family physician, who suggested that the liver or kidneys were not functioning. There was no pain. He thought that he was getting somewhat shorter of breath and that the lips and finger nails were more purplish.

On physical examination the patient was fairly well developed and nourished. He was 6 feet (183 cm.) tall and weighed 150 pounds (68 Kg.) nude. The lips were dark, almost purplish, with several very small bluish spots on each having the appearance of hemangiomas. The head, face and neck were normal. The heart was not enlarged; there were no murmurs. The lungs were apparently clear. Examination of the abdomen was negative on palpation. There was marked clubbing of the tips of the fingers and toes. Neurologic examination revealed normal reflexes; motor and sensory studies were essentially negative throughout. The pulse rate of both radial arteries was 80. The blood pressure in both arms was 130 systolic, 75 diastolic.

The blood count December 12 was hemoglobin 118 per cent, red blood cells 7,540,000, white blood cells 9,800, neutrophils 52 per cent and lymphocytes 48 per cent. The urine was clear, straw colored and acid, with a specific gravity of 1.021, albumin 0, sugar 0, red blood cells 0 and white blood cells 0.

A roentgenogram taken at this time is here reproduced.

The patient returned December 27 for a recheck. Physical examination showed no changes. The blood count was hemoglobin 108 per cent, red blood cells 7,180,000, white blood cells 10,700, neutrophils 62 per cent, lymphocytes 38 per cent. Roentgenograms corresponded to those previously taken.

The history given by the mother post mortem revealed that the patient never felt better in his life when on Thursday, May 20, 1936, at 5 p. m., he was suddenly seized by severe pain below the sternum and in the upper part of the abdomen, followed immediately by hemorrhage from the lungs. She was unable to estimate the quantity of blood but said that there was a considerable amount. He recovered nicely following this hemorrhage. Again on Sunday, May 24, at about the same hour, he coughed up another slight quantity of bright blood. The following Tuesday night at 10:15, after having eaten a heavy meal and taken an automobile ride, he was stricken by a sudden fatal hemorrhage, death being almost immediate.

AUTOPSY

The body was well developed. There was marked clubbing of the tips of the fingers and moderate clubbing of the toes.

The body was embalmed through the right inguinal vessels and there were abdominal trocar punctures.

Nothing unusual was found in the abdominal cavity, the organs being of normal size, weight and appearance. The thoracic and pleural cavities were normal except for bloody fluid apparently introduced by the embalming trocar. The thoracic viscera were removed in toto for examination.

The heart measured 12 cm. transversely and 10 cm. vertically and lay normally in the pericardial sac. It weighed 350 Gm. The musculature was of normal thickness and appearance. The coronary arteries were patent. The mitral valve was moderately thickened and slightly roughened but the other valves were grossly normal. The root of the aorta showed a few yellow atheromatous plaques but was neither dilated nor distorted.

The bronchi were opened from the posterior aspect. The left bronchus showed a moderate amount and the right was completely filled with clotted blood. The lower anterior margin of the right lung showed a dark blue saccular mass 2 cm. in diameter. A similar mass, 6 cm. in diameter, was found in the posterior portion of the right median lobe. There was a similar mass measuring 6 by 3 by 2 cm. in the midportion of the upper lobe of the left lung. On section these masses were

filled with blood and were multilocular, the lining being smooth and thin. Rupture into the bronchi was not found.

The posterior and inferior portions of the lung were diffusely congested with dark hemorrhagic and slightly foamy fluid. Microscopically the masses in the lung showed endothelium-lined cavities filled with blood. Nothing notable was found in the microscopic sections of the other organs.

The diagnosis was multiple hemangioma of the lung, with rupture into the bronchus.

Motor Clinic Building.

GLAUCOMA

PRELIMINARY REPORT OF AN OPERATIVE PROCEDURE

OTTO BARKAN, M.D., SAN FRANCISCO

The following is the preliminary report of a surgical procedure for primary chronic glaucoma of the shallow chamber type:

According to recent microgonioscopic and surgical investigations¹ primary glaucoma may, with few exceptions, be divided into two main anatomic types according to the mechanical cause of the increased intra-ocular pressure. One type is characterized by normal or deep chamber and open iridic angle. In this the increased pressure is caused by blockage of the sclerocorneal trabeculum, and a rational operation, "goniotomy," has been suggested for its relief.² The second type is characterized by a shallow chamber and is produced by obstruction of the filtration angle by the root of the iris. An operative procedure for its relief is presented herewith. This procedure may be employed as an early or prophylactic operation or it may be employed, with safety and without complicating sequelae, for the relief of those cases in which there is a high degree of intra-ocular tension and which threaten to run a malignant course.

The object of the procedure is to reduce increased intra-ocular pressure in a rational and safe manner by means of correcting the mechanical obstruction which is the causal factor. It consists of performing one or more excisions of the root of the iris in such manner that the anterior chamber is maintained and post-operative adhesions of the iris in the angle are prevented. The technic combines (1) preliminary aspiration of vitreous, (2) deepening of the anterior chamber by means of injection of physiologic solution of sodium chloride before, during and immediately after the operation, (3) making one or more successive oblique valvelike keratome incisions within the corneal tissue near the limbus and (4) excision of one or several pieces of the root of the iris.

The purpose of the operation is to reduce and prevent increased intra-ocular pressure in the shallow chamber (narrow angle) type of glaucoma.

Postoperative examination of the iridic angle reveals the result of the procedure to be equalization of pressure in front of and behind the iris, posterior displacement of the diaphragm of the iris within the region of operation, deepening of the chamber with widening of the angle and subsequent increased access of aqueous to the filtration angle.

The procedure appears to solve the technical difficulties and avoids the dangers commonly associated with operations in this type of glaucoma. It restores and maintains the physiologic direction of outflow of aqueous. There is no appreciable refractive error produced and there is no cosmetic disfigurement. The sphincter of the pupil is preserved. It avoids the danger of running a malignant course. It would appear to be free from the dangers of present day operations, such as iritis, late infection, cataract formation and other disturbing sequelae and complications. Judging from studies made in ten operative cases to date, the operation gives promise of answering adequately two great needs of glaucoma surgery in the shallow chamber type: (1) early safe operation and (2) prevention of a malignant course.

490 Post Street.

This procedure will be published in full in the Transactions of the American Medical Association after demonstration 16, 1938.

Therapeutics

THE THERAPY OF THE COOK COUNTY HOSPITAL

EDITED BY BERNARD FANTUS, M.D.

CHICAGO

NOTE.—In their elaboration, these articles are submitted to the members of the attending staff of the Cook County Hospital by the director of therapeutics, Dr. Bernard Fantus. The views expressed by various members are incorporated in the final draft for publication. The articles will be continued from time to time in these columns. When completed, the series will be published in book form.—Ed.

THE THERAPY OF GOITER AND OF HYPERTHYROIDISM

IN COLLABORATION WITH LINDON SEED, M.D.

The diagnostic characteristics of thyroid enlargement are that it follows the movements of deglutition and coughing. These are absent when the size of the mass is excessive or when there are adhesions.

It is important for therapy to distinguish between true goiter and (a) thyroid congestion, (b) inflammation or (c) a malignant condition.

(a) Thyroid congestion causes a moderate periodic, symmetric, smooth, painless enlargement of the gland during periods of stress, such as menstruation or pregnancy. It needs no treatment.

(b) Thyroid inflammation and acute suppurative thyroiditis are exceedingly uncommon. They set in suddenly after injury or during an infectious disease and have associated the signs of inflammation. The gland is hard and tender and there may be chills and fever, dyspnea, dysphagia and radiating pains. Abscesses may develop, which, when well localized, demand surgical drainage. Chronic woody thyroiditis, ligneous thyroiditis (Riedel's struma, Hashimoto's tumor) is somewhat more common. It may begin with tenderness over the thyroid, a slight fever and mild symptoms of hyperthyroidism. The thyroid is diffusely enlarged as a stony hard mass, moderately tender. In advanced stages a granulomatous infiltration may occur into the surrounding structures. It is difficult to distinguish from carcinoma. On microscopic examination there is a diffuse fibrous proliferation, wide destruction of acini, and round cell and even giant cell infiltration. In some cases resolution sets in, often leaving a thyroid deficiency. A subtotal thyroidectomy effects a cure but is likewise often followed by myxedema.

(c) Malignant goiter, usually carcinoma, is a stony hard, nodular, irregular swelling of the gland, usually first appearing in a patient over 35 years of age, which is very prone to produce pain, pressure symptoms, cachexia and metastases (especially to the lungs, skull, brain and bones). Early diagnosis and radical operation combined with x-rays or radium are the only hope.

True goiter must be differentiated from a therapeutic standpoint into four forms: nontoxic diffuse goiter, nontoxic nodular goiter, toxic nodular goiter and toxic diffuse goiter.

NONTOXIC DIFFUSE GOITER (SIMPLE, COLLOID GOITER)

Diagnosis.—A smooth, soft, symmetric enlargement in the lower part of the neck which rises on swallowing may be best examined by placing the fingers behind

the sternomastoid, the thumb over the isthmus, and asking the patient to swallow. Distress in the neck and pressure symptoms are uncommon. There is no pain on gentle manipulation, and generally no thrill or bruit, excepting possibly temporarily during menstruation or pregnancy. There are no constitutional symptoms. The basal metabolic rate is normal. In the large ones there may be evidence of hypothyroidism, i. e., bradycardia (from 62 to 40 beats per minute), intolerance to cold, disturbances in growth and menstruation, and a lowered basal metabolic rate. It usually appears in this country in girls at puberty as a small soft diffuse enlargement without symptoms. The majority of these disappear before 20, but some continue to enlarge and, as the years pass, develop into nodular goiters or may suddenly become toxic diffuse goiter.

Therapy.—Prophylaxis: In endemic areas, community use of iodized salt is best (1 mg. of iodide per kilogram of salt) or else a dose of 5 mg. of iodide once a week should be given, especially to girls between 11 and 16 years of age and during pregnancy. Sea food (from the sea but not from inland waters) is rich in iodine and is of prophylactic value. Much larger dosage of iodide may induce hyperthyroidism in those predisposed to it.

PRESCRIPTION 1.—Mild Iodide Medication

R Solution of potassium iodide..... 15.00 cc.
Three drops once daily for ten days, every six months in young children. In older children and adolescents slightly larger doses (from 4 to 5 drops) twice weekly.

PRESCRIPTION 2.—Mild Iodide Medication

R Syrup of hydriodic acid..... 15.00 cc.
Syrup of cherry..... to make 60.00 cc.
Teaspoonful in water once daily for two weeks, every three to six months.

PRESCRIPTION 3.—Mild Iodide Medication

R Syrup of ferrous iodide..... 60.00 cc.
Fifteen drops in water three times daily after meals.

PRESCRIPTION 4.—Thyroid

R 50 tablets of thyroid, each..... 0.06 Gm.
Once daily, the effect being carefully watched.

Treatment: (a) In endemic diffuse goiter the solution of potassium iodide (prescription 1) may be given in doses of five drops in milk twice a week or else the pleasant method of mild iodide administration be employed (prescriptions 2 and 3). (b) If small quantities of iodide continued for several months do not produce improvement, the administration of thyroid (prescription 4) is indicated. If no improvement occurs there is little else that can be done short of surgical removal. (c) In the sporadic form of long standing it is not safe to give iodide, as many of these goiters have adenomas hidden within them. They are best treated as though they were adenomatous goiter.

NONTOXIC NODULAR GOITER (THYROID ADENOMA WITHOUT HYPERTHYROIDISM)

Diagnosis.—This form is characterized by nodules appearing in the thyroid, causing asymmetric unsightly enlargement of the gland. Though nontoxic, it may become toxic at any time. Frequent basal metabolic tests may predict thyrotoxicosis even before symptoms are fully developed. If it grows outward in the neck, pressure symptoms are unlikely but the deformity is objectionable. Pressure symptoms occur if a nodule in one or both lobes becomes lodged behind the sternum or clavicle. Difficulty in breathing with an inspiratory

stridor is the chief symptom. The veins of the neck are distended; the appearance of hoarseness, recurrent laryngeal nerve paralysis and pain are indications of malignancy. Uncommonly the tumor is entirely intrathoracic and roentgenograms taken anteroposteriorly and laterally may be required to show the displacement and narrowing of the trachea.

Therapy.—Iodine must not be used; although it may diminish the size of the goiter, it never brings about a complete disappearance and may induce thyrotoxicosis, especially in patients past 50. Partial thyroidectomy is the only treatment. It is demanded when pressure symptoms occur or the tumor becomes unsightly. Indeed it is best to remove surgically all asymptomatic nodular goiters in persons past 40 years of age, for prophylaxis against hyperthyroidism or malignancy.

TOXIC NODULAR GOITER (THYROID ADENOMA WITH HYPERTHYROIDISM, PLUMMER'S DISEASE)

Diagnosis.—There is the usual history of a long latent period (from ten to twenty years) of nontoxic nodular goiter. Hence it is rare in persons under 25 years of age. Symptoms appear as an average at the age of 45 years. The onset is insidious and the course steadily progressive. Remissions and exacerbations are uncommon. Nervous phenomena are not marked. There are no crises. Circulation embarrassment may be the first complaint. There is an asymmetric enlargement of the thyroid without bruit or thrill. The mass may be intrathoracic and require roentgenographic demonstration. The symptoms of hyperthyroidism are present with the exception of the eye signs.

Therapy.—Iodide is contraindicated. Radiation therapy is unsatisfactory. Surgical removal of the adenoma usually gives prompt and permanent relief.

TOXIC DIFFUSE EXOPHTHALMIC GOITER (GRAVES' DISEASE, BASEDOW'S DISEASE, HYPERTHYROIDISM)

Diagnosis.—There is a history of goiter for a short time, rarely over a year. It is more common in young adults, very rare in children. The onset is rather acute and there is a tendency to remissions, exacerbations and crises. The following are the six cardinal symptom groups of exophthalmic goiter and of hyperthyroidism:

1. The thyroid enlargement is diffuse and has a firm, rather hard consistency. A bruit at the superior pole is present in 50 per cent of cases and is pathognomonic of toxicity. In 5 per cent of cases there is no palpable enlargement. It may be concealed. One must be on the lookout for "larval" or "masked" cases of hyperthyroidism, occurring in elderly patients. These are probably more common than is generally known.

2. The loss of weight and strength in the presence of a good appetite is most characteristic. It should lead one to examine the patient very closely for other symptoms of hyperthyroidism. The only other condition of which this syndrome is so characteristic is diabetes mellitus. The degree of weight loss is variable, but may be extreme, 30 pounds (13.6 Kg.) a month. The food intake is invariably increased. Loss of strength can easily be demonstrated in the performance of any single act of strength, as in stepping up on a chair.

3. There is persistent tachycardia associated with a normal or increased pulse pressure. The pulse is abnormally rapid (from 100 to 160 per minute) day in and day out. The systolic pressure has a tendency

to rise; the diastolic pressure drops and may even fade to zero. The average blood pressure readings are 150 systolic, 70 diastolic. A systolic blood pressure below 110 is rare. The circulatory rate is 50 per cent or more above normal. Cardiac dilatation and hypertrophy develop. Auricular fibrillation, often of a transient nature, occurs in half the cases beyond the age of 50 but is rare under 30.

4. Nervousness and tremor are present. The nervousness begins with the other symptoms and is of an objective character and is not what is called "inward nervousness." The patient moves rapidly, moves frequently, talks and even thinks rapidly. He is objectively overactive. Tremor is always present. This tremor cannot be arrested by pressure, as when the tips of the examiner's fingers are pressed against the finger tips of the patient.

5. Of eye signs the stare is the earliest and is evidenced by the showing of white sclerae between the upper lid and the iris (Dalrymple's sign). This appears more easily when the patient is subjected to stress and strain. The exophthalmos is usually symmetrically bilateral, but one eyeball may bulge more than the other. Von Graefe's sign is present when the eyeball is moved downward and the upper lid follows tardily or not at all, Moebius' sign when convergence is imperfect or lacking, Stellwag's sign when winking is infrequent and incomplete, with drying of the corneal epithelium and the formation of blood vessels on the cornea as the result of exposure, and Joffroy's sign when wrinkling of the forehead is absent when the eyes follow an object as far upward as they can rotate.

6. An increased basal metabolic rate is constant. A thyroidectomy is not indicated in cases suspected of hyperthyroidism in the presence of a normal basal metabolic rate. Because the first test in even a normal person may be high and because the factor of error is large, it is best to consider all readings up to plus 25 normal unless found repeatedly. The clinical evidences of increased heat production are important. There is intolerance to heat, increased tolerance to cold, flushing of the skin and a tendency to sweat. The hands and feet are never cold but warm and usually moist. The patient is very intolerant of oxygen deprivation and suffers from dyspnea on exertion.

Symptoms not constantly present are the following: Gastrointestinal symptoms, e. g., so-called colitis, usually due to the tremendously increased food intake. Diarrhea, especially in the crisis; two or three normal bowel movements a day are usual. The menstrual flow lessened or absent. Pruritus and pigmentation of the skin. Finger nail changes—the nail tends to leave its bed before reaching the end of the finger; it looks much as though injured by a sliver. Glycosuria is quite common (15 per cent) but is associated with a normal blood sugar. True diabetes is probably a little more frequent than in normal persons. Blood iodine is elevated in all cases. Blood cholesterol is diminished.

Crises are often set off by stress and strain, an infection, or an operation either on the thyroid or on some other organ; e. g., a tonsillectomy. The symptoms appear in the following order: sleeplessness, marked exaggeration of nervousness, anorexia, nausea and vomiting, sometimes diarrhea, high fever, delirium, jaundice, coma and death. The presence of marked mental disturbance is of serious import and in many cases presages death.

Therapy.—Prophylaxis: The appearance of the earliest signs of this condition should be watched for and treatment promptly instituted to prevent the development of vicious circles. This is done by lessening speed, stress and strain in those not fit to endure them. Predisposed persons must be given ample time to convalesce from any disease before returning to full duty. The thyroid hyperplasia liable to occur in children born to hyperthyroid mothers may be prevented by a month's mild treatment with iodide (e. g., syrup of hydriodic acid, prescription 3) during midgestation.

Treatment: (A) Surgery is the treatment of choice in fully developed cases, but it usually needs to be preceded and always followed by (B) suitable medical treatment. (C) Roentgen therapy should be reserved for cases unsuitable for surgical treatment or those who refuse operation.

A. Surgery requires (1) determination of operability, (2) preoperative preparation, (3) choice of proper surgical procedure, (4) postoperative care and (5) treatment of crisis, complications or sequelae.

1. The general rule for the determination of operability in a case of exophthalmic goiter is as follows: If the symptoms are improving, the patient will not die; if the symptoms are at a stationary level, it is unlikely that the patient will die; if the symptoms are growing progressively worse he is likely to die, and if he is in or approaching a crisis he will surely die if operated on. More specifically the following criteria are most important:

(a) If a patient has lost 40 pounds (18 Kg.) the past year but for the past six months has maintained a stationary weight, the risk is not great. If he has lost 20 pounds (9 Kg.) in the past two months the risk is not as good. If he has lost 10 pounds (4.5 Kg.) in the past month and still is losing, the risk is still worse. In fact, if he has lost only 3 pounds (1.4 Kg.) in the preceding week a thyroidectomy should not be done. Of course, a big weight loss is worse than a small weight loss; but a recent weight loss, even a small one, is worse than a large weight loss a year before. On the other hand, a recent gain in weight is very assuring. An accurate weight curve is more important than a series of tests to determine the basal metabolic rate.

(b) A patient who has retained his strength will tolerate a severe reaction; a feeble patient may die from a mild reaction. If the patient is able to be up and about most of the day and if he can walk round a block with reasonable ease, he has sufficient strength to carry him through a thyroidectomy. If he can step up on an ordinary chair his strength is good; if he needs a little help it is not bad; if he cannot step up on a low stool one should be very loath indeed about undertaking an operation.

(c) Nervousness is difficult to measure as to degree. A person who is easily upset, who on mild stress and strain becomes excited and tremulous, whose eyes stare wildly on little provocation and who is breathless on slight exertion will unquestionably have a sharp postoperative reaction. As calmness and tranquillity replace the restlessness and excitability, the risk measurably improves.

(d) The basal metabolic rate in itself is not so important as the effect of this rate on the patient. If the basal metabolic rate is under plus 50, the patient may be either a good or a poor risk; if it is over plus 60 it

is prudent to assume that he is a poor risk. A persistently dropping basal metabolic rate is of good prognostic significance.

(e) The average pulse rate in exophthalmic goiter is from 110 to 120; if it is persistently between 130 and 140 the risk is definitely increased. Auricular fibrillation is not serious. Decompensation as evidenced by edema of the legs or ascites must be remedied before operation. The ability to walk a block without undue dyspnea practically guarantees a heart that will carry the patient through a thyroidectomy.

(f) Other things that increase the dangers of operation are long duration of the symptoms, old age, evidence of other disease such as nephritis, toxic hepatitis or hypertension, severe myocardial damage, extreme youth and anatomic abnormalities.

2. Preoperative preparation consists of the administration of iodide, high food intake and partial rest.

(a) Any form of iodide is efficient. It is usually given as Compound Solution of Iodine (Lugol's solution) in doses of 0.7 cc. in milk or grape juice three times daily after meals. But giving iodide, in the form of Solution of Potassium Iodide (prescription 1), is probably better technic, because the local effect of iodine is not desired. The exact dosage is not known. Small amounts seem as effective as larger quantities; hence the latter are not indicated.

(b) A high food intake is imperative. This can be accomplished at times with high calory or high carbohydrate diets. At other times it is better to let the patient eat large quantities of the foods he prefers and supplement his meals with small lunches in the morning, afternoon or before retiring. Meat is not contraindicated. In those with a large weight loss there is a secondary hypoproteinemia and meat is a necessity.

(c) Rest is obviously essential (see medical treatment). One qualification must be made. A patient kept at flat bed rest soon develops a profound weakness that makes him quite helpless during the reaction following an operation. His strength must be preserved by allowing him to be up and about several hours daily. No patient should be operated on immediately after complete bed rest.

The immediate preoperative orders are a full supper the night before the operation and, in addition, fruit juices or food at bedtime; Phenobarbital 0.1 Gm. and sodium bromide 1 Gm. (prescription 5) at 9 p. m.;

PRESCRIPTION 5.—Sodium Bromide Medication

R Sodium bromide	30.00 Gm.
Water	30.00 cc.
Syrup of glycyrrhiza	to make 120.00 cc.

Teaspoonful in milk after meals and at bedtime.

Compound Solution of Iodine 2 cc. in milk or grape juice in afternoon and forenoon; an enema in the morning; hypodermic injection of morphine sulfate 0.01 Gm. and atropine sulfate 0.5 mg. one-half hour before operation.

3. The choice of surgical procedure lies between a ligation of the superior thyroid vessels, subtotal removal of one lobe or a subtotal removal of both lobes and the isthmus. It is probable that a ligation does very little to the course of the disease and its indications are questionable. If, after from six to eight weeks of preparation the patient is still a poor risk, a subtotal removal of one lobe is advisable. The second lobe is best removed from four to eight weeks later, after improvement has occurred and before the fibrous adhesions have become too firm.

4. For postoperative care the patient needs fluids, food, rest and iodide. Water, orange juice, grape juice, lemonade or ginger ale is given by mouth soon after the operation. Some vomiting invariably occurs, but this need not stop the administration of fluids by mouth. A proctoclysis is to be continued off and on the first twenty-four hours to supplement the fluid intake. Physiologic solution of sodium chloride is preferable, since this replaces the chlorides lost in large quantities through sweat. If fluids are not retained either by mouth or by bowel, 5 per cent dextrose in physiologic solution of sodium chloride is given either by hypodermoclysis or by phleboclysis. Sodium iodide (1 Gm. or more) may be given in the proctoclysis or in the parenterally administered fluid. The second day, the iodide is continued by mouth. Morphine sulfate from 0.01 to 0.015 Gm. is administered frequently for either pain or restlessness. On succeeding days, pain and neuralgia can usually be controlled with acetylsalicylic acid (0.30 Gm. tablet repeated as frequently as required). The harassing cough responds best to codeine phosphate (prescription 6). A sitting posture is more comfortable on the first

PRESCRIPTION 6.—Codeine Phosphate Medication

℞ Codeine phosphate	0.50 Gm.
Water	2.00 cc.
Aromatic Syrup of Eriodictyon.....to make	60.00 cc.

Teaspoonful in a little water every hour for 3 doses, then as required (to check cough).

day. On the second day cramps and backache can be relieved somewhat by allowing the patient to lie in any comfortable position. On the third day he can be out of bed. The diet consists of anything that the patient will eat and it is increased as rapidly as he will tolerate it. A daily dressing even if not necessary, is comforting to the patient. Drains can be safely removed in forty-eight hours. The sutures in the skin should be removed in seventy-two hours unless one wishes to leave the patient as a permanent reminder of his operation a parallel series of stitch hole scars. Regardless of the technic used, in about a week serum collects under the scar, appearing first as a small fluctuating area in the scar, which later opens up leaving it permanently widened. This can be easily pierced with the point of the scissors, with avoidance at times of considerable disfigurement.

5. After the operation the immediate complications peculiar to thyroidectomy are (a) crisis, (b) hemorrhage, (c) obstructive dyspnea and (d) tetany.

(a) A crisis is a marked exaggeration of the usual postoperative reaction and its treatment is the same as the usual postoperative treatment; namely, fluids, dextrose, morphine and iodide. The fluid intake in a crisis should reach 5,000 cc. a day. The intravenous route is preferable but owing to the marked restlessness it may be impossible. Dextrose is given in as large amounts as can be utilized; that is, not beyond the appearance of glycosuria. Alcohol or other cool sponging and ice bags to the groin and the axilla will reduce the temperature. In auricular fibrillation strophanthin should be given intravenously, 0.25 mg. as the first dose. This may be repeated every eight hours for the first twenty-four hours, provided slowing of the pulse occurs within thirty minutes after each dose has been given.

(b) Bleeding may appear externally or may be hidden deep in the neck. The latter type is a frequent cause of obstructive dyspnea and is evidenced by a massive cylindric swelling of the entire neck. Opening

the wound, packing it or locating the bleeding point is the treatment demanded.

(c) Obstructive dyspnea is promptly recognized as a gradually increasing inspiratory stridor. The wound is examined for the swelling of a retained blood clot. If present, the wound is immediately opened. If not, the vocal cords are examined for a bilateral cord paralysis, unilateral cord paralysis plus edema, or edema alone. From the results one can decide on the necessity of a tracheotomy. In mild cases the administration of oxygen may carry the patient through until the edema subsides. As soon as any cyanosis appears, a tracheotomy should be done promptly; for these patients do not tolerate oxygen want for long.

(d) Tetany begins with numbness and tingling in the hands and feet, followed by stiffness of the muscles of the hand, then carpal and pedal spasm, occasionally laryngeal spasm, and finally convulsions. If, as soon as numbness and tingling appears, the patient is given 4 Gm. of calcium lactate every hour, the cramps will not set in. The dosage can be reduced to 4 Gm. three times a day the following days but must be continued for many months. Spontaneous improvement always occurs but a latent tetany exists which will require at least 1 Gm. of calcium lactate daily for an indefinite period. If cramps or convulsions are present, 10 cc. of 5 per cent calcium gluconate solution is given intravenously and repeated in fifteen minutes if necessary. The calcium lactate is then given by mouth. These measures will control nearly all attacks.

If not, parathyroid extract should be given (1 ampule every four hours) to tide the patient over the acute stage of hypocalcemia. Indefinite continuance of dosage of parathyroid extract is not indicated, as the system becomes immune to the drug.

B. Medical treatment: 1. Psychotherapy is of prime importance as emotion, especially suppressed emotion, is an important factor in the vicious circle prevailing in this disease. Emotion stirs the thyroid and the thyroid stirs the emotions. It is worry and anxiety, not work, that are harmful. Work that one dislikes, thwarted ambition, domestic infelicity and psychosexual maladjustment are potent factors. In all such cases one must either remove the patient from these untoward influences or make the patient tolerant to them, which can sometimes be done by the patient comprehending the fact that it is not the condition we live under but the revolt against it that is harmful. He must cultivate a peaceful poise.

2. Rest, both physical and mental, in degrees proportionate to the gravity of the case and in quality of a kind enjoyed by the patient, needs to be provided. Two weeks of absolute rest in bed is often a very good initial treatment.

3. Cold applications should be made locally. A flannel covered ice bag over the thyroid lessens pulsations and probably also the secretion of the thyroid. The ice bag over the precordium diminishes palpitation and slows the pulse in addition to the enforcing of rest.

4. Diet should be high in caloric value (from 5,000 to 6,000 calories) given in six meals a day. It should be high in carbohydrates, high in fat and relatively low in protein. Stimulants should be avoided.

5. To lessen the excitability, one may prescribe bromide (prescription 5) or its combination with phenobarbital (prescription 7) or, if these are insufficient, with the addition of codeine phosphate (prescription

6). Quinine hydrobromide (prescription 8) has been especially recommended as a sedative in exophthalmic goiter as well as because it lessens metabolic activity. The patient's relative immunity to cinchonism has been suggested as a diagnostic aid. It must be remembered that hyperthyroid patients are likely to be hypersensitive to nearly all other kinds of drugs. They are especially hypersensitive to epinephrine. In general, smaller than average doses of most drugs should be used initially.

6. Iodide certainly has a profound effect for good or ill. Small doses, such as five drops of the Syrup of Hydriodic Acid (prescription 3), may be tried, the effect being carefully watched and administration discontinued as soon as improvement seems to end. Larger quantities, e. g., prescription 1 in doses of 0.5 cc. in water three times a day, have greatly lessened the mortality of operation, if employed preoperatively and if the operation is undertaken at the moment of

PRESCRIPTION 7.—Sodium Bromide and Phenobarbital

Elixir of phenobarbital..... to make 120.00-cc.
Teaspoonful in milk after meals and two at bedtime.

optimal improvement. This amelioration is almost pathognomonic of the condition but, because of final aggravation that is to be expected, cannot be relied on for cure. There is no proof that iodide makes a case

PRESCRIPTION 8.—Quinine Hydrobromide

R Quinine hydrobromide 10.00 Gm.
Divide into 30 capsules.
Three capsules three times daily.

of true exophthalmic goiter worse, although the patient may, and usually does, grow worse in spite of prolonged iodide medication. If one wishes to use iodide as a curative drug, one should keep the patient under close observation. The moment improvement ceases, one should recommend an immediate thyroidectomy. Under this regimen little harm will ensue.

7. Gonadal substitution therapy may be worth trying in hyperthyroidism appearing at the menopause to bridge over the period of acute endocrine imbalance.

8. Symptomatic treatment should be given. The bowels should be kept open, preferably by Effervescent Sodium Phosphate, one or two teaspoonfuls in half a glass of water on arising. Deficiency of gastric hydrochloric acid may call for administration of the acid. Acidosis, a serious complication, occurring after operations, during infections and gastrointestinal upsets, should be treated by large quantities of water, dextrose and sodium bicarbonate. Heart failure due to auricular fibrillation is helped by digitalis (and rest in bed) and with smaller doses than are ordinarily required. Otherwise the tachycardia is not influenced by digitalis bodies. This is so definite as to be almost of diagnostic value.

C. For patients in whom the medical treatment is not sufficiently satisfactory and who refuse operation, roentgen irradiation offers some prospect of cure. As the skin of these patients is hypersensitive to the rays, a dose of 400 roentgens is given to the thyroid area by three ports (right, left and midportion) for three or more times at intervals of from three to six weeks. The results of each treatment should be checked by a basal metabolic test before the next one is given. As with surgical therapy, here too competent medical care before and afterward is a sine qua non to success. It may take six months before the full effect of the ray therapy can be estimated.

Special Article

VITAMIN A REQUIREMENTS AND PRACTICAL RECOMMENDATIONS FOR VITAMIN A INTAKE

LELA E. BOOHER, Ph.D.

WASHINGTON, D. C.

This article and others recently published or to be published comprise a new series on the present status of our knowledge of the vitamins. They have been prepared under the general auspices of the Council on Pharmacy and Chemistry and the Council on Foods. The opinions expressed are those of the authors and not necessarily the opinions of either council. Reprints are not available but the articles will be published later in book form.—Ed.

The estimation of vitamin A requirements necessitates the measurement of some physical or chemical criteria dependent on vitamin A intake. The known specific criteria which characterize a vitamin A deficiency in the animal organism have been summarized by Bessey and Wolbach.¹ Of the several recognized signs of vitamin A deficiency, it now appears that hemeralopia, or partial night blindness, is the earliest to appear. Fortunately it is a condition which lends itself readily to physical measurement. The amount of vitamin A that will just prevent hemeralopia probably represents something a little less than the minimum requirement. Certainly the vitamin A intake should not fall below the level that will be sufficient to prevent night blindness. A liberal margin of safety should be allowed for physiologic variations and for enabling the organism to lay by a store of this vitamin against such emergencies as illnesses attended with low or restricted intake of food. Still more liberal amounts should be provided for growing children, for persons recovering from wasting diseases and for pregnant and lactating women.

As a result of observations on the widespread and profound cytologic changes associated with vitamin A deficiency, Wolbach² has suggested that vitamin A is a structural material which may be solely concerned in maintaining an apparatus within cells and not in the chemical processes proper for which the apparatus is necessary. If such is the case, it would seem logical that vitamin A requirements should bear a definite relationship to the body weight rather than to energy metabolism, and in some of the data reviewed herein this deduction is strongly supported. A rough approximation of vitamin A requirements also would be obtained through a correlation of dietary surveys with the incidence of night blindness for large cross-sections of the population. Dietary surveys, resolved into terms of vitamin A intake, in conjunction with surveys of the incidence of night blindness made on the same group of persons, should furnish practical confirmation of the experimentally determined estimates of vitamin A requirements on relatively few rigidly controlled subjects.

A review of the work along these two lines of approach will reveal that only a feeble beginning has been made toward establishing a precise estimate of the

vitamin A requirements of human beings and of factors which affect these requirements. It is not to be implied that measurements of dark adaptation are all that is to be desired as evidence of adequacy or inadequacy of vitamin A intake; they probably represent the clearest evidence that exists for the present. Nor should it be assumed that the instruments and means available for such measurements are the last word in either simplicity or precision.

FACTORS AFFECTING VITAMIN A REQUIREMENTS

It is quite generally conceded that the most careful control of experimental laboratory animals has not been rewarded by uniformity of response to graded intakes of vitamin A. This being the case with so well standardized an animal as the rat has now come to be, one may logically expect even greater physiologic variation in the vitamin A requirements of human beings. The only practical solution to the problem is to allow a generous margin of safety over any estimate based on studies of human subjects necessarily limited in number. Experimentation on the human vitamin A requirements needs to be conducted over a considerable period of time in order to obtain a fair estimate for individual subjects.

Certain physiologic conditions have been reported³ to alter the utilization of vitamin A and its carotene precursors; for example: 1. Bile is essential for the utilization of carotene but apparently not for the utilization of vitamin A; also, if bile is shunted from the small intestine to the colon, the utilization of carotene is prevented. 2. Liquid petrolatum does not interfere markedly with absorption of vitamin A from the intestine but does inhibit the absorption of carotene. 3. The composition of the diet, other than its vitamin A content, has been reported to affect the absorption and utilization of both vitamin A and provitamin A.

Wilson, Das Gupta and Ahmad³ studied the influence of the fat content of the diet in relation to the absorption of the carotene of raw carrots or of cooked spinach in an adult human subject. They found that only about 50 per cent of the carotene was absorbed when the diet was devoid of fat, whereas from 80 to 90 per cent was absorbed when the diet contained moderate amounts of fat. Basu³ conducted similar but more extended experiments on the absorption of vitamin A and of carotene by white rats and concluded that different oils varied in their effect on absorption and utilization of vitamin A and of carotene according to the degree of unsaturation of the oil. Utilization was better with the more unsaturated oils. Basu also suggested that the essential unsaturated fatty acids may be linked with the utilization of the vitamin A activity of the food rather than that absence of the fatty acids in themselves represents a distinct dietary deficiency.

Friderichsen and Edmund⁴ have reported striking differences in the utilization of the vitamin A of fish liver oils and the carotene of carrots or spinach by young children under 2 years of age. The dried spinach induced discernible improvement in dark adaptation with about one tenth the dosage (in terms of interna-

tional units) required in the form of fish liver oils. The response with dried spinach was also greatly prolonged over that induced by fish liver oils. Relatively large quantities of carrot juice, mashed carrots or β -carotene often proved to be ineffective in restoring normal dark adaptation in young children who showed distinct evidence of subnormal dark adaptation.

It must be concluded that our knowledge of the factors which affect the utilization of the vitamin A activity of foods and of the physiologic conditions which may alter these is for the present very limited. Since it is customary to evaluate the vitamin A content of diets on the basis of biologic assay values as determined with laboratory animals (rats) and without regard to the particular vitamin A or carotene sources, the practical solution lies in providing for liberal amounts of vitamin A in the human diet.

VITAMIN A REQUIREMENTS FOR THE PREVENTION OF NIGHT BLINDNESS

The vitamin A units, as expressed throughout this article, refer to U. S. P. or international unit values in accordance with the requirements of the Council on Pharmacy and Chemistry⁵ for labeling vitamin A and vitamin D preparations.

Investigators have applied various means for the measurement of the rate of dark adaptation to the problem of estimating vitamin A requirements of human beings. These several methods, however, involve a principle which is common to all; namely, the measurement of the power of the eyes to adapt themselves to dim illumination. Some subjects are maximally adapted to the dark, and the light threshold measured immediately thereafter is taken as a criterion of dark adaptation; in other instances, the subjects are adapted to a moderately bright light (with or without preliminary dark adaptation) and measurements of light thresholds are made at intervals in darkness following this. Hecht⁶ has recently published a summary of the chemistry and kinetics of dark adaptation and has outlined the types of dark adaptation responses which follow adaptation to light of different intensities.

Friderichsen and Edmund⁴ made a study of 106 children under 2 years of age. The children were adapted to the dark for thirty minutes and then held at a distance of 10 cm. from a lamp, the apparent brightness of which could be varied by suitably graded filters for measurement of the light threshold. A child's positive response to light was indicated by certain characteristic reflex movements of the child's brow and eyelids. Although these workers developed a method which would seem highly promising if applied to the problem of the daily requirement of very young children for vitamin A, their work to date has been limited to a study of the utilization of carotene and vitamin A from different sources. Their observations have already been discussed.

Jeans and his co-workers⁷ have reported on the use of the Birch-Hirschfeld instrument, later displaced in their work by the "biophotometer," for the measurement of dark adaptation as a practical clinical method for detecting vitamin A deficiency. Although some criticism of the reliability and reproducibility of mea-

surements made with the biophotometer has been reported⁸ in a survey study of school children, other investigators⁹ have found the biophotometer and the Birch-Hirschfeld instruments satisfactory and useful for the purpose of detecting moderate degrees of night blindness. Feldman,¹⁰ Edmund¹¹ and Hecht⁶ describe the application of other means of measuring dark adaptation in which different sets of optical principles have been employed.

It would seem that the present difficulties surrounding any and all methods of measuring dark adaptation are at least as great as those involved in measuring basal metabolic rates. The method of Friderichsen and Edmund is limited to children so young that voluntary actions are not a complicating feature, but these authors mention that the tests are not easy to make but require great care, experience and knowledge of the reactions of small children. The methods adapted to older children and adults require the willing cooperation of the subject and an intelligence level corresponding to at least that of an average 6 year old child.

Observations by Jeans and his co-workers^{7c} on two 11 year old boys indicate that 3,000 units of vitamin A daily met their requirements as judged by the biophotometer test and standards which they consider normal responses. This level of vitamin A presumably is suggested not as the minimal level which would maintain normal dark adaptation but as an entirely adequate amount which might be considerably above the minimal requirement.

Jeghers,⁹ using the biophotometer test, has reported that the dark adaptation of a normal adult was not maintained at peak efficiency for more than about one week when the vitamin A intake was limited to 200 units a day, despite the fact that the subject had previously received massive daily doses of vitamin A for a period of three months. A normal adult (weighing 52 Kg.) subjected to a very similar dietary program and studied at the Bureau of Home Economics, U. S. Department of Agriculture,¹² but who had not taken vitamin A except for that available in an ordinary freely chosen diet, showed definitely impaired dark adaptation¹³ only after a period of approximately one month. After the impaired dark adaptation became apparent, it progressed with amazing rapidity until arrested by the administration of vitamin A. Whether this great difference in depletion of vitamin A reserves of the two subjects mentioned is indicative of the magnitude of the physiologic variations to be expected can only be left for further experimentation to determine. It might be of interest also to mention that the experimental subject studied at the Bureau of Home Economics showed no evidence of keratinization of the epithelium of the cornea at the time when dark adaptation was slowest but did show a marked constriction of the field of vision when tested¹⁴ by means of a

perimeter. A level of from 18 to 20 units of vitamin A (corresponding to about 6 micrograms of vitamin A) per kilogram of body weight resulted in very slow improvement in the dark adaptation of this subject, whereas from 30 to 35 units per kilogram of body weight soon restored and maintained maximum dark adaptation. This level would amount to approximately 2,100 to 2,450 units of vitamin A for an adult of 70 Kg.

Edmund and Clemmesen¹⁵ have recently reported a study of the vitamin A requirements of young adult men as carried out at the state prison in Nyborg (Denmark). Measurements of visual adaptation were made on twenty-eight young male prisoners in the summer and autumn of 1936, during which interval all the subjects received the fixed prison allotment of food. Following this the subjects were divided into two groups, one of which continued to consume this regular fare while the other group received in addition a half liter (about one pint) of whole fluid milk daily for a six month (autumn and winter) experimental period. The fourteen subjects receiving the fixed prison allowance, which contained an average of 1,225 units of vitamin A daily, showed seasonal oscillations in their powers of visual distinction (at different standard intensities of illumination) and occasional dysadaptation in some few cases. The subjects receiving the fixed prison allowance plus the milk supplement, the total food containing an average of 1,370 units of vitamin A daily, showed normal visual adaptation at all seasons. The vitamin A values assigned to the food items in the fixed prison allowance, being average values, do not disclose the natural seasonal variations in the vitamin A content of the food items. Actually the vitamin A intake of the control group would be a little more than 1,225 units during the summer months and a little less than 1,225 units during the winter months. It therefore required a year-round average of 1,370 units of vitamin A daily to provide an overall coverage for seasonal variations in the vitamin A values of the food in order to insure normal visual adaptations at all seasons. It was concluded, therefore, that about 1,400 units of vitamin A daily for an adult weighing from 68 to 69 Kg. would suffice for the support of normal visual adaptation.

According to Guilbert, Miller and Hughes,¹⁶ a level of vitamin A or carotene intake which is just sufficient to prevent gross signs of hemeralopia suffices also for excellent gains in weight and for maintenance of a thrifty physical appearance of animals for indefinite periods, although the storage of the vitamin in the body may be very meager indeed. These workers report that several species of animals (cattle, sheep and swine) differing widely in body weight showed almost identical requirements for vitamin A or carotene per kilogram of body weight for the prevention of hemeralopia. It was suggested that the minimal requirements of other vertebrate species, including the human being, might bear the same quantitative relationship to body weight. A daily intake of approximately 40 to 50 units¹⁷ in the form of carotene ("25 to 30 micrograms of carotene") or about 20 to 30 units¹⁷ of vitamin A ("6 to 8 micrograms of vitamin A") per kilogram of body

17. The U. S. P. or international units have been calculated by the author from the data as given by the investigators, 0.6 microgram of carotene and 0.3 microgram of vitamin A being considered equivalent to one U. S. P. or international unit. The quotations give the quantities in the terms used by the investigators.

weight was found to be sufficient for the prevention of night blindness in these three species of animals. If the same requirement per kilogram of body weight holds for the human species, a man weighing 70 Kg. would require daily about 1,400 to 2,000 units of vitamin A or, roughly, double this number of units in the form of carotene as a "physiologic minimum."

Experimentation with animals has shown¹⁶ quite conclusively that liberal allowances of vitamin A over and above the daily requirement which will support normal dark adaptation, an average growth rate and an outward thrifty physical condition are essential for maintaining bodily reserves of vitamin A and for the successful bearing and rearing of young. Experiments with animals have shown¹⁸ that a liberal intake of vitamin A is also conducive to longevity and to prolonging the prime of life.

On the basis of the limited number of quantitative studies on record, it would appear that the vitamin A requirements for the prevention of partial night blindness in adults was of the order of from 25 to 30 units per kilogram of body weight daily, or a total of approximately 1,400 to 2,000 units daily for an adult weighing 70 Kg. It would also seem that the daily intake of vitamin A per kilogram of body weight of adults required for the prevention of night blindness might be very nearly a constant for vertebrate species of animals generally. However, further quantitative studies on the vitamin A requirements of children are necessary in order that children's requirements may be interpreted in relation to adult requirement. Many more studies will also be needed before the magnitude of physiologic variation in vitamin A requirement can be estimated.

ANALYSIS OF DIETARY SURVEYS IN TERMS
OF VITAMIN A INTAKE

Dietary surveys resolved into terms of the essential food constituents, when compared with dietary requirements for the same food essentials, furnish a general index of the probable nutritive status of different population groups. In addition, these surveys point the way to specific means for dietary improvements.

The practical problem of food selection is influenced by several factors operating simultaneously and including family income or, more precisely, the amount of money spent for food, degree of urbanization, individual preference and application of available knowledge of foods and nutrition. In general, the classification of dietaries according to the amount of money spent for food per adult capita shows a distinct gradation in the qualities of the diets. Within any one of these classes further differences are observed according to the degrees of urbanization. With specific reference to vitamin A, it is quite obvious that foods rich in vitamin A are not the least expensive of the ordinary food items. The families living in cities or on farms in each region tend to be provided with more liberal allowances of vitamin A than families living in villages. The most probable explanation of this is that the city dwellers have access to good markets; the farm families can provide themselves with milk, butter and eggs as well as garden produce from their own farms, while the village folk, generally, share less of either of these advantages.

The average adult vitamin A intake daily was computed from a dietary survey made during the year 1935-1936 in different regions of the United States. At present data for the average vitamin A values of the

common foods determined directly in terms of U. S. P. or international units are insufficient for the purpose of evaluating the total vitamin A value of ordinary mixed diets. The vitamin A values of most of the common food items are, however, available in terms of Sherman units of vitamin A. Information furnished by several laboratories of recognized standing and having extended experience with the U. S. P. method of vitamin A assay indicate, from the growth rates of vitamin A assay rats which were fed the standard U. S. P. reference cod liver oil, that the value in Sherman units divided by a factor of from 1.5 to 2 is approximately equivalent to the value in U. S. P. or international units.¹⁹ The data for the dietary survey reported in the accompanying table were originally computed in terms of Sherman units of vitamin A. For purposes of correlation with the rest of the observations reported here these values

have been divided by 2 as probably representing a fair approximation in terms of U. S. P. or international units of vitamin A.

The data in this table show quite strikingly how the average vitamin A intake varies with the amount of money available for food and for any one "food-spending group" with the degree of urbanization. A careful examination of the specific food items actually consumed by these different population groups also showed the need for popular education on the subject of foods

19. Dr. E. M. Neison, Food and Drug Administration, U. S. D. A., states in a personal communication: "When U. S. P. units of vitamins A and D based on international units for these vitamins came into use it seemed desirable to acquaint investigators in this country with the approximate relative values of international units and units which had previously been used in this country. On the basis of data obtained in assay of the U. S. P. reference cod liver oil against the international standard for vitamin A, it was possible to make an estimation of these relative values. The U. S. P. Vitamin Advisory Board issued a statement in which it was stated that 1 U. S. P. X Sherman or American Drug Manufacturers' Association vitamin A unit was approximately equivalent to 1.4 international or U. S. P. X (Revised 1934) vitamin A units. It was stated: 'These conversion factors should not be considered as having any official recognition.' Since that time it has become apparent that the conversion factor proposed at that time was inaccurate. Most of the assays that have come to my attention since that time show that 1 international unit of vitamin A will promote a growth rate in excess of 3 Gm. per week during the assay period in the U. S. P. method, indicating that a given product would contain fewer international than Sherman units. Since manufacturers of pharmaceutical preparations changed their assay procedure so as to determine vitamin A potency directly in terms of U. S. P. X (Revised 1934), or international, units this inaccuracy has been of no particular moment in the labeling of such products, and for this reason the U. S. Pharmacopoeia had not concerned itself further with conversion factors of different vitamin A units."

18. Batchelder, Esther L.: Nutritional Significance of Vitamin A Throughout the Life Cycle, *Am. J. Physiol.* 109: 430-435 (Sept.) 1934.

and nutrition. While some families had too little money to buy a fully adequate food supply regardless of how carefully they might select it, still a large proportion now existing on poor diets would be able to obtain a fully adequate diet if they had applied the present knowledge of nutrition to the problem of the best selection of food.

It is apparent that many members of families in the lower income groups probably are on the borderline of a recognizable vitamin A deficiency. Because each of these group averages embraces rather wide individual variations in vitamin A intake, it is to be expected that a fair proportion of persons in the lowest income groups actually receive less than the "physiologic minimum" requirement of vitamin A. This deduction is amply borne out by other surveys on the incidence of partial night blindness.

Jeans and Zentmire^{7b} tested 404 country and village school children of Iowa from 6 to 15 years of age and found latent night blindness in 26 per cent of the country children and in 53 per cent of the village children. The highest incidence of night blindness was found in families of the lowest income classes.

Maitra and Harris⁹ found definitely subnormal dark adaptation among elementary school children (from 8 to 14 years of age) in London and Cambridge to the extent of about 30 per cent of the 193 children examined. These investigators also found a tendency toward higher incidence of hemeralopia among the younger children of the group.

The vitamin A reserves of new-born infants have been reported²⁰ to be very low, the livers of infants being found to contain only about 14 to 17 units of vitamin A per gram in contrast to an average of 220 units of vitamin A per gram reported²¹ for the livers of healthy adults. The vitamin A reserves of a well fed infant rise very rapidly during the first few months of life. The premature and artificially fed infant needs special attention with regard to the vitamin A supply of the food.

A very high incidence of "dysadaptation" has been found among pregnant women. Edmund and Clemmesen²² report that 50 per cent of the pregnant women admitted to a Copenhagen municipal hospital showed signs of subnormal visual adaptation.

PRACTICAL RECOMMENDATIONS FOR VITAMIN A INTAKE FOR PERSONS OF DIFFERENT AGES

The physiologic minimum requirement of vitamin A for a man weighing 70 Kg. would appear to be on the order of from 1,400 to 2,000 units of vitamin A daily. Provision for a supply of vitamin A which furnishes barely enough to prevent measurable signs of deficiency is of course unsound and in serious opposition to the best interests of the health and welfare of subjects at any age. A 50 per cent margin of safety, providing 3,000 units of vitamin A daily for an adult weighing 70 Kg., would seem to be none too liberal in view of the facts that there may be considerable physiologic variation in the requirement for vitamin A, that at least a moderate storage probably is highly desirable and that there is some question about the relative utilization of the carotene sources of this vitamin.

The Technical Commission for the Study of Nutrition of the Health Organisation of the League of

Nations recommends²³ an allowance of from 2,000 to 4,000 units daily for an adult as fully adequate on the basis of an intake of 500 cc. of whole fluid milk, one egg, 25 Gm. of butter and a medium serving of a green, leafy vegetable daily. This recommendation of from 2,000 to 4,000 units of vitamin A was suggested in view of the range of from 1,400 to 3,000 units suggested by different investigators as a minimum requirement, the latter range being partly or mainly accounted for, it was supposed, by differences in the vitamin A content assigned to common foods by various workers.

The diets of infants and young children usually contain more milk than the diets of adults, and their diets are frequently supplemented with some kind of fish liver oil, so that in comparison with well nourished adults the well fed infant probably receives a considerably larger amount of vitamin A per kilogram of body weight. Any extra needs associated with rapid rates of growth would thus be taken care of as well as reasonable provision for building up a bodily reserve of vitamin A. It would seem important in the case of both premature infants and artificially fed infants to pay even more particular attention to the inclusion of liberal amounts of the so-called protective foods in order to permit them to build satisfactory bodily reserves of vitamin A and to supply adequate amounts of minerals and other vitamins as well.

The Technical Commission of the Health Committee of the League of Nations has recommended²⁴ that all children between the ages of 2 and 14 years be provided with about 1 quart of milk daily, in addition to an egg, servings of green, leafy vegetables and butter suited to the size of the child, and 3 Gm. of cod liver oil daily as the main sources of protective foods rich in vitamin A. These recommendations probably would provide for at least 6,000 to 8,000 units of vitamin A daily for growing children. For a more specific account of these recommendations the reader is referred to the publication cited.

A very effective means of dealing with the problem of supplying an adequate vitamin A intake for children of school age would be to serve carefully planned school lunches which would furnish liberal amounts of the so-called protective foods. Rose and her co-workers²⁵ and Hann and Stiebeling²⁶ have shown in very practical terms how school lunches may be planned to furnish more than 50 per cent of the probable vitamin A requirements of children of nursery and elementary school ages and to improve the diets of the children in other ways at one and the same time.

The Technical Commission of the Health Committee of the League of Nations recommends²⁴ a daily intake of at least 5,000 U. S. P. or international units of vitamin A for the pregnant and nursing woman. In terms of food items this may be translated as 1 quart of fresh, whole milk, one egg, 1 ounce of cheese, an average serving of a green, leafy vegetable and 1 teaspoonful of cod liver oil daily.

SUMMARY

The daily requirement for vitamin A just sufficient for the prevention of night blindness in a normal adult would appear to be on the order of from 20 to 30

U. S. P. units of this vitamin per kilogram of body weight, or a total of about 1,400 to 2,000 units daily for an adult weighing 70 Kg.

Allowing for a fair margin of safety and for the maintenance of a moderate storage of vitamin A in the body, a total of around 3,000 units of vitamin A daily is suggested for the normal adult. In view of other qualities of nutritional excellence provided by milk, butter, eggs and green leafy vegetables, these food items should be used in quantities which will provide a large proportion of this vitamin A allowance.

Provision of around 6,000 to 8,000 units of vitamin A daily for the growing child would presumably be adequate to take care of any extra needs associated with growth and development and to provide for a moderate bodily storage of vitamin A. A small supplement of some fish liver oil in addition to liberal quantities of whole milk, butter, eggs and green leafy vegetables is recommended for children in view of the excellence of these food items in vitamin A and other nutritive essentials important for the growing child. Particular attention should be paid to supplying the infant and even more especially the premature or artificially fed infant with liberal quantities of vitamin A, since infants are born with very meager stores of vitamin A in their livers.

The recommended allowance of vitamin A for pregnant and nursing women has been set at around 5,000 units or more daily, with a further suggestion that this allowance be supplied mainly by liberal amounts of milk, butter, cheese, eggs, green leafy vegetables and some small addition of fish liver oil.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT.

H. A. CARTER, Secretary.

SPERTI SUN LAMP NOT ACCEPTABLE

Manufacturer: Science Laboratories, Inc., 424 East Fourth Street, Cincinnati.

It is one of the functions of the Council on Physical Therapy to report from time to time on newly marketed devices recommended for use in physical therapy, particularly those which have elicited a number of inquiries from the public. The new Sperti Sun Lamp has been considered, after being purchased on the open market. This Sperti Sun Lamp (table model), Type SL 110, is entirely different in construction from the device reported on in *THE JOURNAL*, May 15, 1937, page 1713.

Tests were made on the erythematogenic effects and radiation characteristics of the lamp by a reliable investigator. The Sperti Sun Lamp is designed to operate on from 105 to 125 volts alternating current, 60 cycles, and, according to the manufacturer, it uses about 150 watts of electricity. The heart of the sunlamp is the burner, which consists of a thin-walled cylindric glass tube, about 2 cm. in diameter and about 13 cm. long, that contains mercury vapor. The length of the mercury arc between the electrodes is about 8 cm. The burner is mounted in a chromium-plated cylindric reflector, on a flexible standard that permits projection of the rays in various directions. The massive base contains a reactance which forms part of the operating equipment of the burner.

SPECTRAL AND TOTAL ULTRAVIOLET RADIATION MEASUREMENTS

The lamp was operated on 110 volts, alternating current 60 cycles, under which conditions the power used, as measured with a watt meter, was 85 watts. Under these conditions the ultraviolet spectral intensities at 3,663 angstroms and shorter

wavelengths were found to be closely the same as that of a Uviarc "hot" quartz mercury arc lamp. Evidently the thin-walled glass burner transmits ultraviolet radiation quite freely to wavelengths shorter than 2,537 angstroms. The manufacturer states that this sunlamp generates ultraviolet out to this wavelength, and in four places in his booklet of "Operating Instructions and General Information About the Sperti Sun Lamp" warns the user of this lamp, "You must wear goggles."

The total intensity of the ultraviolet including 3,132 angstroms and shorter wavelengths was 32.1 microwatts per square centimeter at 24 inches (61 cm.) from the front edge of the burner. Of this amount 31.7 per cent, or about 10.5 microwatts per square centimeter, is of wavelengths shorter than about 2,900 angstroms and 31.2 per cent is in the emission line at 2,537 angstroms.

In view of the fact that in sunlight there is no ultraviolet of wavelengths shorter than about 2,900 angstroms, it is evident that the ultraviolet emission of the Sperti "mercurlite" lamp is not representative of a Sun Lamp and, hence, is not acceptable for home use without the supervision of a physician.

ERYTHEMA TESTS

Erythematogenic tests also indicate the close agreement in spectral emission between the Sperti lamp and the hot quartz mercury arc. The erythematogenic effect on the untanned inner forearm was determined at a distance of 24 inches (61 cm.) from the front edge of the burner. The exposures ranged from fifteen to forty-five minutes, in five minute increments. At the end of four hours all exposures were quite red, characteristic of the erythema produced by the emission of short wavelength radiation, at 2,537 angstroms. The following day the erythema caused by the fifteen and twenty minute exposures had disappeared. The exposure for a minimum perceptible erythema was estimated to be between twenty-five and thirty minutes; the latter value was the calculated time of exposure. In terms of the hot quartz mercury arc lamp of the same intensity, the exposure would be twenty-seven minutes for a threshold erythema.

At a distance of 1 foot the time of exposure would be about one-fourth the value, or between six and seven minutes. The time of exposure recommended by the manufacturer is five minutes, at a distance of 1 foot.

In order that a lamp of this type may be representative of a "Sun Lamp" acceptable to the Council, it should be covered with a window of Corex D glass, 2 mm. in thickness, which is opaque to radiation of wavelengths shorter than 2,800 angstroms.

Tested with a Corex D window, and exposure at 1 foot, the Sperti Lamp produced a minimum perceptible erythema in about thirty minutes, which is not too prolonged for a home-model lamp.

Two pieces of advertising matter were examined by the referee. The first, "Operating Instructions," is on the whole acceptable, provided the lamp is sold only to physicians. However, if the pamphlet is to be distributed with the lamp when sold for home treatments, many of the claims will have to be altered to conform with radiation characteristics when Corex D glass is added. It is also noted that "sunlight starvation" is mentioned as a common cause for colds and other diseases. Critical evidence has not been presented to support these statements.

In the other pamphlet, "Here's a Genuine Mercury-Arc Sun Lamp," there are several objectionable features. The name is misleading, since the lamp as it stands is not a "Sun Lamp" but a "Therapeutic Lamp." Claims are made here that ultraviolet will build up the reserve physical energy and aid in the prevention of colds and common diseases, as well as promote a clear complexion.

In view of the foregoing report, the Council on Physical Therapy voted not to include the Sperti Sun Lamp, Type SL 110, in its list of accepted devices because (1) the ultraviolet radiation emitted does not conform with the requirements adopted by the Council for sun lamps, and (2) the advertising matter contains misleading or unwarranted claims.

TRAUMA AND APPENDICITIS

Probably because trauma, next to cold, is associated in the minds of people with almost every disease, the first impulse of the surgeon is to reject the possibility as a cause of appendicitis. Deaver said that he had never seen a genuine case of traumatic appendicitis. John B. Murphy, however, as early as 1892 urged that trauma could be an exciting factor in appendicitis, and Howard Kelly claimed that traumatic appendicitis is more frequent than is commonly believed. He collected records of fifty cases, and Osler in his "Practice of Medicine" stated that "trauma plays a very definite role, and in a number of cases the symptoms have followed very closely a fall or a blow."

Three distinct opinions prevail. One categorically denies the existence of acute traumatic appendicitis and regards the occasional association of trauma with an attack of appendicitis as a coincidence. Another accepts the possibility of causal relationship but limits the role of injury to that of an activating factor bringing about an exacerbation in a previously diseased organ, denying at the same time that trauma per se is capable of originating an acute attack in a previously healthy appendix. Finally, there is the belief that traumatic appendicitis is a definite clinical entity. The latter opinion is gaining a wider recognition both by the medical experts and by the courts, which in recent decisions have recognized traumatic appendicitis as a compensable cause under the laws governing industrial compensation.

The exact mechanism of traumatic appendicitis has not been definitely elucidated. The trauma may be direct, such as a blow to the abdomen, a kick or a fall on the abdomen, or the pinioning of the abdomen against a fixed object. Indirect forces of violence are prolonged muscular strain or untoward or unusual sudden muscular action. Direct traumatization of the appendix or of its mesentery has been demonstrated in a few cases in which an immediate operation was performed. This, however, in view of its rarity, is in all probability not a true *modus operandi* in the majority of the cases. One cannot therefore accept

the postulate of Sprengel or of Fowler¹ that in order to prove a case of traumatic appendicitis one must be able to demonstrate at operation true traumatic lesions of the appendix, such as contusion, hematoma, laceration or rupture, and the presence of free blood in the peritoneal cavity. Ludington² clearly points out that even were such traumatic lesions present the advancing inflammation would soon mask them to the degree that they could not be recognizable at the time of operation and that the pathologic alterations present would therefore not differ from other cases of acute appendicitis.

A far more plausible theory, and one in harmony with our concept of the pathogenesis of acute appendicitis, is that of overdilatation of the organ by the influx of cecal contents as the result of trauma. Radiologists know that cecal contents may be forced into the appendix with the aid of moderate pressure. Fürbringer and von Hansemann³ were able to express the contents of a full cecum into the appendix by light manual pressure over the cecum, by light manual pressure over the ascending colon and by the introduction of air into the rectum. A blow on the abdomen or a muscular strain which increases the intracecal pressure could therefore force cecal contents into the appendix. The future course of events would depend on the condition of the organ. A normal appendix with a free lumen would empty itself of the material forced into it and would probably escape damage. In the presence, however, of chronic pathologic conditions, such as compressing or angulating adhesions, scars, fibrosis of its walls and particularly in the presence of coproliths, there exist, as Ludington pointed out, conditions favorable to the development of acute appendicitis; namely, a lumen obstructed by a coprolith, fecal stasis, defective drainage of the distal segment and an increase in the virulence of the contained organisms. Fecaliths are frequently found in the appendix in cases of traumatic appendicitis. They were present in thirty of Kelly's fifty cases; according to Brünig they were present in 65 per cent of the traumatic cases as contrasted with 35 per cent in the nontraumatic cases. They were found either in the lumen or in the free peritoneal cavity in each of the four cases reported by Bissell.⁴ Bissell believes that "the trauma caused the concretion to impinge tightly in the lumen of the appendix resulting in an obstruction in that organ, with hemorrhagic infarction, necrosis and perforation on the antimesenteric border."

The pertinent question is not whether trauma can originate an initial attack of appendicitis or whether its effect is that of lighting up dormant pathologic conditions. It is, rather, whether or not trauma can precipitate a clinical attack of acute appendicitis. The

consensus is not only that it can but that the resulting attack is likely to be one of a grave, destructive type, with a clear clinical picture. Usually, after a blow on the abdomen, a kick, a fall, or a sudden muscular strain, severe sharp abdominal pain occurs, followed by vomiting. The initial pain and vomiting are characteristic and are presumably due to intraperitoneal shock. Then, in most cases, as pointed out by Behan,⁵ both symptoms cease and return later, as the result of progression of inflammatory changes within the abdomen. Rarely is there any evidence of bruising of the abdominal wall. There may be muscle rigidity and well localized tenderness over the right lower quadrant. Such a clinical picture should suggest the possibility of acute appendicitis. Procrastination is serious because of the severe destructive lesions characteristic of this entity.

IMMUNOLOGIC FACTORS IN WHOOPING COUGH

The processes of infection and recovery in whooping cough have long been puzzling. Several years ago Mishulow, Mowry and Scott¹ and later Toomey and McClelland² demonstrated that the causative organism, *Haemophilus pertussis*, produces a soluble toxic substance. On the basis of an extensive study,³ Toomey of Western Reserve University in 1936 proposed the theory^{3a} that bacteria of the virulent or "phase I" type initiate the disease in human beings and release a toxin to which the patient becomes sensitized. This sensitization was assumed to coincide with the occurrence of the characteristic lymphocytosis. "Phase I" bacilli, on injection into guinea pigs, were found more virulent than organisms recovered later in the disease;^{3c} they produced agglutinins in the blood serum of rabbits in high titers.^{3e} Yet, at the time the virulent organisms may be obtained most easily from patients, the latter suffer only from coryza. As the whoop starts and the patient becomes clinically worse, virulent organisms are found less easily, though the characteristic mucoid material which causes the whoop may be recovered in large amounts.

Toomey^{3d} acclimated *Haemophilus pertussis* to various mediums and rendered the organisms avirulent;

he was thus able for the first time to produce in vitro the tenacious mucoid material characteristic of the clinical disease. Virulent ("phase I") organisms failed to produce this mucoid substance under any condition.^{3e} These facts led the Cleveland investigator to suggest that infection and immunity in whooping cough are characterized by a dual mechanism: 1. At the beginning of the disease the patient becomes sensitized to the virulent "phase I" organisms and their soluble antigen; this is followed by gradual desensitization. 2. By the onset of the whooping stage the causative bacilli have become avirulent but at the same time produce a mucoid by-product, to which the patient must develop immunity.

Sensitization actually occurs in pertussis, as shown by the fact that antisera produced in animals by injecting virulent organisms not only do not ameliorate the clinical disease but actually aggravate it. Such sera also fail to protect infected animals.³ⁱ On intradermal injection of mixtures of antiserum and suspensions of *H. pertussis* or a culture filtrate of these organisms, the local reaction is enhanced rather than diminished. Toomey has found further that patients with whooping cough show a gradual increase in local reaction to culture filtrates of *H. pertussis*.^{3b} Thompson⁴ has recently reported that cutaneous reactions to *H. pertussis* endotoxin become definitely positive about the tenth day of the disease and subsequently increase, ultimately regressing; he has suggested that this material may be useful as a cutaneous test.

Using an ingenious technic, Galavan and Goodpasture⁵ at Vanderbilt University have reproduced in the pulmonary tissues of chick embryos lesions identical with those occurring in the human being. In addition to providing further substantial proof that *H. pertussis* is the actual cause of the disease, these investigators have found evidence, in agreement with Toomey's theory, that "the injurious effect is the result of some toxic product of the growing bacillus acting locally." More recently Sprunt, Martin and McDearman⁶ of Duke University have reported the production of lymphocytosis and interstitial pneumonia in monkeys and rabbits by intratracheal injection of *H. pertussis*. The course of the disease in these animals was found to accord with Toomey's hypothesis, with which the Duke investigators are in essential agreement.

After devising a method of obtaining in vitro the mucoid material produced by the whooping cough bacillus, Toomey investigated the possibility of hastening the development of immunity and thus recovery in patients by injecting solutions of this substance.^{3h} In a number of cases rapid amelioration of the distressing symptoms occurred. As Toomey points out,

however, definite conclusions as to the efficacy of this therapy cannot be drawn until many hundreds of cases have been treated.

These investigations of Toomey and others have now elucidated many of the perplexing clinical manifestations of whooping cough and promise to provide more effective prevention, diagnosis and treatment of this disease.

ALCOHOLIC PARALYSIS OF LOCAL IMMUNITY

Experimental pathologists are agreed that infected animals die sooner as a result of alcoholic intoxication than nonintoxicated controls. The manner in which alcoholic intoxication lowers resistance, however, has not been determined. Kenneth L. Pickrell¹ of Johns Hopkins University passively immunized a relatively large group of rabbits to pneumococci of type I and then injected each animal intracutaneously with 0.1 cc. of an eight hour pneumococcus culture. An equal number of nonimmune rabbits were used as controls.

Half of the animals of each immune and nonimmune series were intoxicated with ethyl alcohol and maintained in a stuporous condition throughout the experiment. In both intoxicated and nonintoxicated nonimmune rabbits positive blood cultures were obtained within five hours, and death occurred within eighteen hours. The nonintoxicated immune rabbits did not show a positive blood culture and all survived the infection. The intoxicated immune rabbits, however, acquired septicemia as promptly as the nonimmune controls, death taking place within twenty-four hours. Alcoholic intoxication apparently rendered these immune animals wholly nonresistant to endermic infection with pneumococci.

The presumptive mechanism of alcoholic deimmunization was deduced from a microscopic study of the lesion in and around the site of injection. In nonintoxicated animals an edematous, hyperemic and purpuric lesion occurred, particularly obvious in the nonimmune group. Microscopic examination revealed a dense leukocytic infiltrate. In the nonintoxicated immune group bacteria could not be demonstrated microscopically after the ninth hour in these leukocyte-infiltrated tissues. In the intoxicated rabbits, gross lesions did not develop in or around the site of the injection and there was practically no leukocytic infiltration, but bacteria were present in swarms in the tissues of both the passively immunized and non-immunized animals. Experiments in which the bacteria were introduced into the lungs by way of the trachea gave results quite like those of the intracutaneous experiments.

The effect of alcoholic intoxication on the activity of leukocytes was investigated in twenty-four animals. In this experiment 5 cc. of aleuronat suspension was injected into the pleural cavity. Eighteen hours later,

half of the aleuronat-injected rabbits were intoxicated. After two hours of intoxication, type II pneumococci were injected into the pleural cavity. Smears of the pleural exudate made forty-five minutes later showed abundant phagocytosis in both the intoxicated and the nonintoxicated groups. No differences in phagocytic index were noted. Differential counts in warm stage preparations showed no differences in the percentage of motile and nonmotile leukocytes in the blood streams of intoxicated and nonintoxicated rabbits. The loss of pneumococcus resistance, therefore, is presumably not due to an alcoholic injury of the leukocytes but to a local inflammatory paralysis of central or peripheral origin.

In a parallel study of the effects of ether anesthesia, the Johns Hopkins investigators showed that there was a similar local inflammatory paralysis with loss of pneumococcus resistance as a result of prolonged ether anesthesia.

Current Comment

HUMAN REQUIREMENT FOR VITAMIN C

As the result of the isolation in pure form and chemical identification of several of the vitamins, it has been possible to begin evaluation of the role of each of these substances in health and disease. Moreover, more precise knowledge of the chemical behavior of these dietary essentials has permitted the development of chemical methods for detection and quantitative measurement, methods which are invaluable substitutes for the more laborious biologic assays. It then becomes possible to apply these methods to normal and pathologic conditions and to establish definitely the relative importance of each vitamin as well as the normal requirements. Determinations of the vitamin C requirement of human beings have indicated that the necessary daily dose, for a normal adult of 70 Kg., is as high as 60 mg.¹ This quantity, corresponding to the cevitamic acid content of about 4 ounces of lemon juice, is probably excessive, judged both by the value of 20-30 mg. obtained by Göthlin² through the use of the capillary resistance test and by the recent report of Schultzer.³ The latter investigator determined the urinary excretion of cevitamic acid in a patient with scurvy of moderate severity. It was first established that the determination of the saturation point, that is, the amount of constant vitamin C ingestion which is required to produce a fairly constant excretion of this vitamin, is an incorrect approach to the problem of the minimum daily requirement, since the total quantity of cevitamic acid necessary to reach saturation may vary with the size of the daily dose. Whereas patients with scurvy studied in earlier investigations took from 7 to 14 Gm. of vitamin C over three to five weeks (several hundred milligrams daily) before they were saturated, the present report deals with a patient who received only 40 mg. a day, intravenously for twenty-three days,

1. Van Eekelen, Marie: *Biochem. J.* **30**: 2291 (Dec.) 1936.
2. Göthlin, G. F., *Skandinav. Arch. f. Physiol.* **61**: 225 (May) 1931.
3. Schultzer, Paul: *Biochem. J.* **21**: 1934 (Nov.) 1937.

1. Pickrell, K. L.: *Proc. Soc. Exper. Biol. & Med.* **28**: 265 (March) 1933.

becoming saturated after receiving a total quantity of vitamin C calculated at less than 1 Gm. From the fact that no difference was found in the time required for vitamin saturation, whether the dose of the vitamin was large or small, it is concluded that saturation tests of this kind do not offer means of estimating the reserve stores of vitamin C in the organism or of estimating the daily requirement for this vitamin. However, as 40 mg. of vitamin C injected intravenously proved to be a curative dose for a patient with moderate scurvy, it is suggested that the daily human requirement can be placed at this level or possibly less. The intravenous pathway of administration serves to eliminate complicating gastro-intestinal factors and aids in establishing more accurately the exact minimum daily human requirement, as has also been emphasized by Wright, Lilienfeld and MacLenathen.⁴ It may well be that the varying results of the different laboratories may be brought into harmony if distinction is made between actual requirement and indispensable minimum, the latter being the amount that is sufficient to prevent scurvy and the former also including that quantity of vitamin C necessary for normal functioning of all body processes which may require, or be influenced by, vitamin C. Certainly a moderately accurate statement of the exact human requirement for vitamin C can now be made when the results of all investigators are considered.

GOVERNMENT ACTIVITY AGAINST POISONOUS CONTAMINANTS

Recently the Food and Drug Administration has been issuing monthly news releases concerning its actions. Under the subheading "Other Food Seizures" (March 22) reference is made to "54 gallons and 310 small bottles of flavors and solvents containing poisonous glycols; and 515 bushels of apples carrying excessive spray residue." Similar seizures are reported also for April. Certain glycol-containing solvents for flavors (other than glycerin) have been widely used. Fortunately, the amounts ingested were small. The recent Elixir of Sulfanilamide-Massengill incident focused attention on diethylene glycol. Toxic glycols have been used in the food and drug industry, such as "Carbitol," which is the mono-ethyl ether of diethylene glycol; this apparently is more acutely toxic than diethylene glycol. The dosages containing "Carbitol" were so small that deaths apparently occurred rarely if at all. One pharmaceutical concern did market three or four preparations for therapeutic use containing carbitol; as soon as articles concerning diethylene glycol appeared in THE JOURNAL the firm promptly ceased manufacturing the drug products. The Food and Drug Administration began to trace a large number to see that they had been removed from the market. From time to time THE JOURNAL has warned against the potential harm of sprays for fruits containing lead or arsenic. The government deserves considerable encouragement in having reduced this hazard by requiring careful removal of spray residue from fruits sold in interstate commerce. The work of the Department of

Agriculture in the study of lead hazards has been hampered by the fact that the last Congress failed to provide for the adequate continuance of the work in the department. The hazard of lead cannot be attributed to any one industry or source; the possibility of lead intake should be eliminated from every source if possible. Whether the source of lead is contamination of drinking water, the increasing amount of lead of exhausts from automobiles, fruit sprays from lead solder or other sources, it is a hazard. The plan of attack should be to lessen the total intake by eliminating as far as possible the presence of lead compounds from every conceivable source.

Association News

THE SAN FRANCISCO SESSION

Special Radio Programs

Radio programs, in addition to the regular weekly broadcast *Your Health*, have been arranged in connection with the annual session of the American Medical Association in San Francisco.

Dr. J. H. J. Upham, President of the Association, will broadcast over the Red network of the National Broadcasting Company Monday, June 13, from 3:30 to 3:45 p. m., Pacific standard time. Dr. Irvin Abell, President-Elect, will broadcast over the Columbia Broadcasting System Thursday, June 16, from 5:15 to 5:30 p. m., eastern daylight saving time.

Dr. W. W. Bauer will broadcast over the Red network of the National Broadcasting Company June 16 from 12 midnight to 12:15 a. m. eastern standard time (eastern daylight saving time is four hours later than Pacific standard time; eastern standard or central daylight saving time is three hours later than Pacific standard time; central standard time is two hours later than Pacific standard time; mountain standard time is one hour later than Pacific standard time).

RADIO BROADCASTS

The American Medical Association and the National Broadcasting Company present the fifth series of network health programs, beginning Oct. 13, 1937, and running weekly through June 15, 1938. The programs are presented over the Red network each Wednesday at 12:30 p. m. eastern standard time; central standard time is one hour earlier, mountain standard time two hours earlier and Pacific time three hours earlier than eastern standard time.

In localities where daylight saving is in effect, the schedule remains the same but this brings the program one hour earlier to adjacent areas on standard time.

The dates and topics of the broadcasts for the next three "Your Health" programs are as follows:

Using Health Knowledge

- June 8—Graduation and Then What: a new phase of life begins at commencement, and health contributes to success.
- June 15—What Medicine Offers for Health: flashes from the American Medical Association meeting at San Francisco, giving highlights of medical progress.

The June 15 program closes this series of dramatizations. A new series will begin early in October.

The stations on the Red network are privileged to broadcast the program, but since it is a noncommercial program they are not obliged to do so. Interest on the part of medical societies, woman's auxiliaries and others may have weight with program directors of local stations. A personal visit to the program director might be advisable if the program is not being taken by a local station. This is an opportunity for the appropriate committees of county medical societies to indicate their interest in having this program broadcast in their community and to enlist the interest of other groups.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

New Health District.—The East Alabama Health District, including the counties of Bullock, Chambers, Lee, Macon, Randolph, Russell and Tallapoosa, has recently been organized with headquarters at Opelika. The new unit is the outgrowth of a field training base at Opelika, which has been conducted by the state department of health. In connection with the unit the Rockefeller Foundation has for several years sponsored a clinical research study in tuberculosis, placing particular emphasis on the incidence of this disease in a typical rural southern county and on practical methods of dealing with the problem in the absence of adequate hospital facilities. The new health district aims to serve as a practical teaching center and a demonstration area for specialistic health services. Of the population of approximately 212,000 in the area, about 100,000 persons are white and 112,000 are Negroes. The Rockefeller Foundation and the Commonwealth Fund are providing financial support for the district, the former by developing a program for the control of tuberculosis and the latter by strengthening and expanding certain other consultant and specialized services. Dr. Arthur H. Graham, formerly in charge of the Rockefeller Foundation's tuberculosis study project in Lee County, has been named medical director of the new health district. Dr. Paul W. Austin, formerly associated with Dr. Graham, will serve as tuberculosis expert. Sidney H. Morrow, D.D.S., Birmingham, is in charge of the mouth hygiene program and Dr. Harry L. Mueller, Detroit, is the pediatrician. Mr. G. S. Christopher, formerly a member of the bureau of sanitation, state department of health, will direct the sanitation program, and Miss Velma M. Owen, formerly county nurse in Walker, Limestone and Calhoun counties, will be in charge of nursing activities. Other personnel will be added later, according to the state medical journal.

ARKANSAS

State Medical Election.—Dr. Albert S. Buchanan, Prescott, was named president-elect of the Arkansas State Medical Society at its annual meeting in Texarkana April 20 and Dr. Sidney J. Wolfermann, Fort Smith, was installed as president. Other officers are Drs. Robert R. Kirkpatrick, Texarkana; Charles G. Hinkle, Batesville, and Smith W. Douglas, Eudora, vice presidents; Royal J. Calcote, Little Rock, treasurer, and William R. Brooksher, Fort Smith, secretary. The next annual session will be held at Hot Springs National Park.

Society News.—The Ouachita County Medical Society was addressed at Camden recently by Drs. James T. Robison on "Value of X-Ray in Obstetrics"; Robert R. Kirkpatrick, "Earache," and Harry E. Murry, "Hemorrhaging Ulcers of the Stomach and Duodenum." All are of Texarkana.—At a meeting of the Miller County Medical Society recently Drs. Francis Walter Carruthers and Merlin J. Kilbury, both of Little Rock, spoke on "Circulatory Diseases of the Extremities" and "Physiologic and Pathologic Sections of the Cervix and Uterus."—Dr. Maurice W. Chastain addressed the Benton County Medical Society at Bentonville, March 10, on "Diseases of the Coronary Arteries," and Emmett A. Pickens, "Diagnosis and Treatment of Coronary Thrombosis."—At a meeting of the Lawrence County Medical Society in Imboden March 8 the speakers included Dr. Wright W. Hatcher, Imboden, on undulant fever.—The Sebastian County Medical Society was addressed March 8 by Drs. Ira B. Oldham Jr. on "Traumatic Surgery of the Extremities"; Finis W. Ewing, "The Mafe Climacteric," and Edwin H. Coachman, "Diphtheria Carriers"; all are of Muskogee, Okla.

CALIFORNIA

A Harvey Evening.—The Hollywood Academy of Medicine and the Library Associates cooperated May 19 in holding a Harvey evening at the Hollywood Roosevelt Hotel. Dr. Charles N. B. Camac discussed "Social and Scientific Environment in Which Harvey Worked" and the Harvey film, illustrating his experiments, was shown.

Society News.—The Kern County Medical Society was addressed in Bakersfield May 4 by Dr. Udo J. Wile, Ann Arbor, on "Treatment of Congenital and Prenatal Syphilis."

—At a meeting of the Monterey County Medical Society in Salinas April 6 Dr. Howard E. Clark, Monterey, spoke on common diseases of the eye.—The speakers before the San Joaquin County Medical Society, Stockton, April 7, included Dr. Ernest C. Dickson, San Francisco, on coccidiosis.—At a meeting of the Alameda County Medical Association in Oakland May 16 the following spoke: Drs. Leonard Wood, on "Surgical Aspects of Ruptured Ovarian Cysts"; Harry J. Templeton, "Present Campaign Against Syphilis," and Charles A. Dukes, "Can We Improve Our Treatment of Cancer?"

COLORADO

Personal.—Dr. Charles A. Davlin, Alamosa, has been elected president of the state board of health, succeeding Dr. Paul J. Connor, Denver, who resigned from the board. Dr. Robert W. Dickson, Denver, was recently appointed a member of the board to succeed Dr. Connor.

Society News.—The historical section presented a special program before the Medical Society of the City and County of Denver May 3; the speakers were Dr. Josiah N. Hall on "Early Day Indian Troubles as I View Them" and Mr. F. H. Douglas, curator of Indian art, Denver Art Museum, "Medicine, Surgery and Obstetrics as Practiced Among the Indians." The medical society was addressed April 5 by Drs. George B. Kent and Kenneth C. Sawyer on "Treatment of Cancer of Colon and Rectum."—The Colorado Hospital Association held its semiannual meeting at the Beth-El Hospital, Colorado Springs, May 25.—The Pueblo County Medical Society was addressed in Pueblo April 5 by Drs. J. Sims Norman and Dwight B. Shaw on "Recent Developments in the Treatment of Fractures of the Extremities." The society was addressed April 19 by Dr. Casper F. Hegner, Denver, on chest surgery.—A recent meeting of the Fremont County Medical Society was addressed in Florence by Drs. Laurence E. Berg and Raynor E. Holmes Jr., Canon City, on duodenal ulcer.—Dr. Aeneas P. Cash discussed intravenous anesthesia before the Otero County Medical Society, La Junta, recently.—At a meeting of the Washington-Yuma Counties Medical Society recently Dr. William T. H. Baker, Pueblo, among others, spoke on diseases of the breast.

CONNECTICUT

Dr. Alling Retires.—Dr. Arthur N. Alling, since 1902 clinical professor of ophthalmology, Yale University School of Medicine, has retired. He has been connected with the medical school since 1893 and will now be a consultant on the staff of the New Haven Hospital after having served as an attending surgeon and ophthalmologist-in-chief since 1914. Dr. Alling graduated in medicine at Columbia University College of Physicians and Surgeons in 1891. He is the author of "Diseases of the Eye" and "Ocular Therapeutics."

GEORGIA

State Medical Election.—Dr. William H. Myers, Savannah, was chosen president-elect of the Medical Association of Georgia at its annual meeting April 29 and Dr. Grady N. Coker, Canton, was inducted into the presidency. Vice presidents are Drs. Peter B. Wright, Augusta, and William B. Schaefer, Toccoa. Dr. Edgar D. Shanks, Atlanta, was reelected secretary-treasurer. The next annual session will be held in Atlanta, May 9-12, 1939.

ILLINOIS

New Full Time Health Districts.—The state department of health announces that the following physicians have been placed in charge of the recently established full time health districts:

Dr. James A. Poling, Freeport, District 4, comprising Lee and Ogle counties.
Dr. Carl A. Peterson, Moline, district 5a, Henry and Mercer counties.
Dr. Sander Horwitz, Peoria, district 6, Marshall, Peoria and Putnam counties.
Dr. John P. Walsh, Greenview, district 11, Case, Logan and Macon counties.
Dr. Robert H. Bell, Carlinville, district 12, Calhoun, Greene, Jersey, Macoupin, Morgan, Scott and (emergency) Bond, Madison and Montgomery counties.
Dr. Nettie A. M. Dorris, Paris, district 13, Champaign, Coles, Douglas, Edgar, Vermilion counties.
Dr. Joseph L. Bryan, Xenia, district 14, Clay, Clinton, Effingham, Jasper, Marion and (emergency) Fayette.
Dr. Roy W. Harrell, P. O. Box 161, Carbondale, district 15a, Jackson, Monroe, Perry, Randolph, Washington, and (emergency) St. Clair.
Dr. Roland R. Cross, Dahlgren, district 18, Franklin, Hamilton, Jefferson, Wayne and White.
Dr. Lewis S. Barger, Golconda, district 29, Gallatin, Hardin, Johnson, Massac, Saline, Pope and Williamson counties.
It is planned to have twenty health districts in the state on a full time basis.

Chicago

Alumni Dinner.—The annual alumni-faculty banquet of the University of Illinois College of Medicine will be held at the Medinah Club June 9 at 6:30 p. m. A special feature will be the opening of the cornerstone "box" of the old college building. According to the announcement, no one living at present knows the contents. Reservations should be made with Dr. Michael H. Streicher, 1853 West Polk Street.

Experimental Center on Visual Education.—A conference on visual education and the adult May 13-14 marked the establishment of an experimental center for the development of this field at Northwestern University. Topics discussed included visual aids in industry, in community programs and in college classes, while special features included exhibits of audiovisual equipment and films publicizing the work of schools and other community projects.

Ricketts Prize Awarded to Anatomist.—Dr. John Marshall Weir Jr., formerly assistant professor of anatomy, University of Mississippi Medical School, has been awarded the Howard Taylor Ricketts Prize of the University of Chicago for his researches on the Schwartzman reaction in the lung. The prize was established in 1913 to honor Dr. Ricketts. Dr. Weir received his bachelor of science degree from the University of Chicago in 1933; he received both his degrees of medicine and of philosophy in 1937.

Chicago Tumor Institute Receives Ten Grams of Radium.—Ten grams of radium have arrived in Chicago for the Chicago Tumor Institute. The entire amount will be used in the form of a radium pack. The apparatus which has been specially designed for maximum flexibility and protection includes a system of remote electrical control as an added safeguard for the patient and personnel. The entire unit is housed in a specially constructed lead and concrete chamber. The radium was obtained from the Union Minière du Haut Katanga, Brussels. The ten gram pack which permits treatment at distances not practical with smaller quantities will be used for treatment and research with special emphasis on comparative studies between radium pack therapy and supervoltage x-ray therapy.

INDIANA

Society News.—Dr. Maurice R. Lohman, Fort Wayne, was elected president of the Indiana Tuberculosis Association at its annual meeting, succeeding Dr. Charles J. McIntyre, Indianapolis. —Russell W. Bunting, D.D.S., dean, University of Michigan School of Dentistry, Ann Arbor, discussed "The Control of Dental Caries" at a joint meeting of the Indianapolis medical and dental societies April 19. —Dr. Leslie L. Vescen, Chicago, discussed "Value of X-Ray in Urologic Diagnosis" before the Northeastern Indiana Academy of Medicine, April 28, in Kendallville. —Dr. Norman F. Miller, Ann Arbor, addressed the Fort Wayne Medical Society March 15 on "The Quality of Obstetrical Care." —Dr. Wayne R. Glock discussed hip fractures before the Academy of Medicine and Surgery in Fort Wayne recently.

Changes in the Faculty at Indiana.—The state medical journal reports, among others, the following changes in the faculty at the University of Indiana School of Medicine, Indianapolis:

- Dr. Frank F. Hutchins, professor emeritus of mental and nervous diseases.
- Dr. Max A. Bahr, professor and chairman of the department of mental and nervous diseases.
- Dr. Edgar F. Kiser, clinical professor of cardiovascular renal diseases.
- Dr. Robert M. Moore, clinical professor of cardiovascular renal diseases.
- Dr. Cyrus J. Clark, associate professor of cardiovascular renal diseases.
- Dr. Robert L. Glass, assistant professor of surgery and Huesmann fellow in neurologic surgery.
- Dr. Frederic W. Taylor, assistant professor of pathology and assistant in plastic surgery.
- Dr. Amos C. Michael, assistant professor of general pathology.
- Dr. Ko Kuei Chen, professor of pharmacology.
- Harold R. Hulpieu, Ph.D., associate professor of pharmacology and biochemistry.

The name of the department of rhinology, otology and laryngology was changed to the department of otolaryngology.

IOWA

Pediatric Meeting.—The first annual meeting of the Iowa Pediatric Club was held at the Hotel Fort Des Moines, Des Moines, April 8. The guest speaker was Dr. Julius H. Hess, Chicago, on "Chicago's Program for the Care of Premature Babies." Other speakers included Drs. Walter L. Biering, Des Moines, state health commissioner, on "The National Program on Maternal and Child Health"; Julian D. Boyd, Iowa City, "Behavior Disorders in Childhood," and Fred Moore,

Des Moines, "Nephrosis: Complicated by Pleural Effusion, Ascites, Cellulitis, Strangulated Omental Hernia and Peritonitis. Treatment: Acacia Transfusion. Recovery." A symposium on epidemic sore throat and scarlet fever was presented by Drs. Fred Sternagel, West Des Moines, Thomas E. Eyres and Harry E. Ransom, Des Moines.

Dr. Jepson Honored.—Dr. William Jepson, Sioux City, has been appointed professor emeritus of surgery at the State University of Iowa College of Medicine, Iowa City, it is reported. Dr. Jepson taught surgery at the school from 1902 to 1913. He also served as professor of surgery at Sioux City College of Medicine from 1891 to 1901. Dr. Jepson graduated at the State University of Iowa College of Medicine in 1886 and the University of Pennsylvania School of Medicine, Philadelphia, and Jefferson Medical College in 1891; he became a licentiate of the Royal College of Physicians of Edinburgh and Royal College of Surgeons of Edinburgh and Royal College of Physicians and Surgeons, all in 1897. He has been president of the state board of medical examiners, Tri-State Medical Society, Iowa State Medical Society and the Sioux Valley Medical Society.

LOUISIANA

State Medical Election.—Dr. Clarence A. Lorio, Baton Rouge, was chosen president-elect of the Louisiana State Medical Society at its annual meeting in New Orleans May 4 and Dr. Joseph A. O'Hara, New Orleans, was installed as president. New vice presidents include Drs. Cassius L. Peacock, New Orleans; Jerome E. Landry, New Orleans, and Paul D. Abramson, Shreveport; Dr. Paul T. Talbot, New Orleans, was reelected secretary. The next annual session will be in Alexandria.

Society News.—The Orleans Parish Medical Society was addressed April 25 by Drs. Erwin Wexberg on "Present State of Insulin and Metrazol Treatments of Schizophrenia"; Sydney Jacobs, "Chronicity of Tuberculosis" and Edward P. A. Ficklen, "Amebic Abscess of the Liver." The society was addressed April 11 by Drs. Clyde Brooks on "Deuteroproteose and Specified Serum in the Treatment of Pneumonias"; Manuel Gardberg, "Protamine Insulin in the Treatment of Diabetes Mellitus," and Henry Theodore Simon, "Some Fractures of the Upper Extremity."

MASSACHUSETTS

Society News.—The annual meeting of the Trudeau Society was addressed in Waltham May 17, among others, by Mr. Manfred Bowditch on "The State's Experience with Silicosis," and Dr. Francis P. Dawson Jr., "Spontaneous Pneumothorax: A Suggestion for the Treatment of Acute Symptoms." —At a meeting of the Boston Society of Psychiatry and Neurology, May 19, the speakers included Drs. Roland S. Schwab on "A Method of Measuring Consciousness in Petit-Mal Epilepsy" and Dr. Tsung-hwa Suh, "The Vascular System of the Human Spinal Cord." —Dr. Robert A. Moore, New York, discussed "Benign Enlargement of the Prostate" before the New England Pathological Society in Boston, May 19. —Dr. Frederick T. Lord, Boston, was elected president of the Massachusetts Tuberculosis League at its recent annual meeting. —Dr. Cecil K. Drinker, Boston, addressed the Massachusetts Public Health Association at its meeting April 27, among others, on "The Spread of Infections in the Respiratory Tract." —Dr. Abraham Colmes read a paper before the South End Medical Club, Boston, May 17, entitled "Simplifying the Approach to Clinical Allergy." —The William Harvey Society, Boston, was addressed May 13 by Dr. Frank H. Lahey, Boston, on "Thyroid Surgery and Thyroid Disease and Some of Its Newer Developments." Dr. John R. Fraser, Montreal, discussed obstetrics and gynecology before the society April 23.

MICHIGAN

Library Named in Honor of the Late Dr. Manwaring.—The library of Hurley Hospital, Flint, was dedicated to the memory of the late Dr. Joshua G. R. Manwaring, Flint, in a ceremony April 13. When the personal collection of Dr. Manwaring, constituting more than 1,000 volumes, was recently donated to the hospital by Mrs. Manwaring, it was decided to name the library in his honor. The unveiling of a plaque was a feature of the ceremony. Dr. Manwaring died April 17, 1934. He was a member of the House of Delegates of the American Medical Association in 1930 and at one time served as president of the Genesee County Medical Society. He was a founder of the American College of Surgeons and served on the staff of Hurley Hospital.

MONTANA

Personal.—Dr. Julio R. Soltero, Lewistown, has been reappointed health officer for Fergus County.

State Medical Election.—Dr. Harold W. Gregg, Butte, was named president-elect of the Medical Association of Montana at the meeting of the house of delegates April 26. Dr. James C. MacGregor, Great Falls, was installed as president and Dr. Thomas L. Hawkins, Helena, was reelected secretary. The next meeting will be at Butte.

NEBRASKA

District Meetings.—A meeting of the Ninth Councilor District was held in Grand Island March 31 with the following speakers: Drs. Abram E. Bennett, Omaha, on "Treatment of Syphilis"; William J. Arrasmith, Grand Island, "Surgical Jaundice," and A. F. Donaghue, Sioux City, Iowa, "Backache." Following a banquet Dr. Charles W. M. Poynter, Omaha, made an address on "The Doctor in Literature." Dr. Homer Davis, Genoa, president of the Nebraska State Medical Association, was a guest and Dr. Eugene C. Foote, Hastings, showed motion pictures of a trip to Alaska.—The Tenth Councilor District Society met at the Hastings State Hospital April 7. Papers were presented by Drs. Frederick W. Niehaus, Omaha, on "Coronary Heart Disease"; Albert H. Fechner, and Louis R. Nash, Ingleside, "Shock Treatment by Insulin and Metrazol."

NEW JERSEY

County Tuberculosis Hospital Opened.—The Hudson County Tuberculosis Hospital, Jersey City, a \$3,000,000 building with a capacity of 510 beds, was recently opened for patients. The building was begun in 1934 and completed in 1936, but installation of equipment was only recently completed. A federal PWA loan and grant amounting to \$2,996,000 financed the construction and an appropriation by the county was used for furnishings. Built on the side of a hill, the hospital is twenty-five stories high on the taller side. It is of setback construction from the seventh to the fourteenth floor, the section in which patients' rooms are located, so that each floor has a sun deck. Most of the rooms are for one or two patients and none have more than four beds. The sixteenth floor is devoted to open pavilions for air baths and to sun lamp rooms. Dr. Berthold S. Pollak is medical director of the hospital, which is part of the Jersey City Medical Center. The center now includes also a general hospital, a maternity hospital, a psychiatric hospital, a hospital for infectious diseases and a clinic building. The old hospital will be used for convalescent patients and as a preventorium for tuberculous children. Mayor Frank Hague of Jersey City laid the cornerstone of the tuberculosis hospital at a ceremony Nov. 4, 1937.

NEW YORK

Conferences on Syphilis.—The state department of health and the council committee on medical education of the Medical Society of the State of New York conducted a series of conferences on syphilis for practicing physicians. The schedule was as follows: Buffalo April 26-27, Syracuse May 18-19, Watertown May 20, Jamestown May 23, New York May 23-24, Binghamton May 24-25 and Albany May 26-27.

Society News.—Dr. Anthony C. Cipollaro, New York, addressed the Sullivan County Medical Society, Liberty, May 4 on "Diagnosis and Treatment of Tuberculosis and Allied Conditions."—Dr. Clayton W. Greene, Buffalo, addressed the Genesee County Medical Society, Batavia, April 1 on diagnosis and treatment of common heart diseases.—Drs. Edward C. Reifstein and Arthur B. Raffi, Syracuse, addressed the Madison County Medical Society, Oneida, April 14 on "The Present Status of Sulfanilamide," and "Diseases of the Thyroid Gland" respectively.

New York City

Human Death from Rabies.—A youth 17 years of age died from rabies in the Willard Parker Hospital May 18, according to the *New York Times*. This is the first death to have occurred in New York from rabies since July 1930, it was stated. The boy had been bitten on the little finger of each hand by a dog April 18.

Society News.—Dr. William H. Meyer addressed the New York Roentgen Society April 18 on "A Qualitative-Quantitative Concept of Radiation Therapy."—At a meeting of the New York Pathological Society April 28 the speakers were Drs. Andrew A. Marchetti on "Certain Types of Benign Tumors

of the Placenta"; Robert J. Parsons and Philip D. McMaster, "The Passage of Substances Through Tissues and the Formation of Lymph."—Speakers before a joint meeting of the New York Neurological Society with the section of neurology and psychiatry of the New York Academy of Medicine May 10 were Drs. Joseph H. Globus on "The Topography of a Probable Sleep-Regulating Center"; Walter O. Klingman, "Treatment of Neurogenic Megacolon by Selective Drugs," and Philip R. Lehrman, "Psychopathological Aspects of Emotional Divorce."—Dr. Simon R. Blatteis, Brooklyn, presented "An Epidemiological and Clinical Analysis of Brill's Disease" before the Medical Society of the County of Queens May 6.

Dr. Cole Receives Kober Medal.—Dr. Rufus Cole, director of the Hospital of the Rockefeller Institute since 1909, received the George M. Kober Medal for distinguished service to medicine from the Association of American Physicians at its annual meeting in Atlantic City May 4. The presentation was made by Dr. Frederick F. Russell, Boston, who commented in particular on Dr. Cole's work on pneumonia and the pneumococcus. A native of Rowsburg, Ohio, and 66 years of age, Dr. Cole graduated in medicine at Johns Hopkins University, Baltimore, in 1899. He served as assistant instructor and associate in medicine and at his alma mater from 1901 to 1909, when he became director of the Hospital of the Rockefeller Institute. He is a member of the Board of Scientific Directors of the International Health Division of the Rockefeller Foundation and in 1931 was president of the Association of American Physicians.

NORTH CAROLINA

State Medical Election.—Dr. William Allan, Charlotte, was chosen president-elect of the Medical Society of the State of North Carolina at its annual meeting in Pinchurst May 4 and Dr. James Buren Sidbury, Wilmington, was installed as president. Vice presidents are Drs. Claude B. Williams, Elizabeth City, and Millard D. Hill, Raleigh. Dr. Thomas W. M. Long, Roanoke Rapids, was reelected secretary.

Public Health Election.—Dr. Joseph A. Morris, Oxford, health officer of Granville County, was chosen president of the North Carolina Public Health Association at its twenty-eighth annual meeting in Pinchurst May 2. Dr. Avon H. Elliott, Wilmington, health officer of New Hanover County, was named vice president, and Dr. John William Roy Norton, Raleigh, assistant director of the division of preventive medicine, state board of health, secretary-treasurer.

OHIO

State Medical Election.—Dr. Parke G. Smith, Cincinnati, was chosen president-elect of the Ohio State Medical Association at its annual meeting in Columbus May 11-12, and Dr. Barney J. Hein, Toledo, was installed as president. Other officers include Dr. James A. Beer, Columbus, treasurer, and Mr. Charles S. Nelson, Columbus, executive secretary. The next annual session will be in Toledo, the date to be determined in July.

OKLAHOMA

Changes in Faculty.—At a meeting of the board of regents of the University of Oklahoma, Oklahoma City, April 4, the following promotions were approved, among others:

Dr. James Patton McGee, assistant professor of ophthalmology to associate professor of ophthalmology.

Dr. Joseph C. MacDonald, assistant professor of otorhinolaryngology to associate professor of otorhinolaryngology.

Dr. Joseph W. Kelso, assistant professor of gynecology to associate professor of gynecology.

Society News.—The Southeastern Oklahoma Medical Association held an all day session at Durant April 26; the speakers included Drs. Allen R. Russell, McAlester, on acute conditions of the abdomen as seen by the general practitioner; Elbert H. Shuller, McAlester, arthritis, and Neil D. Bue, Marlin, Texas, state and national medical legislation.—At a meeting of the Carter County Medical Society in Ardmore, April 25, the speakers were Drs. Robert C. Sullivan, Ardmore, on peptic ulcer; Fred T. Perry, Healdton, sulfanilamide; William K. Ishmael, Oklahoma City, "Physical Therapy Correlated with Medical Treatment of Arthritis," and Howard B. Shorbe, Oklahoma City, "Orthopedic Correction of the Deformed Joints in Arthritis."—Dr. Wendell M. Long, Okemah April 18 on "Practical Aids in Pelvic Examination" and Basil A. Hayes, "Changes in the Upper Urinary Tract Due to Pelvic Pathology." Both speakers are from Oklahoma City.

PENNSYLVANIA

New State Sanatoriums.—Ground was broken May 2 for the new Western Pennsylvania State Tuberculosis Sanatorium at Butler for which the state has allotted \$2,645,000. The institution will include a main hospital building, children's wing, nurses' home, employees' dormitories, medical director's residence and auxiliary buildings, and will accommodate 500 adult and fifty child patients. Recently the rebuilding of the state tuberculosis sanatorium at Mont Alto was undertaken. New buildings to replace old frame structures will include an infirmary, a children's hospital, nurses' home, dining hall and kitchen, employees' dormitory and some auxiliary buildings. There will be accommodations for 400 beds for children and 500 for adult patients. The state has appropriated \$4,765,000 for the project.

Philadelphia

University News.—The University of Pennsylvania and Swarthmore College, Swarthmore, will eventually receive the bulk of the \$200,000 estate of the late Dr. Edward Martin, Media, Pa. Relatives are to receive the income from the estate after several gifts are deducted, and after the last survivor has died three fifths of the principal goes to Swarthmore for support of the Edward Martin Biological Laboratory, given to the college by a friend of Dr. Martin. The remaining two fifths will go to the University of Pennsylvania for scholarships and fellowships in the school of medicine.

Fund to Study Arthritis.—The Bryn Mawr Fund for Investigation of Chronic Arthritis has recently been established with an anonymous gift of \$30,000. It will be used at the Bryn Mawr Hospital and the University of Pennsylvania School of Medicine and must be spent within the next three years at the rate of \$10,000 a year. According to the newspapers, the donor has indicated that if worthwhile results have been obtained at the end of the specified period he would finance a continuation of the work. The fund will be administered by a committee consisting of Dr. George D. Wagoner, Haverford, director, laboratory of research orthopedics, in the medical school; Dr. Thomas Klein of the Bryn Mawr Hospital staff and professor of clinical medicine, Temple University School of Medicine; Dr. MacKinnon Ellis of the hospital staff; Dr. Max M. Strumia, pathologist at the hospital, and Dr. George Wilson. As the first step in the application of the gift, the hospital opened a clinic on arthritis May 10 to continue every Tuesday.

TENNESSEE

Society News.—Dr. Philip C. Schreier addressed the Memphis and Shelby County Medical Society March 15 on "Functional Disorders of Menstruation" and Dr. Nicholas Gotten and Cleveland S. Simkins, Ph.D., "Spinal Cord Abscess."—Dr. James L. L. Bibb, Chattanooga, addressed the Coffee County Medical Society, Manchester, March 2 on coronary thrombosis.—Dr. Martin A. Blanton, Mosheim, addressed the Greene County Medical Society, Greeneville, March 1 on "Acute Respiratory Diseases."

Tumor Clinic at Meharry.—Dr. Heddy S. Shoulders, professor of roentgenology at Meharry Medical College, Nashville, has been appointed director of a tumor clinic to be established at the school, and Dr. John H. Hale associate director. A committee of the faculty which will be responsible for working out methods and policies includes in addition Drs. John J. Mullooney, president of the college, Edward L. Turner, William S. Quinland, Garland N. Adamson, Robert J. Warner and E. B. Cole, D.D.S. The clinic was made possible by the gift of \$20,000 from Mr. Edward S. Harkness, New York, and a fund of \$10,000 raised by the college.

TEXAS

Syphilis Among Maids.—The Dallas Syphilis Clinic under the auspices of the city health department at the Parkland Hospital recently reported that 51,000 treatments were given during 1937. A city ordinance requiring domestic servants to have routine Wassermann tests went into effect January 3. Of about 5,000 maids examined, 32 per cent were found to be infected and most of them were sent to the clinic for treatment.

Personal.—Dr. Holman Taylor, secretary, Texas State Medical Association, was the guest of honor at a testimonial banquet in Fort Worth April 8. The occasion marked his retirement as brigadier general commanding the sixty-first field artillery of the National Guard. Dr. Taylor is a member of the recently appointed Committee on Supply of Medical Service of the American Medical Association.—Dr. William N.

Powell has been elected chairman of the city health commission of Temple, succeeding Dr. Arthur C. Scott Jr., who resigned to become a director of the Brazos River Conservation and Reclamation District.

WISCONSIN

Society News.—Drs. Lindon Seed and Tell Nelson, Chicago, addressed the Brown-Kewaunee-Door Counties Medical Society, Green Bay, March 15, on "Infections of the Neck" and "Allergy in General Practice" respectively.—Speakers before the Eau Claire-Dunn-Pepin Counties Medical Society March 28 were Drs. James S. McCartney and William T. Peyton, Minneapolis, on "Postoperative Pulmonary Embolism" and "Cavernous Hemangioma and Its Treatment" respectively.—Drs. Robert L. Wilder and Oswald S. Wyatt, Minneapolis, addressed the La Crosse County Medical Society, La Crosse, March 8, on "Cryptorchidism" and "Acute Appendicitis in Children" respectively.—Dr. Frederick B. Moorehead, Chicago, addressed the Outagamie County Medical Society, Appleton, March 24, on "The Use of Elastic Traction in the Treatment of Jaw Fractures and in Plastic Surgery."

GENERAL

Two Periodicals Merge.—Announcement is made of the incorporation of the *Review of Tumor Therapy* and *Southern Surgeon*. Financial difficulties were responsible for the change, it was stated.

Meeting of Dermatologists.—The American Dermatological Association will hold its sixty-first annual meeting at the Hotel Del Monte, Del Monte, Calif., June 9-11, under the presidency of Dr. James H. Mitchell, Chicago. Among the speakers will be:

- Dr. Thomas W. Murrell, Richmond, Va., The Positive Wassermann in Spirochetal Infections Other Than Syphilis—Report of a Case.
- Dr. Hammett A. Dixon, Toronto, Ont., Melanotic Sarcoma with Extreme Melanosis.
- Dr. Clarence Guy Lane, Boston, Jaundice Occurring During the Treatment of Syphilis.
- Dr. John G. Downing, Boston, Skin Diseases of Industrial Workers: A Review of Two Thousand Claims for Compensation.
- Dr. Hiram E. Miller, San Francisco, The Chronic Granulomas in Industrial Dermatology.
- Dr. Harold N. Cole and James R. Driver, Cleveland, Manufacture of War Gases and Their Relation to Industrial Medicine.

American Radium Society.—The twenty-third annual meeting of the American Radium Society will be held at the Clift Hotel, San Francisco, June 13-14, under the presidency of Dr. Edward H. Skinner. The speakers will include:

- Dr. Leland R. Cowan, Salt Lake City, Low Voltage Lightly Filtered X-Radiation versus Radium and High Voltage in the Treatment of Superficial Cancer.
- Dr. Grant H. Beckstrand, Long Beach, Calif., Treatment of Breast Cancer and Calculations of Dosages Delivered by Radiation Therapy.
- Dr. Daniel G. Morton, San Francisco, Adenocarcinoma of the Uterine Fundus.
- Drs. William P. Healy and Robert L. Brown, New York, Experience with Radiation Therapy Alone in Carcinoma of the Corpus Uteri.

The annual dinner will be held Monday evening. Dr. Henry Schmitz, Chicago, will deliver the Janeway Lecture on "Historical Retrospect of the Treatment of Carcinoma of the Uterus" and the Janeway Medal will be presented.

Study of Internal Secretions.—The twenty-second annual scientific session of the Association for the Study of Internal Secretions will be held at the St. Francis Hotel, San Francisco, June 13-14. The following will speak, among others:

- Drs. Clarence J. Kurth and Daniel V. Conwell, Halstead, Kan., Insulin Therapy in Mental Diseases.
- Dr. Henry H. Turner, Oklahoma City, Infantilism with Congenital Webbed Neck and Cubitus Valgus.
- Warren O. Nelson, Ph.D., Detroit, The Relation of the Anterior Pituitary to the Development of the Thyroid Glands.
- Dr. Edwin C. Thompson, Chicago, The Therapeutic Use of the Sex Steroids.
- Drs. Willard C. Thompson, Fred B. Thompson, Samuel G. Taylor III and William S. Hoffman, Chicago, The Treatment of Addison's Disease with Adrenal Cortex Extract.

Fred C. Koch, Ph.D., Chicago, will deliver his presidential address at the annual dinner Monday evening on "The Control of the Gonads Over the Pituitary." Edward C. Kendall, Sc.D., Rochester, Minn., will also address this meeting on "The Role of Biochemistry in Endocrinology."

Alumni Meetings.—The alumni of Jefferson Medical College will hold a smoker at the Union League Club, 555 Post Street, San Francisco, Wednesday evening, June 15 at 9 o'clock.—A banquet and dance for members of the Phi Delta Epsilon Fraternity will be held Wednesday evening June 15 at the Concordia Club, Van Ness and Post streets, San Francisco. Reservations may be made at the registration booth of the fraternity at registration headquarters.—The alumni of Harvard University Medical School will hold a dinner at the

Palace Hotel, San Francisco, June 15; reservations should be made with Dr. William J. Kerr, University of California Hospital, San Francisco.—The Phi Beta Pi Medical Fraternity will hold a banquet in San Francisco June 15. All members of the fraternity are asked to register at the Phi Beta Pi booth at the same time they register for the convention.—Alumni of Washington University School of Medicine, St. Louis, will hold a reunion dinner at the St. Francis Yacht Club, San Francisco, June 15.

American Rheumatism Association.—The annual meeting of the American Rheumatism Association will be held at the University of California Hospital, San Francisco, June 13. The preliminary program lists the following speakers:

- Dr. Morse J. Shapiro, Minneapolis, Differential Diagnosis of Rheumatic and Nonrheumatic Muscle Pains in Children.
- Dr. Mark P. Schultz, Washington, D. C., Metabolic Factors in the Induction of Nonpurulent Carditis.
- Dr. Daniel Murray Argenive, New York, Immunological Observations on Experimental Streptococcus Arthritis in Rabbits.
- Dr. Walter Bauer, Boston, Treatment of Gonorrheal and Rheumatoid Arthritis with Sulfanilamide.
- Drs. Keene O. Haldeman and Ralph Soto-Hall, San Francisco, Neuro-pathic Joint Disease.
- Drs. Stacy R. Mettler and Charles S. Capp, San Francisco, Neurologic Symptoms and Clinical Findings in Patients with Cervical Degenerative Arthritis.
- Dr. David H. Kling, Los Angeles, The Structure and Function of Synovial Membrane.
- Dr. John Albert Key, St. Louis, Experiences with Gold Salts in the Treatment of Chronic Arthritis.
- Dr. John D. Currence, New York, Hydrotherapy in Osteo-Arthritis.

Dr. William J. Kerr, San Francisco, will deliver the presidential address on "Radiculitis Associated with Spinal Arthritis."

American Psychiatric Association.—The ninety-fourth annual meeting of the American Psychiatric Association will be held at the Hotel Fairmont, San Francisco, June 6-10. Included among the speakers will be:

- Drs. Mona Spiegel-Adolf and Herbert Freed, Philadelphia, Effect of Metrazol Convulsions on Cerebrospinal Fluids.
- Drs. C. Penfield and Edwin B. Boldrey, Montreal, Canada, The Conditioning Effect of Epileptic Seizures upon the Human Cerebral Cortex.
- Dr. Eugene Ziskind, Los Angeles, The Inadequacy of Present Day Evidence Favoring a Hereditary Predisposition in Epilepsy.
- Dr. Frederick H. Allen, Philadelphia, Homosexuality: An Attempt to Solve the Problem of Human Difference.
- Dr. Lydia G. Giberson, New York, Pitfalls in Industry for the Psychiatrist.
- Drs. Abraham Myerson, Leo Alexander and Merrill Moore, Boston, Alcoholic Avitaminosis—A Practical Plan for Prevention.
- Dr. Andrew L. Skoog, Kansas City, Mo., Bromide Intoxication Involving Brain and Skin.

Special features include an informal round table dinner meeting of the Section on Convulsive Disorders and the American Chapter of the International League Against Epilepsy and the annual dinner Wednesday evening, when Dr. Ross McC. Chapman, Towson, Md., will deliver his presidential address. There will be round table discussions and special consideration given to such topics as Psychiatric Aspects of General Medical Problems, The Juvenile Delinquent and The Adult Criminal. There will also be a symposium on psychiatric education.

Academy of Tuberculosis Physicians.—The American Academy of Tuberculosis Physicians will meet at the Mark Hopkins Hotel, San Francisco, June 17-18. Dr. Jay A. Myers, Minneapolis, will deliver the presidential address. The tentative program lists the following speakers:

- Drs. O. Jovevius Farness and Charles W. Mills, Tucson, Ariz., A Case of Fungus Coccidioides Infection Primarily in the Lung with Cavity Formation and Healing.
- Dr. John M. Nicklas, Valhalla, N. Y., The Tuberculous Child.
- Dr. James M. Odell, The Dalles, Ore., The Blood Sedimentation Rate as an Index in the Treatment of Pulmonary Tuberculosis.
- Dr. Willis S. Lemon, Rochester, Minn., The Reaction of the Tissues of the Body to Infection with Tuberculosis Bacilli.
- Dr. Harry J. Corper, Denver, Simple Methods of Growing Tubercle Bacilli with Practical Applications for the Diagnosis and Biological Preparation.
- Dr. Frederic Maurice McPhedran, Philadelphia, Normal Borderline and Certain Conditions Commonly Overlooked.
- Dr. Philip J. Hodes, Philadelphia, The Healthy Chest and the Modifying Influences of Silicosis and Silicosis with Infection.
- Dr. William Edward Chamberlain, Philadelphia, Early Cancer.
- Dr. Sherwood Moore, St. Louis, The Use and the Advantage of the Tomograph.
- Dr. Maxim Pollak, Peoria, Ill., Results of Effective Tuberculosis Control.
- Dr. Philip T. Y. Ch'iu, Peiping, China (subject not announced).

A symposium on compression therapy will also be presented by Drs. Jane Skillen, Olive View, Calif.; Jacob W. Cutler, Philadelphia; Harold Brunn, San Francisco, and Ralph C. Matson, Portland.

Special Society Elections.—Dr. Lee M. Hurd, New York, was named president-elect of the American Laryngological, Rhinological and Otolological Society at its annual meeting in Atlantic City April 27-29. Dr. Harold I. Lillie, Rochester, Minn., became president and the following were elected vice

presidents: Drs. Frederic G. Sprowl, Spokane, Wash.; Francis E. Le Jeune, New Orleans; Thomas R. Gittins, Sioux City, Iowa, and Frank E. Kittredge, Nashua, N. H.—Dr. Harold Brunn, San Francisco, was named president of the American Association for Thoracic Surgery at its annual meeting in Atlanta April 5; Dr. Adrian V. S. Lambert, New York, was elected vice president, and Dr. Richard H. Meade Jr., Philadelphia, reelected secretary. The next annual session will be in Los Angeles.—The Eastern Surgical Society, whose membership includes surgeons of Eastern states, held its annual meeting in Richmond April 22-23. Dr. John P. Bowler, Hanover, N. H., was elected president and Dr. Maxw. Harbin, Cleveland, was reelected secretary. The 1939 meeting will be in Hanover, N. H.

CANADA

Summer School Clinics.—The annual summer school clinics of the Vancouver Medical Association will be in Vancouver June 21-24. Lectures will be delivered at the Hotel Vancouver in the mornings and evenings and clinics will be held at local hospitals. The tentative program lists the following speakers:

- Dr. Ray F. Farquharson, Toronto (subject not announced).
- Dr. Andrew Hunter, Toronto, The Edinburgh School of Medicine: Historic Notes and Personal Recollections.
- Dr. Oliver Ormsby, Chicago, Precancerous Dermatoses; Cutaneous Syphilis.
- Dr. Roy Glenwood Spurling, Louisville, Ky., Low Back Pain, Painful Arm and Shoulder and Intractable Pain.
- Dr. Waltman Walters, Rochester, Minn. (subject not announced).

Canadian Medical Association Meeting.—The sixty-ninth annual meeting of the Canadian Medical Association will be held at the Nova Scotian Hotel, Halifax, June 20-24, under the presidency of Dr. Theodore H. Leggett, Ottawa. The Medical Society of Nova Scotia will act as host. Sir Humphry Rolleston, Bart., Surrey, England, will deliver the Osler Lecture, Wednesday morning, on "Osler, the Last Phase, and His Influence on Medicine." There will be symposiums on poliomyelitis and streptococcal sore throat. Physicians from the United States included on the program are:

- Dr. Alfred W. Adson, Rochester, Minn., Spinal Cord Tumors.
- Dr. Frederick C. Irving, Boston, Observations on One Thousand Preeclampsies.
- Dr. Lincoln F. Sise, Boston, The Selection of the Anesthetic.
- Dr. Emery A. Roventine, New York, Anesthetic Complications Arising from Reflex Reactions During Abdominal Surgery.
- Dr. Richard Schatzki, Boston, Gastrointestinal Diagnosis.

FOREIGN

British Medical Association.—The one hundred and sixth annual meeting of the British Medical Association will be held in Plymouth July 15-22. The scientific part of the program will be presented in seventeen sections July 20-22. Sir Robert J. Johnstone, Belfast, is president of the association and Dr. Colin D. Lindsay, Plymouth, is president-elect.

Prize for Encephalitis Research.—The University of Bern, Switzerland, directs attention to the prize of 1,000 Swiss francs offered each year for work on lethargic encephalitis that signifies real progress in the diagnosis or treatment of the disease. Those who wish to participate in the competition should send their application to the dean of the Medical Faculty, University of Bern.

Psychoanalytic Journals Cease Publication.—An importer of foreign periodicals and books has reported to these headquarters that the *Internationale Zeitschrift für Psychoanalyse* and the journal *Imago*, the official organs of the International Psychoanalytic Society, have ceased publication. The editor of both of these journals was Sigmund Freud. The *International Journal of Individual Psychology* also will suspend publication. It is planned to issue a news bulletin, which will occasionally contain an article.

Dr. Wu Lien Teh Retires.—Dr. Wu Lien Teh, for thirty years in the health and medical services of the Chinese government, recently retired to his home in Penang. Dr. Wu graduated from Cambridge University, England, and after a short period of private practice was called into service by the imperial government during an epidemic of pneumonic plague in Harbin, Manchuria, in 1910. After the epidemic Dr. Wu was made director of the Manchurian Plague Prevention Service, a position he retained until 1932. In 1930 the republican government appointed him first director of the National Quarantine Service. He was editor of the *National Medical Journal*, now the *Chinese Medical Journal*, for fifteen years. He was a founder of the National Medical Association in 1914, was its secretary the first year and was later president. He has received honorary degrees from many learned bodies, including Johns Hopkins University.

Plans for Food Control in War Time

The report of the food (defense plans) department of the Board of Trade has just been published. Plans are being prepared on the assumption that complete control of food supplies and prices may be necessary. If rationing should become necessary, every person will be supplied with a ration book entitling him to purchase certain quantities of meat, sugar and butter during specified periods. In view of the possibly serious dislocation of trade, plans are being prepared to prevent any temporary shortage of food or rise in prices. The first step would be to requisition stocks of food in the hands of merchants and cargoes on arrival at ports. In releasing stocks, priority would be given to the defense services. The food controller would make arrangements for buying oversea supplies. In the final stage of distribution the retailer, registered with his food control committee, would have delivered to him at authorized prices the weekly supplies required to meet the needs of his regular customers. Prices would be fixed. The meat canners of the country are furnishing particulars of their output and storage capacity, so that full information may be available for the coordination of the production and distribution of their products. It may be necessary to ration bacon and ham at the outset, and arrangements for this are being made with the leading importers and distributors. The possible results of an air attack in interfering with importation and distribution of supplies have given rise to plans for such a contingency. Great Britain has been divided into fifteen areas, apart from London and the home counties, for each of which a divisional officer and nucleus of a staff have been appointed. The administration of food control will be entrusted to 1,500 local authorities. Work on food storage is being done. The government has bought for storage a large supply of wheat, sugar and whale oil.

The Problem of Working in Gas-Protective Clothing

During air raids, men engaged in decontamination and other anti-gas work have to wear protective impervious oilskin clothing. This has the disadvantage of impeding the escape of heat and water vapor from the body and so producing incipient heat stroke. Recently at the Royal Society of Medicine a speaker said that he had seen strong men wearing this clothing taking part in anti-gas exercises, and they were not able to carry on for more than a few minutes, as they found themselves disabled. Attempts have been made to remove the saturated air by pumping in fresh air at one end of the suit and out at the other but the method was not practical. In the *Journal of the Royal Army Medical Corps*, Dr. G. P. Crowden of the London School of Hygiene and Tropical Medicine reports experiments on the control of body temperature during muscular work in gas-protective clothing, which have solved the problem. He discovered that if wet cloths are applied to the outside of protective oilskin garments the impending heat collapse was averted. He then tested the effect of a water-retaining garment of khaki drill worn over the single piece protective suit. He found that despite the weight of the additional clothing the loss of body heat from evaporation was continuous and that the subject was able to carry on work in a very warm environment without discomfort. Dr. Crowden next tried bringing the cooling wet surface even closer by giving a wettable external fabric facing to the protective layer, which had the advantage of limiting the required clothing to one suit. A jacket, trousers and hood made of rubber was faced externally with an absorbent fabric moistened with water. In this apparel the subject worked well.

But it seems doubtful whether it would be as effective in protection against mustard gas. Dr. Crowden's first results obtained on young laboratory assistants were so good that they were tried in an officers' training camp. It was again found that, when the outer surface of clothing is maintained wet during muscular work, accumulation of body heat is prevented, sweating is much reduced and the danger of heat collapse, even under hot summer conditions, is removed.

Traveling Fellowships in Medicine

The Medical Research Council has invited application for six Rockefeller medical fellowships. They are intended for British graduates who have had some training in research work in clinical medicine or surgery or some other branch of medical science and who are likely to profit by a period of work at a center in the United States or elsewhere abroad before taking up positions for higher teaching or research at home. The stipend will be at the rate of \$1,800 a year for a single fellow and \$2,400 for a married one. Traveling expenses and some other allowances will be paid in addition. The council also offers four research fellowships in tuberculosis, which give special opportunities to those who intend to devote themselves to research in curative or preventive treatment.

Twins Born in the Air

A race against time was lost by an air pilot who was bringing an expectant mother from the islands on the west coast of Scotland, known as the outer Hebrides, to the Glasgow Maternity Hospital. Complications had arisen in her confinement and the medical authorities asked for an air ambulance to take her to the hospital. She gave birth to stillborn twins in midair.

Extrapleural Pneumothorax

There is a tendency in Paris to attempt to replace the classic intrapleural method of artificial pneumothorax in the treatment of pulmonary tuberculosis by an extrapleural operation. At the April 1 meeting of the Société médicale des hôpitaux Dr. Pierre-Bourgeois and his co-workers, submitted a report of twenty-five cases in which the extrapleural method had been employed. Attention was called to the fact that it is a difficult surgical procedure so far as technic is concerned and that the postoperative care is much more complicated than that of the older method. One of the twenty-five patients died four days after operation, the clinical picture being that of cardiac insufficiency. In two cases an infection of the extrapleural space occurred which required a great deal of care before recovery occurred six weeks after the operation. In a fourth patient, convalescence was complicated by the formation of a bronchocutaneous fistula. In the twenty-five cases there were five failures, seven mediocre results and thirteen in which the immediate result is favorable. The indications for extrapleural pneumothorax, in the opinion of Pierre-Bourgeois and his co-workers, are recent lesions in patients below the age of 40 years. The operation should be undertaken only if the patient is in good condition, but it can be used even when the pulmonary tuberculous lesions are in a moderate state of evolution. The extrapleural method can be used simultaneously with the intrapleural, the two cavities being separately filled with air.

Dr. Léon-Kindberg stated that not enough cases of extrapleural pneumothorax had been reported to serve as a basis for an opinion of its value. It is impossible at present to say how long the extrapleural pneumothorax will last. This opinion was shared by Professor Rist. Dr. Etienne Bernard also was skeptical regarding this newer method and maintained that it should be employed only if the older intrapleural method had

not given satisfactory results. The results when the extrapleural method is used are not good if cavities with very thick walls exist. This method is contraindicated when a cavity is located close to the chest wall.

Procaine Injection and Early Mobilization of Fractures

In the *Presse médicale*, June 12, 1937, Prof. René Leriche called attention to the excellent results obtained by blocking the vasomotor reflexes which have their origin at the seat of a fracture. These reflexes, in his opinion, largely cause the pain, edema and functional disability. At the April 6 meeting of the Académie de chirurgie of Paris, Professor Leriche read a paper in which he stated that after two or three injections of a solution of procaine hydrochloride at the seat of fracture and after an interval of two or three days there is such a complete relief from pain that the patient moves the limb as if it were not fractured. Such early voluntary movements seem to be followed by consolidation at a much earlier period than when the limb is immobilized.

This method has been employed in fractures of the olecranon and patella in which there is no separation of fragments and in fractures of the condyles of the humerus. It has also given satisfactory results in fractures of the upper end of the humerus and lower end of the radius in the aged and, after reduction, in fractures of the scaphoid and clavicle. Slides were shown by Professor Leriche illustrating the ability to secure early painless movements of the shoulder joint in elderly persons with fracture of the surgical neck of the humerus.

Procaine injection and early mobilization of fractures have been employed by Professor Leriche frequently during the past ten years. This technic was first described by Dr. Albert of Liège, Belgium, following experiments on animals in 1924, but Leriche had employed it independently in the clinic since 1920.

Opening of Emergency Hospital Near Center of Paris

The number of automobiles in Paris has increased from 155,400 in 1925 to 247,000 in 1937. There has been a corresponding increase in the number of automobile accidents. In 1925 there were 160 deaths and 2,607 severely injured from this cause, as compared to 246 deaths and 1,748 severely injured in 1937.

The various public hospitals of the department of the Seine, in which Paris is situated, have twenty-nine surgical services which receive emergency cases. One of the largest of these hospitals, the Beaujon, which had been located in the center of Paris, was recently transferred to a suburb, to the only eleven story structure for hospital purposes in Europe. To take care of accident cases formerly sent to the Hôpital Beaujon, a smaller one of about 120 beds, the emergency hospital Marmottan, was opened about a year ago. As soon as first aid has been given or urgent operations have been performed, the patients are transferred to one of the larger public hospitals. The construction and equipment of the new emergency hospital complies with all modern requirements.

Cases of Syphilis Resistant to Arsenical Treatment

An inaugural thesis by Dr. F. Goulenc, who had served a four year internship at the Hôpital St. Louis, cutaneous and venereal disease center of Paris, is of interest to syphilologists. All degrees of arsenoresistance are encountered, from cases in which there is partial or complete resistance to those in which the administration of arsenical preparations appears to activate the disease. Resistance to arsenical preparations can exist alone or be associated with a similar resistance to bismuth or mercury compounds. Eighteen per cent of all patients with syphilis were found to do better when treated with nonarsenical preparations. The frequency of negative Wassermann reactions in arsenoresistant cases was striking, the test changing to a posi-

tive one when bismuth compounds, which cured the lesions, were given. Experimental studies and certain clinical observations have shown that resistance to arsenical preparations is due to a special type of spirochetes which can be differentiated from the ordinary type. One has the impression that the absence of certain changes which the arsenical preparations usually undergo in the body best explains the resistance in certain cases. In addition, other factors have a secondary part, such as inadequate phagocytic reaction and lack of formation of antibodies.

From the therapeutic point of view, when cases of arsenoresistance are encountered it is advisable to try bismuth preparations first, and then other antisyphilitic preparations such as gold salts or potassium iodide. If these do not succeed in overcoming the resistance to all drugs, one should resort to auto-hemotherapy, proteinotherapy and pyretotherapy.

Another way to overcome arsenoresistance is to give arsenical preparations in strong doses at short intervals. Small doses are apt to develop a progressive resistance, on the part of the spirochete, to arsenical preparations. Mixed treatment, i. e., the simultaneous administration of arsenic and bismuth compounds or one of these and preparations of mercury, is to be discarded in favor of alternate periods in which only one of the foregoing is given. Bismuth compounds should be given only after the patient has received a minimum of 0.9 Gm. of neoarsphenamine, whereby the results of the administration of each preparation can be judged.

The Great Increase in Diphtheria

The fourfold increase in the German reich in the number of reported cases and deaths of diphtheria in the last ten years has given the disease an unprecedented notoriety. While no explanation is forthcoming, it is probably based on a wave-like fluctuation in incidence of the infection. The accompanying figures, based on reports of the sanitary police, show the greater morbidity of diphtheria within the last twelve years.

Occurrence of Diphtheria, 1926-1937

Year	No. of Cases	Fatal Cases
1926	30,300	1,500
1927	33,900	1,900
1928	46,900	2,700
1929	50,500	3,500
1930	70,500	4,500
1931	57,800	3,400
1932	65,400	3,300
1933	77,300	4,100
1934	119,100	5,500
1935	133,800	6,300
1936	147,000	5,600
1937	146,700	5,400

The increase since 1934 is particularly remarkable. Fortunately the disease appears to have assumed a less severe character, for the mortality has not kept pace with the morbidity. This conclusion is not altogether convincing, since medical measures can be effective even in grave cases. Morbidity has exhibited great regional variation, but the mean morbidity for the reich during the last three years was fairly consistent: 20 per 10,000 of population in 1935, 22 in 1936 and 21.8 in 1937.

The recession in the mortality of diphtheria within the last three years is a sign of the diminishing severity of the disease. It would be premature to say that the epidemic has been conquered or that the peak is past. Dr. Tornau points out in the *Deutsches Arztblatt* that the most recent data for 1938 already threaten to offset the small decline of 1937. In the current year, until February 19, a considerable increase over the corresponding weeks of 1937 has been reported. In 1935, 82.3 per

cent of diphtheria cases were among children between the ages of 2 and 14 and only 8.2 per cent were among adults over the age of 21. The campaign against diphtheria thus presents a grave problem.

The Age Distribution of the Medical Profession

The Central Organization of German Physicians has just released statistics for 1937 on the distribution of German doctors according to age. The year of birth of the youngest doctors was 1912; the oldest doctor was 97. There were nine living doctors over 90 years of age. The percental distribution

Distribution of Physicians According to Age

Age	Percentage	Age	Percentage
25-30.....	16.4	61-65.....	6.5
31-35.....	11.	66-70.....	5.1
36-40.....	14.	71-75.....	3.8
41-45.....	14.6	76-80.....	1.4
46-50.....	12.5	81-85.....	0.4
51-55.....	7.3	Over 85.....	0.1
56-60.....	6.9		

according to five year age groups is shown in the accompanying table. More than half the physicians in Germany (around 56 per cent) were between the ages of 25 and 45. The age distribution of the insurance practitioners differed from that of the profession as a whole, chiefly because young doctors who have just been licensed are not admitted to the panel practice. (About 56.2 per cent of all practitioners were eligible for panel practice.) The greater age of the insurance doctors as a group also depends somewhat on the greater time spent in special training and in general clinical training by many of them. Only 10.2 per cent were under 36 years of age; the majority (54 per cent) were from 36 to 50 years of age. Enumeration was made also of practitioners regarded as public officials and employees. In this group were included the medical officers of the defense forces. The entire number of doctors in public service was about 15,500; namely, 28 per cent of the entire profession. Doctors who held assistantships or similar posts in the medical schools came under this classification. About 70 per cent of doctors in public service were between 25 and 35 years of age and a further 20.9 per cent between 36 and 50 years of age. Accordingly, the number over the age of 50 was proportionately small (9 per cent).

Sex of the Newborn

After the World War an increase in the normal excess of newborn boys over girls was noted. The old observation that in time of war the normal excess of newborn males tends to increase was verified during the late war in every belligerent country in Europe. For Germany the rate of male excess reached a high of 108.5 boys to 100 girls in the year 1919, whereas during the years from 1876 to 1913 it had fluctuated between 105.6 and 106.6 to 100. But, although among other of the World War belligerents the ratio had resumed its peacetime norm by 1924, the prewar levels were not regained in Germany, Italy and Hungary. Dr. G. Heydel has published a study of this phenomenon in the *Allgemeines Statistisches Archiv*. He advances the following bases for the continuation of the higher proportion in Germany: 1. First of all the proportion of first born among the newborn has become larger. Infants of primiparas are more likely to be male than infants of other mothers. Substantial statistical data support this assumption. 2. The proportion of parous married women between the ages of 25 and 35 has increased. This may also be a factor in the continued high ratio; however, the data exhibit regional variation within the German reich and hence cannot be considered conclusive. 3. The number of spontaneous miscarriages has been reduced through an increase in the number of induced

abortions as well as through better facilities for advice and care of the pregnant woman. As it is precisely in spontaneous miscarriages that male fetuses greatly preponderate, the continued high ratio of boys to girls among the newborn can in part be accounted for by the fewer miscarriages.

Professor Boas Is Dead

Prof. Ismar Boas, formerly of Berlin, renowned specialist in diseases of the gastroenteric tract, died in Vienna, March 15, aged 80. He settled at Berlin in 1882 as a practicing physician. At Ewald's suggestion he came to devote himself to the study of the physiology and pathology of the digestion and in 1886 had become established as the first German physician whose practice was limited to gastroenteric disorders. His work on the diagnosis and therapy of gastric disorders has appeared in a series of German editions and has been translated into many foreign languages. His work on intestinal disorders has been widely read. The debt of specialists in this field to Boas is incalculable. One need only mention his monograph (1914) on occult hemorrhages. Named for him are Boas's point and the Ewald-Boas test breakfast. He rendered valuable service as founder and editor of the *Archiv für Verdauungskrankheiten*. Despite his advanced age, Boas had endeavored to keep active in scientific work. Since 1933 he had resided in Vienna at the home of his pupil Walter Zweig.

AUSTRALIA

(From Our Regular Correspondent)

April 11, 1938.

Proposed National Insurance for Australia

The commonwealth government of Australia in the last few years has considered proposals to introduce compulsory insurance against the financial stress of sickness and disablement, and an early introduction of the legislation is anticipated. Complete details of the proposed schemes are not yet available; British experts have delivered reports to serve as a basis, but it remains to adapt these to the Australian environment. Australian governments have provided a wide variety of social services. Great Britain, however, spends much more per head on social services than does Australia. Since the inauguration of the commonwealth there has been a steady upward movement in government expenditure, but the expenditure on social services has increased still more rapidly, as the accompanying table shows. Not only has the proportion of government expenditure on social services expanded; the proportion of social service expenditure to the national income has increased nearly threefold in a quarter of a century. If figures of expenditure from loan moneys for school building, housing and other social services were included, the upward movement would be still more striking.

The term "social services" at present includes such services as education, unemployment relief, hospitals, and old age and invalid pensions. The movement in the expenditure of pensions is interesting. In 1909, when they were instituted, the maximum pension was 10 shillings (\$2.50) a week. In 1909 there were 65,500 pensioners drawing a total of £1,500,000 (Australian currency). Today the maximum pension is £1 (\$5) a week. For the financial year 1936-1937 some 300,000 old age and invalid pensioners received a total of £14,000,000. The proportion of pensioners to total population will probably continue to grow for many years, as the decline in the growth of population brings a rising percentage into the pensioner age group. Thus every year tends to place an increasing burden on the shoulders of the remaining productive members of the community. There are no indications that the rate of increase of expenditure on social services is likely to slacken. Australia spent on social services about £5.16.0 (Australian currency) per head in 1935-1936, compared with £9 sterling per head spent by Great Britain in 1934. But part of the British expen-

diture was in the form of national insurance benefits, much of which was paid by contributions from the insured persons themselves. It seems that, if social services are to be developed in Australia, the insurance method will have to be used.

The government has sought advice in establishing social insurance on a national scale from two British officials, Sir Walter Kinnear of the Ministry of Health and Mr. Godfrey Ince of the Ministry of labor. Both have submitted reports outlining schemes which they consider suitable in Australia. The Kinnear scheme is for health and pensions insurance; Mr. Ince's is for unemployment insurance. The two schemes follow the British model in providing for contributions by employers, workers and the state. Sir Walter Kinnear's proposed scheme closely resembles that now operating in Great Britain—a compulsory contributory scheme with equal contributions by employers and workers, supplemented by a state subsidy. In return for his contribution a worker would receive the right to medical attention and sickness payments and to pension payments for himself. The scheme is designed to cover persons earning less than £365 per annum and all manual laborers. Health insurance for dependents of workers is not recommended, although friendly societies in this country are

Australian Social Provision and Total Expenditure

Year Ended June 30	Social Expenditure: (£1,000,000 Australian Currency)	Total Expendi- ture from Consolidated Revenue: (£1,000,000 Australian Currency)	Proportion of Social Expenditure to Total Expenditure from Consolidated Revenue, per Cent
1910	6.0	42.9	14.0
1914	9.5	62.0	15.3
1918	12.0	84.0	14.3
1921	18.3	139.4	13.1
1925	21.6	157.8	13.7
1930	32.5	185.2	17.5
1931	38.0	187.7	20.2
1932	39.0	179.3	21.8
1933	35.8	170.2	21.0
1934	33.6	168.4	20.0
1935	34.2	173.6	19.7
1936	37.2	179.2	20.8
1937	39.3	186.0	21.1

accustomed to provide medical benefits for both the bread winner and his dependents. The introduction of the proposed health scheme would mean a departure from the existing administrative practice of Australian governments in that voluntary private organizations would be used for the purpose of public administration. Sir Walter suggests that detailed administration of the scheme, other than medical benefits, should be in the hands of "approved societies"—mutual benefit associations of insured persons. These societies would include organizations already experienced in the administration of insurance benefits and also "any reputable body of persons" who cared to form a society. Each society would be self governing, keeping its own set of books but subject to periodic inspection. Persons to be insured under the scheme could choose their own society; societies could not reject applicants solely on the ground of age. Medical benefits would be under the direct supervision of the central department in consultation with a "medical benefits council" including representatives of insured persons, medical practitioners, chemists, local authorities and persons appointed by the minister. Certain of the benefits under the scheme would be statutory and available to all insured persons; others would be "additional"—contingent on the achievement of a good sickness and administrative record by the individual societies. Every society would be treated as a separate insurance unit, though this is inconsistent with the principle that the insurance unit should be as large as possible. The introduction of health insurance will give an opportunity

for planning a comprehensive long range scheme to promote public health. Statutory benefits already recommended in the Kinnear plan are "medical," including free medical treatment and the supply of drugs and medicines; "sickness," which is a money payment during incapacity to work through illness, and "disablement," corresponding to the present invalid pensions. While no recommendation has been made for the treatment of dependents, the welfare of women and children is so vital that a scheme which fails to care for them must be open to serious doubt. Also there are definite advantages in the inclusion of dental and optical treatment and hospital service for which insured persons might consider it worth while to pay extra. As soon as funds permit, another field is that of specialist treatment.

National Insurance for New Zealand

New Zealand is on the point of adopting a national insurance scheme. The government's social security plan was submitted this week to a special parliamentary committee for examination. Proposals for the committee's consideration are: 1. To establish a national health service to ensure for all persons ordinarily resident in New Zealand adequate medical, surgical, pharmaceutical, dental, hospital, nursing and other treatment, including a nursing domestic help service to provide skilled assistance in homes during illness. 2. To establish a national superannuation service to assure residents an adequate income when they become unable to support themselves through old age, infirmity, sickness or other disabilities or widowhood. The legislation and experimentation of the labor government in New Zealand has attracted worldwide interest. Recently Sir Henry Gullet, former minister for customs in Australia, visited New Zealand. He writes: "The government is making a very gallant effort to set up in New Zealand an economic paradise in the South Seas. No one can doubt the idealism and sincerity of the prime minister and his colleagues. Their courage is sublime, their indifference to orthodox practice and precedent magnificent. They not only bay at the moon but are completely satisfied in their own minds that already they have gone far toward reaching it."

Organization for the Control of Cancer

The ninth Australian Cancer Conference is being held in Sydney, New South Wales. More than 100 delegates from Australian universities and other bodies for the control of cancer are attending, and representatives of similar organizations in New Zealand are taking part. The increase in cancer has led to the development of a national organization directed toward the control of this disease. Treatment centers equipped to carry out investigation and treatment have been formed at the principal hospitals. Ten Gm. of radium, purchased in 1928 by the commonwealth government, has been distributed on loan to the treatment centers. Treatment is available to all irrespective of ability to pay. Cooperation is maintained between research workers, physicists and biochemists and the medical men engaged in the clinical investigation and treatment of the disease. At Melbourne University the commonwealth government maintains a radium laboratory for the production of radon for use in treatment, for the construction and repair of radium apparatus and for research into problems of treatment. During 1936 a total of 40,221 millicuries of radon was issued by this laboratory and used in the treatment of cancer and the carrying out of research. This represents an increase of 38 per cent on the output for the previous year. Local services in relation to the use of radium and x-rays have been or are being developed in the capital cities of the several states.

The Advisory Council on Nutrition

During 1935, Australian delegates to the Assembly of the League of Nations and the International Labor Conference were largely instrumental in inspiring a concerted international inquiry into worldwide problems of nutrition. Australia in

1936 appointed a commonwealth advisory council on nutrition, under the chairmanship of the director general of health and composed of experts representing health and agricultural interests, the Commonwealth Council for Scientific and Industrial Research, the university medical schools and the practicing medical and dental professions. The initial inquiries of this council were framed to enable advice to be given to the government on two principal aspects of the problem: (a) the present state of nutrition of the Australian people and (b) the nature of any evidence that the Australian people are in any degree undernourished or that their diet is improperly balanced. These inquiries have proceeded along two main lines: a survey of household dietaries in Sydney, Melbourne, Brisbane and Adelaide and a survey of the nutritional state of children in inland areas. The statistical compilation of the records obtained and parallel work of chemical analysis are being carried out by a special technical staff at the School of Public Health and Tropical Medicine, Sydney. The local organization of the inquiry has been furthered by the appointment of state committees. The two sections of the Australian population showing most markedly the effects of malnutrition are the children living in the far inland areas and the poorer sections of the community in the city.

April 12, 1938.

Meeting of Gastroenterologists

The Società di gastroenterologia met at Rome under the presidency of Prof. Cesare Frugoni, medical clinician. Professor Scimone read a paper on the value of the Takata-Ara test, which he has used in 150 cases of disorders of the liver. In many instances the clinical diagnosis was confirmed by radiologic observations. If cirrhosis was present the Takata-Ara reaction was always strongly positive. The reactions were often positive in icterus based on chronic stasis of long standing, acute atrophy of the liver and destruction of the hepatic parenchyma. The author says that the Takata-Ara test, although not absolutely specific for cirrhosis, is a valuable diagnostic aid in the field of hepatopathy. The simplicity of the test justifies its widespread use. Yet the Takata-Ara reaction is inferior as a diagnostic test to some other tests; e. g., the galactose tolerance test and the rose bengal test.

Ascarelli talked on the x-ray visualization of intestinal intussusception. Ileocolic intussusception in which the cecum, uninvolved, remains intact is rather uncommon; the colocolic form is rare and only eleven cases are recorded in the entire literature. The roentgenologic examination is carried out after the administration of barium sulfate orally or by rectum. Both direct and indirect evidence of invagination may be revealed. Indirect indications of intussusception are dilatation of the segment of the bowel with peristalsis from stenosis of the lumen, non-visualization of the bowel segment that corresponds to the invaginated portion, and stasis of the barium in the upper segment of the intestine with normal filling of the distal portion. Moreover, either the intussusceptum or the intussusciens may be visualized in the roentgenogram; this constitutes direct evidence of the process. An intussusceptum appears as an arcuated, filiform image; an intussusciens is visualized as a persistent shadow in the form of a physharmonica, resulting from the retrograde accumulation of barium about the invaginated segment.

Marini submitted a study of ileocecal tuberculosis. He said that the absence from the roentgenogram of the normal shadow of the opaque meal in the ascending cecocolon, although formerly regarded as pathognomonic of specific disorders, can be encountered in various disease conditions. Accordingly, if this sign is to aid in the establishment of a more exact diagnosis it ought to be evaluated in relation to other roentgenologic data and

within the framework of the complete clinical picture. Among various circumstances that underlie this nonvisualization of the opaque meal (Stierlin's symptom, as it is called) there may be in addition to the organic lesions a nervous reflex element manifested in hypermotility and spasm. To verify the presence of Stierlin's symptom the test should be repeated several times at intervals of a few days. The barium should be administered both orally and by rectum. In cecal tuberculosis the rigidity of the ileocecal valve permits a reflux of the rectally introduced substance from the cecum into the ileum. He concludes that the Stierlin symptom, if well authenticated and if associated with other signs, permits a diagnosis of cecal tuberculosis even in previously nonsuggestive cases.

Ballatore submitted a discussion of the beneficial effects of hot and cold application to the epigastrium. He wished to determine whether the favorable influence could be traced to modifications of the gastric juice. He therefore investigated the gastric activity, using fractionated sounds, of twenty patients to whom ice bags had been applied and twenty-four patients to whom hot water bags had been applied. The induced variations in the curve of gastric secretion were observed to be slight and irregular regardless of the type of stimulus. The author therefore concluded that the therapeutic effect of the application was based on neurovascular factors.

Sebastianelli reported two rare cases of multiple cutaneous metastases transmitted by embolism. The primary disorders in these cases were respectively hypernephroma and gastric sarcoma. Metastases of this type have the following common characteristics: Men and women are equally affected, they are more likely to be manifested by persons over 40 years of age, they appear suddenly, their size varies from that of a grain of millet to that of a pigeon's egg; they are of firm consistency and may be seated in the cutis or in the subcutis. The processes are at first indolent, then undergo an extremely rapid development and may ulcerate. Their manifestation indicates an imminent fatal termination, which usually ensues within from sixty to ninety days.

Società Medico-Chirurgica

The Società medico-chirurgica of Bologna met under the presidency of Prof. Vittorio Putti. Dell'Acqua has experimented with new substances having a hypoglycemic action in the therapy of diabetes mellitus. In five normal subjects and twenty-seven diabetic patients he determined the course of the glycemic and glycosuric curves, thirty minutes and fifteen minutes following intravenous injections of 10 cc. of a 20 per cent solution of sodium dehydrocholate. Marked remission of the glycemia was noted in nearly all the diabetic subjects.

Marriages

GEORGE WINSLOW SIMPSON, Norfolk, Va., to Miss Virginia Frances Martin of South Norfolk, Va., April 7.

JACK THOMPSON FARRAR, Tullahoma, Tenn., to Miss Grace Elizabeth McKee of Faunsdale, Ala., May 1.

SOLOMON P. BIALOW, Waltham, Mass., to Miss Edith Ann Druker of Newton, at Boston, March 20.

JOHN B. ROTH, Morris, Ill., to Miss Sarah Lee Smith of Henderson, Ky., in Chicago, March 17.

EMIR ALLEN GAW, Columbus, Ohio, to Miss Elise Pumpelly Gregg of Waterbury, Conn., March 19.

JOHN KELLER OWEN, Charlottesville, Va., to Miss Frances Marshall Baker at Alexandria, May 7.

JAY E. HOULAHAN, Mason City, Iowa, to Miss Beulah Sanders of Creston, March 1.

JOHN H. SCHARF, New York, to Miss Thelma Bogart of Chicago, March 20.

VICTOR C. TILLMANNS to Miss Tone Kammann, both of Los Angeles, March 5.

Deaths

John Jacob Abel, professor emeritus of pharmacology at Johns Hopkins University School of Medicine, Baltimore, died, May 26, in the Johns Hopkins Hospital, aged 81. Dr. Abel was born in Cleveland, May 19, 1857. He was educated at the University of Michigan and Johns Hopkins University, and received the medical degree from the Université de Strasbourg Faculté de Médecine in 1888. He was lecturer and professor of materia medica and therapeutics at the University of Michigan from 1891 to 1893, when he joined the faculty of Johns Hopkins University in Baltimore as professor of pharmacology, holding the position for almost forty years, until he became professor emeritus in 1932. Dr. Abel had been director of the Laboratory for Endocrine Research at Johns Hopkins since 1932. He founded and was editor of the *Journal of Pharmacology and Experimental Therapeutics* from 1909 to 1932. He was president of the American Association for the Advancement of Science in 1932 and a member of the Association of American Physicians, the American Physiological Society, the Society for Pharmacology and Experimental Therapeutics and the American Chemical Society; honorary member of the Chinese Physiological Society, the Society for Biology (Buenos Aires) and the Pharmacological and Physiological Societies of Great Britain. The Chicago section of the American Chemical Society awarded Dr. Abel the Willard Gibbs Gold Medal for 1927. The choice was made by a jury of twelve chemists from the country at large, and Dr. Abel received a majority of votes cast on the first ballot. Dr. Abel's research was largely in the field of glandular extracts; his work made it possible to isolate epinephrine in pure crystalline form. He and his associates were the first to isolate insulin in crystalline form. He also was awarded the Research Corporation prize in 1925, the gold medal of the Society of Apothecaries, London, 1928, the Philip A. Conné medal of the New York Chemists' Club, 1932, and the Kober medal, 1934. He delivered the first Kober Lecture sponsored by the Kober Foundation under the auspices of the Association of American Physicians in 1925. Dr. Abel had been given honorary degrees by various universities and had been made a member of many other scientific organizations in this country and abroad. In 1927 he was further honored when the Chemical Foundation of New York granted to Johns Hopkins University about \$210,000 for an extensive research investigation on the cause and treatment of the common cold. The foundation requested that this fund be named the John Jacob Abel endowment for research.

Allen Buckner Kanavel ♂ professor of surgery at Northwestern University Medical School, Chicago, was killed, May 27, in an automobile accident near Mojave, Calif., aged 63. Dr. Kanavel was born in Sedgwick, Kan., Sept. 2, 1874. He received his bachelor of philosophy from Northwestern University in 1896, medical degree cum laude in 1899, and later studied abroad. In 1901 he was instructor of clinical surgery, assistant professor of surgery from 1908 to 1917, associate professor from 1917 to 1919 and since 1919 professor. He was chairman of the Section on Surgery, General and Abdominal, from 1930 to 1931, of the American Medical Association; past president, a regent and fellow of the American College of Surgeons; a member of the American Surgical Association, Western Surgical Association, Society of Clinical Surgeons and the Society of Neurological Surgeons. During the World War he served as a major in the medical corps and later was made a colonel. He was attending surgeon to the Wesley and Passavant hospitals in Chicago. Dr. Kanavel was the editor of *Surgery, Gynecology and Obstetrics*, a contributor to "Keen's System of Surgery," and to "Ochsner's System of Surgery" and to the periodical literature. He was the author of the well known book, "Infections of the Hand." In 1924 he received the honorary degree of doctor of science from Northwestern University.

Robert Tait McKenzie ♂ formerly director of the department of physical education at the University of Pennsylvania School of Medicine, Philadelphia, also a noted sculptor, died, April 28, of heart disease, at his home in Philadelphia, aged 70. Dr. McKenzie was born in Almonte, Ont., Canada, May 26, 1867. He received the degree of doctor of medicine in 1892 from McGill University, Montreal, Que. In 1895 he was house physician to the Governor General of Canada. From 1895 to 1904 he was demonstrator, then lecturer of anatomy, and from 1896 to 1904 he was medical director on physical training at his alma mater. He delivered the Olympic lectures at St. Louis in 1904, and from 1904 to 1930 was professor and director of the department of physical education at the University of Penn-

sylvania. During the World War he was commissioned temporary major in the Royal Army Medical Corps. Dr. McKenzie was particularly noted for portraits and medals in bas-relief, statues of athletes and memorials of the World War. He was the sculptor of the Franklin Statue at the University of Pennsylvania, the Scottish-American War Memorial at Edinburgh and the War Memorial in the Parliament Building at Ottawa. In 1912 he was awarded a silver medal from the king of Sweden for his bronze medallion "The Joy of Effort," fashioned in commemoration of the Olympic games at Stockholm, Sweden. He was the author of "Exercise in Education and Medicine," "Treatment of Convalescent Soldiers by Physical Means," "Reclaiming the Maimed" and was the editor of a series of textbooks on physical education.

Daniel H. McCalman, Winnipeg, Man., Canada; Manitoba Medical College, Winnipeg, 1899; in 1902 became professor of hygiene at his alma mater, in 1905 lecturer in obstetrics, and in 1907 professor of obstetrics, a post which he held for twenty years, then becoming professor emeritus; in 1905 was appointed obstetrician to the Winnipeg General Hospital and resigned in 1922, when he was appointed a member of the honorary consulting staff; formerly chairman of the provincial board of health; past president of the Manitoba College of Physicians and Surgeons; in 1930 became a member of the Sanatorium Board of Manitoba; aged 76; died, March 5, of cerebral hemorrhage.

Arthur Aloysius O'Neill ♂ San Francisco; Cooper Medical College, San Francisco, 1891; assistant clinical professor of medicine, emeritus, Stanford University School of Medicine; past president of San Francisco County Medical Society; assistant surgeon, Cooper Medical College Clinic, 1893; assistant in diseases of the skin, San Francisco Polyclinic, 1902-1907; in charge of Isolation and Plague Hospital, 1907-1910, of Isolation Hospital, 1912-1917; assistant, U. S. Public Health Service Laboratory, 1910-1912; formerly city physician; surgeon, U. S. Public Health Service, reserve and later consultant, communicable diseases; aged 68; died, March 2.

Francis Asbury Hulst ♂ Greenwich, N. Y.; Syracuse University College of Medicine, 1904; formerly instructor in bacteriology and pathology at his alma mater; at one time pathologist for the Brooklyn, Methodist Episcopal, St. Catherine's, St. Mary's and St. Christopher's hospitals, Brooklyn; for several years served as medical examiner for the city schools; aged 60; died, March 13, in the McClellan Hospital, Cambridge, of lobar pneumonia and arteriosclerotic heart disease.

Ernest Alexander Hunt, Des Moines, Iowa; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1898; member of the Iowa State Medical Society; on the staff of The Retreat; formerly on the staff of the Winnebago (Wis.) State Hospital; aged 62; died, March 4, of uremia, following an operation for carcinoma of the bladder.

John Donaldson Porterfield Jr., Cape Girardeau, Mo.; Rush Medical College, Chicago, 1897; fellow of the American College of Surgeons; formerly member of the board of education; on the staff of St. Francis Hospital; served during the World War; aged 61; died, March 10, in the Veterans Administration Facility, North Little Rock, Ark., of cerebral hemorrhage.

John Clarence Knight, Plant City, Fla.; University of Nashville (Tenn.) Medical Department, 1900; member of the Florida Medical Association; for many years health officer of Plant City; served during the World War as a member of a draft board; past president of the Hillsborough County Medical Society; aged 66; died, March 6, of coronary thrombosis.

William Henry Jacob, Paterson, N. J.; Columbia University College of Physicians and Surgeons, New York, 1902; member of the Medical Society of New Jersey; formerly member of the board of education; fellow of the American College of Surgeons; on the staff of St. Joseph's Hospital; aged 58; died, March 2, of illuminating gas poisoning.

George Hamilton Jenkins, Binghamton, N. Y.; New York Homeopathic Medical College and Hospital, New York, 1889; member of the Medical Society of the State of New York; fellow of the American College of Surgeons; consultant to the Binghamton City Hospital; aged 76; died, March 26, of cerebral sclerosis and bulbar paralysis.

Daniel Morton ♂ St. Joseph, Mo.; University of Louisville (Ky.) Medical Department, 1887; member of the American Proctologic Society; fellow of the American College of Surgeons; surgeon to the Missouri Methodist Hospital and proctologist to the welfare board of State Hospital number 2; aged 73; died, March 14, of septicemia.

John Daniel Kerr • Clinton, N. C.; University of Maryland School of Medicine, Baltimore, 1908; member of the county board of health; formerly county health officer; served during the World War; aged 53; died, March 16, in the James Walker Memorial Hospital, Wilmington, of injuries received in an automobile accident.

Hubbard Kavanaugh Hinde • San Angelo, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1915; fellow of the American College of Surgeons; member of the staffs of the Shannon West Texas Memorial Hospital and St. John's Sanitarium; aged 46; was killed, March 18, in an automobile accident.

Francis Irving Nettleton • Shelton, Conn.; Yale University School of Medicine, New Haven, 1897; past president of the Fairfield County Medical Society; formerly city health officer and mayor of Shelton; on the staff of the Griffin Hospital, Derby; aged 63; died, March 19, of cardiorenal vascular disease.

Miron Isaac Marsh • Cedarville, Ohio; Medical College of Ohio, Cincinnati, 1895; past president of the Greene County Medical Society; vice president of the board of trustees and for many years member of the board of trustees of Cedarville College; aged 72; died, March 20, of heart disease.

Leon A. Jacobus • Winfield, Kan.; College of Physicians and Surgeons of Chicago, 1893; aged 70; on the staffs of the William Newton Memorial Hospital and St. Mary's Hospital, where he died, March 20, of adenocarcinoma of the rectum, with obstruction and diverticulosis of the colon.

Leon Wade Martin • Chicago; University of Illinois College of Medicine, Chicago, 1917; associate in obstetrics and gynecology at his alma mater; served during the World War; on the staff of St. Joseph's Hospital; aged 47; died, March 6, of aplastic anemia and bronchopneumonia.

Louis H. Kirk, Austin, Texas; University of Texas School of Medicine, Galveston, 1903; member of the State Medical Association of Texas; on the staff of the Texas Deaf, Dumb and Blind Institute; aged 60; died, March 22, of acute dilatation of the heart, emphysema and pneumonia.

Curtis L. Lyon, Charleston, W. Va.; College of Physicians and Surgeons, Baltimore, 1915; member of the West Virginia State Medical Association; aged 64; died, March 20, in the Charleston General Hospital of carcinoma of the sigmoid with perforation and peritonitis.

Francis Abraham Longaker, Olympia, Wash.; Bennett College of Eclectic Medicine and Surgery, Chicago, 1906; member of the Washington State Medical Association; served during the World War; mayor of Olympia; aged 57; died, March 5, of coronary disease.

Frank Hubert Jett • Terre Haute, Ind.; Columbian University Medical Department, Washington, D. C., 1905; fellow of the American College of Surgeons; on the staff of the Union Hospital; aged 61; died, March 13, in St. Anthony's Hospital, of bronchiectasis.

Claude Edward McDermid • Niagara Falls, N. Y.; Georgetown University School of Medicine, Washington, D. C., 1908; on the staffs of the Memorial Hospital and Mount St. Mary's Hospital; aged 52; died, March 12, of coronary occlusion.

Samuel Meredith Janes, Marquette, Mich.; Hahnemann Medical College of the Pacific, San Francisco, 1888; Illinois Medical College, Chicago, 1902; aged 76; died, March 12, in the New Britain (Conn.) General Hospital of cerebral hemorrhage.

William Matthew Raymond, Pickwick Dam, Tenn.; Washington University School of Medicine, St. Louis, 1930; member of the Medical Association of the State of Alabama; aged 31; died, March 30, of a self-inflicted bullet wound.

Leonard Aaron Jaslow, New York; Eclectic Medical College of the City of New York, 1907; member of the Medical Society of the State of New York; served during the World War; aged 57; died, March 5, of cerebral hemorrhage.

Isaac William Howard, Maysville, Ala.; Memphis (Tenn.) Hospital Medical College, 1898; member of the Medical Association of the State of Alabama; aged 68; died, March 19, of coronary thrombosis, myocarditis and arteriosclerosis.

Thomas Lafayette Higginbotham, Creelsboro, Ky.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1906; aged 58; died, March 4, in Jamestown of cerebral hemorrhage.

Edward Loomis Pratt • Winsted, Conn.; University of the City of New York Medical Department, 1884; aged 79; on the staff of the Litchfield County Hospital, where he died, March 4, of prostatic adenoma.

Clarence C. Perry, West Rutland, Vt.; Dartmouth Medical School, Hanover, N. H., 1877; member of the Vermont State Medical Society; aged 88; died, March 22, in the Rutland Hospital of pneumonia.

Prince Albert Meneray, Santa Rosa, Calif.; Kentucky School of Medicine, Louisville, 1891; member of the California Medical Association; county health officer; aged 79; died, March 1.

John Crawford Hall, McPherson, Kan.; Kansas City (Mo.) Medical College, 1887; member of the Kansas Medical Society; aged 79; died, March 21, of heart block and arteriosclerosis.

Thomas E. Hughes, Camden, N. J.; Medico-Chirurgical College of Philadelphia, 1907; member of the Medical Society of New Jersey; aged 55; died, March 6, of coronary thrombosis.

Selig Clifton Frost, Memphis, Tenn.; University of Tennessee Medical Department, Nashville, 1899; aged 60; died, March 11, in the Baptist Hospital of carcinoma of the larynx.

Clarence Andrew Kerner, Phoenix, Ariz.; Milwaukee Medical College, 1910; formerly connected with the Indian Service; aged 58; died, March 4, of cerebral hemorrhage.

A. H. Jones, Whitewater, Ind.; Curtis Physio-Medical Institute, Marion, 1894; aged 68; was drowned, March 7, in the Gulf of Mexico off Brandenton, Fla., while fishing.

Edward Ebby Hethcock, Los Angeles; National University of Arts and Sciences Medical Department, St. Louis, 1917; aged 51; died, March 11, of cerebral hemorrhage.

Francis Marion Crume, Lamy, N. M.; University of the South Medical Department, Sewanee, Tenn., 1901; aged 74; died in March when struck by an automobile.

Charles A. Lenhard, Detroit; Detroit College of Medicine, 1890; member of the Michigan State Medical Society; aged 78; died, March 11, of chronic myocarditis.

Malcolm Thomas Moore, Sullivan, Ill.; College of Physicians and Surgeons of Chicago, 1885; aged 80; was killed, March 29, when struck by an automobile.

William Marion Powell, Atlanta, Ga.; Atlanta Medical College, 1883; aged 79; died, March 29, in a hospital at Charlotte, N. C., of prostatic hypertrophy.

Clarence H. S. Henderson, Greenwood, S. C.; Leonard Medical School, Raleigh, 1903; aged 61; died, March 11, of heart disease and pulmonary abscess.

Merton Carl Moss, St. Louis; St. Louis University School of Medicine, 1920; aged 41; died, March 20, in the Alexian Brothers' Hospital of pneumonia.

Owen William O'Neil, Mooers Forks, N. Y.; Baltimore Medical College, 1897; aged 65; died suddenly, March 10, of heart disease and gastric ulcer.

Arthur George Rawlings Nichol, New York; Bellevue Hospital Medical College, New York, 1897; aged 68; died, March 3, of arteriosclerosis.

Benjamin B. Peters, Christiana, Del.; Jefferson Medical College of Philadelphia, 1884; aged 75; was found dead, March 25, of a gunshot wound.

Henry William Hand, San Diego, Calif.; Bellevue Hospital Medical College, New York, 1890; aged 77; died, March 21, of diabetes mellitus.

Ernest Lee Hutchison, England, Ark.; Kansas City (Mo.) College of Medicine and Surgery, 1919; aged 54; died, March 3, of angina pectoris.

Frank Joseph Bedrick Kalal, Clarkson, Neb.; John A. Creighton Medical College, Omaha, 1901; aged 65; died, March 3, of angina pectoris.

Hugh Joseph McGee • Buffalo; University of Buffalo School of Medicine, 1907; aged 60; died, March 17, of coronary sclerosis.

R. Adlington Newman, Detroit; Detroit College of Medicine, 1889; aged 77; died, March 9, in the Harper Hospital of pneumonia.

Charles Andrew Moore, Springfield, Mo.; St. Louis College of Physicians and Surgeons, 1892; aged 72; died, March 7.

William Robert McCutcheon, Thorp, Wis.; Rush Medical College, Chicago, 1884; aged 80; died, March 19, of senility.

Albert LaFayette Johnson, Knoxville, Tenn.; Tennessee Medical College, Knoxville, 1893; aged 68; died, March 29.

Alfred A. McBrien, Arcadia, Calif.; St. Louis College of Physicians and Surgeons, 1898; aged 70; died, March 9.

Bureau of Investigation

MIDOL

The Product Is Changed, But the Name Remains

When one buys a "patent medicine," one buys a *name* and not a *thing*! The thing may change overnight, but the name, like Tennyson's brook, goes on forever. The "patent medicine" manufacturer builds up a property value, not in the *thing* that he puts out, but in the trade-marked name that he gives to his product. Should it be commercially expedient to change completely the composition of a "patent medicine," the average manufacturer of such products will not hesitate to make the change. But the public will be none the wiser until some independent investigator records the fact.

A "patent medicine" called "Midol" has been on the market for many years. It was one of the first of the nostrums sold direct to the public to depend, for its action, on the presence of aminopyrine, which was put on the market for physicians' use under the proprietary name "Pyramidon."

In THE JOURNAL, Aug. 10, 1912, the A. M. A. chemists showed that Midol depended essentially on Pyramidon (aminopyrine) for its therapeutic effect and contained, also, a small quantity of caffeine. The article commented that now that Pyramidon was being used as a "patent medicine," it was "probable that its toxicology will become better known." The prophecy has long since come true. To quote from New and Nonofficial Remedies (1938):

"Aminopyrine appears to produce serious and sometimes fatal granulocytopenia, especially in susceptible individuals . . . It should not be administered in large doses or over a long period of time unless repeated leukocyte and differential counts are made at regular intervals. *The drug should not be used in the treatment of dysmenorrhea or for any other purpose at or near the menstrual period.*" [Italics ours.—Ed.]

Yet Midol has been featured for many years past as "especially for the relief of functional menstrual pain and discomfort"! In spite of the fact that the dangerous potentialities of aminopyrine have been known for some years past, Midol continued to contain this drug.

In December 1936, the Food and Drug Administration seized a quantity of Midol, declaring that it was misbranded under the act. The manufacturers put up no defense, and in January 1937 the court entered judgments of condemnation and ordered that the seized product be destroyed. Notice of Judgment No. 26992, issued in July 1937, which described this case, stated that Midol contained a little less than 5 grains of aminopyrine and a little more than one third of a grain of caffeine to each tablet. The Notice of Judgment opened with this statement:

"This product was represented to be a safe and an appropriate remedy and to be harmless, non-narcotic, and non-habit-forming. Examination showed that it contained a drug that was deemed to be dangerous, which had narcotic or sleep-producing properties, and which might be habit-forming. The labeling also bore false and fraudulent curative and therapeutic claims."

The Federal Trade Commission in May 1937 reported that the General Drug Company, which puts out Midol, had entered into a stipulation with the Commission to discontinue certain false and misleading representations concerning the therapeutic value of Midol.

Another Notice of Judgment issued in April 1938 also declared that Midol seized in September 1937 still contained approximately 5 grains of aminopyrine to each tablet. It declared, also, that the packages still represented that Midol was a safe and appropriate remedy for the relief of functional menstrual pain and discomfort, headache and neuralgia, whereas, the government declared, "the article was not a safe and appropriate remedy when used as directed for the relief of such ailments, but was a dangerous drug." Here again the General Drug Co. made no defense and the court once more entered judgment of condemnation and ordered the seized product to be destroyed.

In 1937 the Bureau of Investigation of the American Medical Association was notified by an organization devoted to honesty

in advertising that the formula for Midol had been changed. A specimen of Midol was purchased on the Chicago market and subjected to tests in the A. M. A. Chemical Laboratory, which reported that aminopyrine still seemed to be the chief ingredient.

On April 20, 1938, the Bureau of Investigation wrote to the General Drug Company, stating that for some years the Bureau had been reporting to those who inquired about the product that Midol contained, for its essential drug, aminopyrine with small amount of caffeine, but that as it had been suggested that Midol no longer contained aminopyrine, the General Drug Company was asked whether it cared to state just what its present composition of Midol might be. On April 29 the General Drug Company replied:

"We are indeed pleased to reply to your letter of April 20th and to have an opportunity to advise you that Midol as now constituted does not contain aminopyrine."

"We will greatly appreciate your further assistance in passing this information along to interested parties who may inquire of you regarding our product."

This letter was acknowledged by the Bureau of Investigation, which expressed regret that the General Drug Company, while admitting that the composition of its product had been changed, and equally willing to say what their product did *not* contain, did not see fit to state what the new product *did* contain. No reply to this letter has been received.

A specimen of Midol was purchased on the open market in eastern Pennsylvania and submitted to the A. M. A. Chemical Laboratory for analysis. The chemists now report that tests indicate that these Midol tablets no longer contain aminopyrine but do contain caffeine and appear to have, for their most active ingredient, acetylsalicylic acid—*aspirin*!

The trade package of the new aspirin-containing Midol is identical with trade packages previously issued of aminopyrine-containing Midol. In other words, the public is given no information regarding the fact that the composition of Midol today is entirely different from the composition of Midol a year or so ago. When you buy a "patent medicine," you buy a name and not a thing.

When will public opinion demand a national law that will require manufacturers of "patent medicines" to declare the names and amounts of all drugs in their mixtures for which they make therapeutic claims?

Correspondence

ORAL IMMUNIZATION IN ALLERGY

To the Editor:—Ever since hypodermic medication has been used as substitution or immunization therapy, attempts have been made to replace it by oral administration. Naturally this should be our aim, since the ease of administration, lack of pain and possibly lower cost would make oral therapy more desirable. Oral immunization thus far with the majority of vaccines and specific antigens has not been accepted as successful. One of the newest forms of specific therapy of that type includes pollen. While some reports relative to the use of pollen orally were published fifteen years ago, in the last year or two the greatest attention has been given it. Several papers have dealt with the efficacy of pollen administered orally. One of the objections to the reports is that almost all of them concern territory which is essentially free from our major and most serious cause of hay fever—ragweed. The favorable papers deal mainly with parts of Arizona, the Northwest and Europe. Several workers in the Central states area have thus far found this method to yield poor results. In about one third of the cases unpleasant gastrointestinal upsets have occurred when moderate doses of pollen were taken by mouth. Tests on absorption conducted by some members of the Chicago Society of Allergy would indicate that ordinarily only a small and ineffectual fraction of the pollen antigen is absorbed from the gastrointestinal tract.

These facts will eventually come to light in authentic and reliable medical periodicals. Much experimentation will have to be done before such a method can be given approval. There

would be no need for the present communication were it not that attempts are being made at premature commercialization of this form of therapy. Several pharmaceutical houses have placed oral preparations of pollen on the market. Their claims are far from conservative and they fail to point out the dangers of this type of treatment. The enthusiastic and unrestrained tenor of this advertising literature will permeate the consciousness of the general medical profession and before long the general public. The Chicago Society of Allergy feels that it is its duty to sound a note of warning not only because of the probable numerous disappointments but also because of the possible dangers inherent in any new and unproved method of treatment. It is suggested that the average practitioner would be wise to postpone any intended change from hypodermic to oral pollen therapy until the method has been given thorough trial under the experienced eyes of allergists in the large allergy clinics of this country.

THE CHICAGO SOCIETY OF ALLERGY
M. R. LICHTENSTEIN, M.D., Chicago, Secretary.

BLOOD TRANSFUSION

To the Editor:—In the April 2 issue of *THE JOURNAL*, page 1113, in the editorial "A New Source of Blood for Transfusion," appears the statement that "the blood grouping corresponds always to that of the mother's blood."

In this connection I wish to mention an observation made while I was an intern at the Methodist Episcopal Hospital in Brooklyn.

While grouping and crossmatching the blood of 100 parturient women with their respective placental bloods. I found that the placental blood had sharp isoagglutination properties, as the editorial states, but that this grouping did not always correspond to that of the mother's blood.

It was found that the mother bore the relation of "universal donor" for her child, or that, whatever the respective groups, the serum of the placental blood never agglutinated the cells of the mother's blood, while the mother's serum always agglutinated the cells of her own placental blood when the previous grouping with known serum had shown these cells to have agglutinogens to the agglutinins in the mother's group.

This work was not continued beyond the number of 100 when it was found that the same work had been done and published from the Brooklyn Jewish Hospital a few years previously, with identical results, from examinations of 500 cases. This work in Brooklyn Jewish Hospital was done about 1926-1929.

T. D. SLAGLE, M.D., Coamo, P. R.

EPIDEMIC DIARRHEA OF THE NEWBORN

To the Editor:—The discussions of epidemics of diarrhea in the newborn in *THE JOURNAL* have emphasized rooms, equipment and the like whereas procedure is of paramount importance. These epidemics cannot be prevented unless all attendants in a newborn service see the necessity for an asepsis closely analogous to that of an operating room.

How are these infections introduced into each infant and how transferred from infant to infant? Obviously they enter an infant's mouth—or possibly the adjacent nose. They would be expected to come from a common source or from a previous case. A mother's nipple may contaminate one baby but cannot directly cause an epidemic unless she nurses more than one. One is reduced to two probable methods of introduction of contaminating material:

1. Droplets from attendants. This source may be prevented by proper masks, properly worn.

2. Infected bottle nipples. The bottle nipple, from the time it is sterilized until it is finally taken from the baby, should be touched by nothing except the baby's mouth and a sterile gloved hand or forceps.

W. D. LUDLUM, M.D., Brooklyn.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

TRAUMA AND APPENDICITIS

To the Editor:—Can acute or subacute appendicitis be brought on by injury, such as a fall from the stairs? M.D., New York.

ANSWER.—At the present time one cannot say definitely that inflammation of a previously healthy appendix can be brought on by an injury, but there is considerable evidence to indicate that it may be a factor in aggravating a previously existing inflammation. Perforation of an otherwise healthy appendix has been found at operation by Sabawala (quoted by Royster, H. A.: *Appendicitis*, New York, D. Appleton & Co., 1927) immediately following a horse kick. Osler (quoted by Royster) in 1899 stated that trauma played an important part, since symptoms had been observed following a fall or a blow in a number of cases. Ludington (quoted by Royster) favored the opinion that mechanical injury may excite an acute attack of appendicitis. Because of the last two authorities the supreme court of Washington has held appendicitis to have been caused by a blow. In fifty cases of so-called traumatic appendicitis Kelly (quoted by Sloan, H. G., in Lewis, Dean: *Practice of Surgery*, Hagerstown, Md., W. G. Prior Company) found a history suggestive of antedating appendical disease in 80 per cent.

Since 1830, when Goldbeck (quoted by Royster) reported a necropsy on a boy following perforation of a gangrenous appendix with symptoms eight days after a fall from a wagon, trauma has been considered as a possible exciting cause of appendicitis. The recurring pressure of a tool handle has also been given as an etiologic factor. In no instance can one be sure of the previous condition of the appendix preceding an injury or eliminate a possible coincidence.

Mechanical and anatomic changes in the appendix are frequent and predispose to inflammation. These may be due to developmental errors resulting in varying grades of bands, strictures, kinks, adhesions, torsion or traction but may also result from overlooked attacks of inflammation, the development of foreign bodies and from physiologic or mechanical changes in the adjacent structures.

It has been held debatable whether the appendix can be injured directly by a blow from without, except rarely when compressed against bone as other parts of the intestine when it may be injured without visible evidence on the abdominal wall.

Royster (*Appendicitis*, p. 53) believed that increased pressure within the appendix following trauma is the usual mechanism of producing inflammation. Sloan (in Lewis: *Practice of Surgery*, vol. 7, chapter 3, p. 2) stated that the swelling incident to trauma is an important cause but that grossly and microscopically the pathologic condition is not to be differentiated from that arising spontaneously.

NAIL POLISHES AND LACQUERS

To the Editor:—I am interested in the public health and medicolegal aspects of certain cosmetics, in particular the nail polishes or lacquers. I understand that the common base for these nail lacquers is ethyl acetate or some similar product and, in addition, talc and pigments. Have any toxicologic studies (especially patch tests) been reported in the literature? Are these polishes or lacquers essentially or potentially harmful? Please cite references.

MEDICAL STUDENT, New York.

ANSWER.—From consideration of the list of ingredients which are present or likely to be present in various commercial nail lacquers and polishes, it is obvious that the studies of toxicology would be too numerous to mention in these columns. For example, the acetates—ethyl and butyl—are well known in industry for their toxic properties. It may also be pointed out that many of the agents used for the removal of lacquer are readily absorbed through the intact skin. Consideration of the toxicity or the possible toxicity of any of these ingredients in connection with its effect on a certain individual involves a question of the ingredients which are present in any one given product, as well as the possibility of the hypersensitivity of that individual to one of those ingredients.

Nail lacquers are solutions of nitrocellulose in various solvents, with the addition of certain aids to solution and plasticizers to make the film flexible: 1. True solvents: acetone, butyl acetate, amyl acetate, ethyl acetate, absolute denatured

alcohol, normal butyl alcohol or glycol ethers, as cellosolve, cellosolve acetate, butyl and methyl cellosolve. 2. Aids to solution: toluene, xylene, benzene, naphtha. 3. Nitrocellulose of various viscosities, drying in from one-half to forty seconds; pyroxylin. 4. Plasticizers: castor oil, tricresyl phosphate, dibutyl phthalate, butyl stearate, camphor, resin.

The irritating effect of nail lacquer is attributed by Gray to the formation of acetic acid in the solvent. In Prosser White's book on Occupational Dermatoses (London, ed. 4, H. K. Lewis & Co., 1934, p. 200) the following statement is found: "Women paint their nails with collodion, or celluloid dissolved in amyl acetate to give them a polished surface. If kept too long, the acetic acid is prone to be liberated and Gray has noted a distressing injury of the nails, from this acid."

These agents, like all the paraffin oils, produce a scurfy dermatitis, and Leitch says they bring about epilation."

Pardo Castello (Diseases of the Nails, Springfield, Ill., Charles C. Thomas, Publisher, 1936, p. 97) attributes the nail injury to the drying action of the solvents in nail lacquer. Writing of fragilitas unguium, he explains: "The cause of brittleness in these cases is excessive and too frequent manicuring. The constant use of colored enamels and of ethyl acetate or acetone to dissolve them produce the excessive dryness and consequently the nails lose their elasticity. Cuticle removers which consist of solutions of potassium hydrate are also contributing factors."

REPEATED ABORTIONS

To the Editor:—A woman, aged 34, married for twelve years, had a three months spontaneous abortion a year and a half after her marriage. Three years later she had a forceps delivery of a 10 pound (4.5 Kg.) boy, who is still alive and well. Three years ago she was again pregnant and, sixteen days before term, delivered a dead baby girl, weighing 7 pounds (3.2 Kg.). The attending physician reported that the fetus appeared to be normal. Two years ago she again had a three months spontaneous abortion. During May 1937, two weeks before term, she delivered a dead boy weighing 7 pounds (3.2 Kg.). During this last pregnancy she was under a physician's constant care. She was receiving injections (probably estrogen) up to the fifth month. At about the time of delivery, she states that she felt the baby turning in her abdomen and she was sure that something had happened. She went to a specialist, but the baby was already dead. To date she has been unable to receive a satisfactory explanation as to the cause of these stillbirths. She is 5 feet 6 inches (168 cm.) tall, weighs 130 pounds (59 Kg.) and has no subjective complaints. Her family history is negative. She had scarlet fever at 17 and a severe attack of poison ivy about ten years ago, followed by repeated mild attacks since then. She first menstruated at 15, is regular every four weeks, her periods lasting from eight to nine days, she has no pain, and the amount of bleeding is normal. The blood Wassermann reaction is negative, as is her husband's. The vagina is roomy, the perineum is fair, the cervix open for one finger, the uterus is anteverted and of normal size, and the adnexa are not palpable. Could you give me any information as to what could be the possible cause, as she is anxious to have another child but is afraid the same thing will happen again?

M.D., Pennsylvania.

ANSWER.—Whether the patient's abortions and stillbirths are accounted for by uterine pathologic conditions such as a subserous myoma, by "defective germ plasm" of the embryos, or by an endocrine imbalance cannot be determined from the data submitted. Trauma (such as coitus) might have been a factor in causing the abortions but would not have caused stillbirths. Possibly lotions containing lead were used for the treatment of poison ivy pruritus. Lead is recognized as an abortifacient if absorbed in sufficient quantity. Cases such as the one presented are sometimes never understood. More often, study reveals an abnormality which can be corrected with subsequent normal reproduction. Such a study would include: 1. Basal metabolic determinations on the patient before and during pregnancy. If low, the rate should be raised by thyroid administration, remembering that the "normal" basal metabolic rate during pregnancy may be as high as plus 25. Patients with deficient thyroid secretion are prone to miscarry. 2. A provocative Wassermann test, since syphilis is the chief cause of stillbirth. 3. Investigation of the diet, with particular respect to calcium and possibly vitamin E. Even if the diet appears adequate, it would be wise to prescribe additional calcium (as milk or dicalcium phosphate) and vitamin E (as wheat germ oil) during the next pregnancy. 4. Consideration of endocrine therapy. The substances required, and particularly the quantitative studies of the hormone content of the blood and urine which should precede such therapy, are expensive and for that reason may properly be deferred until other possible abnormalities have been investigated and dealt with. Kane (*Am. J. Obst. & Gynec.* 32:110 [July] 1935) reported successful treatment of thirty-six of forty patients with habitual abortion. He prescribed progesterone every other day for ten doses with intervals of three weeks between series of injections. The

endocrine therapy was supplemented by administration of thyroid substance and sodium iodide and was continued until the end of the fourth month. It is obvious that general systemic diseases such as nephritis and diabetes must be ruled out before any specific treatment is undertaken for the relative sterility.

HYPERHIDROSIS

To the Editor:—A man, aged 38, has been troubled for the past year with excessive sweating occurring at least once a day and only after masticating his food. His past history is essentially negative. The blood count, Wassermann reaction and basal metabolic rate are normal. Physical examination is negative. The man exhibits no nervous symptoms. He is anxious for cure, as his occupation is outdoor work and the necessity of leaving a restaurant bathed in sweat leaves him very uncomfortable.

M.D., Connecticut.

ANSWER.—Hyperhidrosis, local or generalized, brought on by eating, has been reported by a number of observers. The odor or taste of foodstuffs, in one case only acid foods (Hall, Robert: Transient Unilateral Hyperhidrosis Immediately Following Eating of Highly Acid Foodstuffs, *Irish J. M. Sc.*, October 1923, p. 291) were provocative. Answers to queries in *THE JOURNAL*, Jan. 11, 1936, page 148, and April 17, 1937, page 1360 and a criticism of the former Feb. 8, 1936, page 487, deal with the subject of hyperhidrosis. The writer of the criticism emphasizes the occurrence of sweating in connection with migraine rarely in the absence of acute symptoms.

J. K. Mayr, writing on the subject in the *Handbuch der Haut und Geschlechtskrankheiten*, Berlin, Julius Springer 13:4, 1932, makes the statement that points can be found at all levels in the central nervous system, from the cerebral cortex to the peripheral endings of the nerves, at which irritation may cause sweating. The sympathetic and parasympathetic systems also affect the sweat apparatus, pilocarpine, the stimulant of the parasympathetic, causing profuse sweating.

Neuroses of various sorts may cause excessive sweating and this in spite of an appearance of great nervous stability. This is the probable cause of the phenomenon in the case cited. A careful examination of the nervous system, including spinal fluid tests and scrutiny of the ocular fundus, is indicated. A psychiatric examination may be necessary. If these fail to show the cause of the trouble, an effort should be made to change the habits of the patient, lessening or abolishing the noonday meal, so that it will not be necessary for him to go outdoors immediately after eating.

NAPHTHALENE CATARACT

To the Editor:—A white man aged 30, a longshoreman, has a fully dilated, fixed, right pupil with rupture of the sphincter, tremulous iris, large gibbous separation of the retina superiorly and a homogeneous hazy vitreous through which the remainder of the fundus can be seen only as a deep red reflex. Vision was reduced to light projection. The left eye was similarly affected except that the pupil was normal and reacted to light. No separation of the retina could be seen, although within a few days a small separation appeared in the inferior temporal quadrant. Since then the vitreous opacities have cleared in both eyes, but the function of the retina has been so badly damaged that vision has been reduced to hand movements at a few feet. The man had been handling naphthalene and was addicted to alcohol. I am going to attempt some experimental work feeding laboratory animals alcohol and naphthalene in an effort to produce similar lesions and would therefore appreciate any information you may give as to the dosage and methods of administration used by previous investigators studying the effects of naphthalene on the eye.

M.D., Boston.

ANSWER.—The production of naphthalene cataract was first observed by Bouchard in 1886. The recent experimental work has been reviewed rather completely by D. R. Adams (*Brit. J. Ophthalm.* 14:49 [Feb.], 545 [Nov.] 1930). The pure crystalline naphthalene is dissolved in 15 cc. of warm liquid petrolatum and is fed to rabbits or white rats by means of an esophageal tube. The daily dose is from 2 to 3 Gm. This is continued until complete production of the opacified lens has been effected. Margherita C. Bourne (*Brit. J. Ophthalm.* 17:210 [April] 1933) has shown that the maintenance diet given to the animal with the naphthalene has a decided influence on the production of cataract. She found that if the diet consisted of oats and cabbage no lens changes occurred, although the vitreous and retina were greatly modified. If bran and carrots or oats were fed to the animal, complete cataracts were an early result. Biondo demonstrated that naphthalene vapors caused only a local and superficial reaction on the eyes and that this is temporary (*Am. J. Ophthalm.* 17:382 [April] 1934). Garcia Miranda felt that the retinal lesions were first noted in six hours. Changes occurred in the vitreous in from six to twelve days and in the lens much later. The cataract was felt to be secondary in nature (*Am. J. Ophthalm.* 17:571 [June] 1934).

AMEBIC DYSENTERY AND AMEBA CARRIERS

To the Editor:—Are the persons who had amebic dysentery in 1933 and 1934 and were apparently cured still proving to be a problem? Is there any available experience on that point? Presumably occasional stool examinations should be made in such cases. If amebas are found without symptoms, is the treatment of choice the same as if clinical symptoms appear?

WILLIAM S. CHASE, M.D., Akron, Ohio.

ANSWER.—Few of the persons who had amebic dysentery in 1933 and 1934 are still proving to be a problem. A few persons did present themselves for treatment during 1937 because of recurrence of their symptoms. These persons evidently were suffering from chronic amebic dysentery, which may follow a severe acute attack. In the chronic form there are recurrent attacks of dysentery with intervals in which there may be actual constipation. In these chronic cases the dysenteric attacks may recur for years.

It is advisable, therefore, that those who have had amebic dysentery should have occasional stool examinations, not only to detect recurrences but also to determine whether they are carriers.

The treatment of carriers is not the same as the treatment of those with clinical symptoms. According to Charles F. Craig (Amebiasis and Amebic Dysentery, Springfield, Ill., and Baltimore, Charles C. Thomas, 1934, p. 292) the most efficient and safest drug for the treatment of carriers is chiniofon. Emetin, bismuth compounds and the iodides as well as the arsenicals should not be used in the treatment of carriers unless other less toxic drugs have failed in eliminating the infection.

TREATMENT OF DOG BITE

To the Editor:—Feb. 1, 1938, a patient came to me with a lacerated wound on the left lower leg, caused by a dog bite. As far as I knew, the only thing to do was to cauterize the wound, which was one inch long and one-half inch deep, with fuming nitric acid, keeping the wound open and covering it with disinfectant dressings. The wound healed in about six weeks, leaving a deep scar. The patient tells me my treatment has been severely criticized by some other doctors, who claimed that I should have washed out the wound and stitched it. According to what I learned, washing a wound caused by a dog bite does not prevent rabies; besides, when a cauterization has been performed, it would be incorrect treatment to close up the wound with stitches. I think my procedure was right, and I should like to have your opinion as to its correctness. Since cauterization, especially in a large lacerated wound, always causes some sloughing and consequently scar tissue formation, it is simply a misfortune that the patient received a deep and long lacerated wound.

M.D., New York.

ANSWER.—The answer to this query depends entirely on the dog. If the dog escaped and was unknown, the treatment given was entirely correct, that is, to use "fuming" nitric acid and cover with a sterile dressing. Certainly when cauterization with nitric acid has been done the wound should not be closed but should be allowed to heal by granulation and scar formation.

If the dog was known, however, and could be impounded for observation against rabies, the situation would be different. If the dog was known to have rabies or strongly suspected of having rabies at the time of the accident, the treatment carried out was correct; but if the dog was not known to have rabies and could be impounded and watched, it would be better to cleanse the wound carefully with soap and water, irrigate abundantly with sterile water after debriding the edges, and close the wound with sutures. If after this procedure the impounded dog developed rabies, of course, the Pasteur treatment should be given.

UREA AS DIURETIC

To the Editor:—The use of urea as a diuretic in the treatment of congestive cardiac failure has been known for a long time. I should like to know the mechanism of this action of urea and its role in normal renal physiology.

M.D., New York.

ANSWER.—The diuretic effect of urea depends on osmotic action in the lumen of the renal tubule. Because of its low molecular weight, urea exerts considerable osmotic pressure in solution, about one-half the pressure of an equimolecular solution of sodium chloride. The reabsorption of water from the glomerular filtrate by the tubular epithelium, chiefly in the loop of Henle and the distal convoluted tubule, results in a concentration of urea which in man may reach 4 or 5 per cent. If the blood urea is artificially elevated, an identical increase occurs in the urea concentration of the glomerular filtrate. Therefore, less water can be reabsorbed before the urea solution in the lumen of the tubule reaches a concentra-

tion capable of neutralizing, osmotically, the limited vital energy of the tubular epithelium. The water that fails of reabsorption increases the urinary output. Practically, the usefulness of urea as a diuretic is limited by several factors, such as the rapid diffusion of urea to nearly all body cells (thereby necessitating the administration of large amounts of urea), the back diffusion of urea from the lumen of the renal tubule into the epithelium (normally averaging 50 per cent of the urea in the glomerular filtrate), the dependence of diuresis on good renal function, and the nauseating effect of the drug on some patients.

VITAMIN C IN BLOOD DYSCRASIAS

To the Editor:—Can you give me information on the use of cevitic acid (ascorbic) acid in hemophilia, purpura and other blood dyscrasias?

ALBERT S. BORSKA, M.D., Altoona, Pa.

ANSWER.—In recent years many reports on the use of vitamin C (cevitamic acid) in hemorrhagic conditions have appeared in the literature and have been reviewed by I. S. Wright (*Am. J. M. Sc.* 192:719 [Nov.] 1936) and by Wilder and Wilbur (*Arch. Int. Med.* 59:512 [March] 1937). In view of the beneficial effect of cevitic acid therapy in the hemorrhagic diathesis of scurvy, this therapy has been tried in other hemorrhagic conditions such as thrombocytopenic purpura, Henoch-Schönlein's purpura and familial hemophilia, with apparently successful results reported by several European authors. Wright and Lilienfeld (*Arch. Int. Med.* 57:241 [Feb.] 1936), however, could not verify the view that cevitic acid, even in large doses administered intravenously, had any effect in these conditions and attributed the good results reported by others to natural remissions which occur in these diseases. Furthermore, scurvy may simulate thrombocytopenic purpura or hemophilia, for occasionally there may be present a low platelet count which responds to vitamin C therapy.

Wilder and Wilbur also concluded that vitamin C therapy in hemorrhagic conditions other than scurvy usually yielded disappointing results. However, in all such conditions if the capillary resistance test shows increased capillary fragility this would lead to the suspicion of vitamin C deficiency and a therapeutic test should be carried out.

DRAINAGE AFTER CHOLEDOCHOTOMY

To the Editor:—Following choledochotomy is the T drain the most satisfactory or are there some who believe that a part of a catheter placed within the lumen is better? In the latter instance it would seem that in order to avoid leakage the tip would have to extend beyond the sphincter of Oddi and a duodenal tube kept in until after the common duct catheter had passed. Would this endanger the pancreas?

HAROLD E. MARKS, M.D., Somerville, Mass.

ANSWER.—A rubber catheter or a T or an L shaped rubber tube may be used satisfactorily as a common duct drain. If the duct opening is well sutured about the drain there should be no leakage.

Ordinarily it is not desirable for the tube to extend through the sphincter of Oddi into the duodenum.

To permit better drainage and to avoid possible blockage of the end of the tube, several openings may be cut at the sides.

The patency of the outlet of the common duct may be tested at operation by the injection of water or by the passage of a small catheter or suitable instrument. Caution should be taken in any dilation of it, as rupture of the duct wall may lead to peritonitis or postoperative swelling and obstruction of the lumen. This may also involve the pancreatic duct, and when it joins the common duct outside the duodenal wall obstruction of the common lumen of the outlet even by a spasm might favor a reflux to the other ducts of either bile or pancreatic juice, depending on the pressure.

Acute pancreatitis has followed cholecystectomy without drainage of the common duct, probably because of a reflux of bile. Acute cholecystitis has followed a reflux of pancreatic juice into the gallbladder.

While it is probable that a tube passed through the sphincter into the duodenum may produce some temporary obstruction of the lumen of one or both ducts, it is not likely that any reflux will develop with external bile drainage and little pancreatic secretion.

Drainage of the common duct should be done when there is any possibility of obstruction, since occasionally instillation of iodized oil into the common duct drain has been shown to extend into the pancreatic ducts.

One may use occasionally two rubber tubes in the common duct, one to drain the bile externally while the other may be

passed through the sphincter for the introduction of fluids or for its effect in dilating the sphincter. Parenteral injection of fluids is now usually preferred.

A rubber tube may be buried in the common duct with one end extending into the duodenum for internal biliary drainage with primary closure of the common duct, especially after end to end suture. The duodenal end should be left long so that peristalsis will carry the tube away as soon as fixation sutures of catgut are absorbed. This procedure should not endanger the pancreas.

INTRAVENOUS OR SUBCUTANEOUS INJECTION IN PREGNANCY TEST

To the Editor:—In the rabbit pregnancy test must the urine be injected intravenously? If it can be injected subcutaneously, what is the dosage of the urine and how long after the administration of the urine are the ovaries examined? Is the test as reliable when the urine is administered (in larger doses) subcutaneously as when the urine is injected intravenously?

M.D., Pennsylvania.

ANSWER.—The Friedman test for pregnancy, with virgin female rabbits, or the Schneider-Priest modification, has for the basis of its technic the intravenous injection of the first morning voided specimen. The ear vein of the rabbit is so easily accessible under most circumstances that the use of other modes of administering urine is not necessary. It is possible to obtain a test by the use of subcutaneous injection of urine but there are so many disadvantages as compared with the intravenous route that the slight extra effort is worth while.

The subcutaneous test requires more time (seventy-two rather than forty-eight hours), more urine (15 cc. daily for two days instead of 10 cc.), and the results are not as reliable as with the intravenous route because of the slower absorption of urine and because of the possibility of producing an inflammatory reaction in the tissues, which might hinder or stop absorption.

The intraperitoneal injection is superior to the subcutaneous because the urine is absorbed much more rapidly through the peritoneum than from the subcutaneous tissues, the absorption is more complete and there is less chance of producing inflammatory reaction or gangrenous sloughing of the tissues. The subcutaneous and intraperitoneal modes of administering urine result in a greater number of false negative results.

BEE VENOM FOR RHEUMATISM

To the Editor:—Is there any medical authority for the use of bee venom in the treatment of rheumatic infections?

EUGENE C. LOWE, M.D., Miami, Fla.

ANSWER.—For generations it has been widely believed that the sting of bees is a cure for rheumatism. The first reference in the literature concerning its use in the treatment of rheumatoid arthritis was published in 1859 by Demartis. Terc wrote at some length concerning its use in this connection in 1880. More recently several bee venom preparations have been placed on the market. They are supposed to contain the natural secretion of the honey bee in physiologic solution of sodium chloride. To date, no one has proved that bee venom is a specific form of therapy in rheumatoid arthritis. Because it is a good counter-irritant, some relief may be obtained following its use. A more enthusiastic report concerning bee venom therapy appears in Beck's book "Bee Venom Therapy," 1935, Appleton-Century Company, New York.

IRON IN CITY WATER SUPPLY

To the Editor:—In what ways would a water supply containing 0.9 part per million of iron be objectionable? Do you consider iron removal necessary if this water is to be used for a city water system? If so, what would be the cheapest method of removal that would be effective?

E. J. SCHWINGHAMER, M.D., Grenora, N. D.

ANSWER.—The United States Treasury Department standard for iron content in water used on interstate carriers suggests a limit of 0.3 part per million. As a rule consumers will object to iron in a public water supply in excess of 0.5 part per million because of the staining of linens, utensils and plumbing fixtures. For these reasons it would be desirable to install an iron removal plant for a city water system having 0.9 part per million of iron in its water supply.

The cheapest and most effective process to use for the removal of iron could be determined only after a complete chemical analysis of the water. It would be prudent for a city contemplating removal of iron from its water supply to employ a competent water chemist and an experienced water-works engineer to advise on the treatment process and the design of the iron removal plant. Processes of iron removal used in water works practice include aeration, sedimentation, coarse contact beds, sand filters and chemical treatment.

HAZARDS OF TANNING

To the Editor:—Please outline the industrial diseases that might be associated with the tanning of leather.

M.D., Pennsylvania.

ANSWER.—The industrial diseases potentially associated with the tanning industry in some measure depend on the type of tanning operation, such as chrome tanning or tannic acid tanning. D. K. Minster (*J. Indust. Hyg.* 7:299 [July] 1925) lists forty-two possible occupational disease exposures in the tanning industry. The agents listed by this investigator as potential sources of occupational diseases are anthrax, sulfureted hydrogen, cyanides, arsenic, mercury bichloride, salt, caustic soda, sulfuric acid, lime, sodium sulfide, arsenic sulfide, bacterial action, parasitic fungi, ammonium sulfide, lactic acid, methan, carbon dioxide, myrobalan, sumac, quebracho, sulfites, sulfuric acid, chrome, hydrochloric acid, formaldehyde, lead, fish, mineral oils, leather dusts, hair, tanbark, aniline, mercury, ammonium acetate, butyl acetate, benzene, naphtha, turpentine, butyl alcohol, methyl alcohol, potassium ferrocyanide, carbon monoxide and metal fumes. In 1931 the Retail Credit Company, an insurance investigating organization, published an extensive report on the hazards connected with tanning. This report furnishes extensive listing of the exposures connected with every common operation in the tanning industry. From a list of some seventy-five individual tannery occupations described in this report and associated with possible exposures, one single item is shown as an example.

Unloader (Hide House): Unloads bundles of hides from box cars standing at the unloading platform. Uses hand trucks; weighs hides and stores them. Chief Hazards: Dampness; rancid odor, due to hides' being salted and in a state of putrefaction; dermatitis; hydrogen-sulfide; arsenic; mercury (rare); salt; anthrax.

ROENTGEN THERAPY IN BRONCHIECTASIS

To the Editor:—What is the present status of high voltage roentgen treatment for bronchiectasis?

M.D., Kansas.

ANSWER.—The use of high voltage roentgen therapy for bronchiectasis has been described by Maurice Berck and William Harris (*THE JOURNAL*, Feb. 13, 1937, p. 517). Berck has previously mentioned the treatment of a single case of bronchiectasis (*J. Mount Sinai-Hosp.* 1:98 [July-Aug.] 1934).

Apparently there are no corroborative reports as yet in the literature. The report analyzes the data from thirty patients with bronchiectasis who were treated and observed over periods of from a few months to two or three years. More than half of this number were benefited by high voltage roentgen therapy with the technic outlined.

The best results apparently were obtained in the group with foul, profuse expectoration. They described aggravations of the symptoms during the first part of the treatment. The inference from the article are that the poorest results are to be expected in the dry types of bronchiectasis. While there is some risk of temporary aggravation of symptoms and other manifestations of roentgen sickness, such risk should not prevent its trial in view of the evident benefits that may be expected.

TWENTY-ONE DOSE RABIES VACCINE— "FUMING" NITRIC ACID

To the Editor:—A child aged 2½ is receiving rabies vaccine, Gilliland I am using the fourteen dose Semple method of treatment. A twenty one dose treatment is recommended by the Gilliland company for leprosy about the face, as my patient has. Are the twenty-one doses better than the fourteen? Is fuming nitric acid to be used as a local cautery? Is there anything else to be done for the prevention of rabies?

J. B. SPRINKS, M.D., Wenaco, W. Va.

ANSWER.—Antirabies vaccine is the only specific preventive available. Presumably the "twenty-one dose treatment" would produce greater immunizing effect. Fuming nitric acid is regarded as the most effective agent for local cauterization of suspected wounds.

VALUE OF TYPHOID VACCINE

To the Editor:—To settle a dispute on the value of typhoid vaccine please give me the consensus of immunologists as to the manner of its action. Do the armies of the world all use typhoid vaccine today? What are the arguments pro and con on this subject? Will you answer specifically the question "Is typhoid vaccine of any value?"

M.D., New York.

ANSWER.—Typhoid vaccination is a good and reliable method of prevention. Antityphoid vaccination is practiced in armies and navies the world over. There are no valid arguments against the proper use of potent typhoid vaccine for preventive purposes.

Medical Examinations and Licensure

COMING EXAMINATIONS STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, May 28, page 1859.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II.* Examinations will be held in all centers where there is a Class A medical school and five or more candidates who wish to write the examination, June 20-22 and Sept. 12-14. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF DERMATOLOGY AND SYPHILOLOGY: *Oral examinations for Group A and B applicants* will be held at San Francisco, June 13-14. Sec., Dr. C. Guy Lane, 416 Marlboro St., Boston.

AMERICAN BOARD OF INTERNAL MEDICINE: *Written examination* will be held at various centers of the United States and Canada, Oct. 17. *Final date for filing applications is Sept. 1.* Chairman, Dr. Walter L. Bierring, 406 Sixth Ave., Suite 1210, Des Moines, Iowa.

AMERICAN BOARD OF OBSTETRICS AND GYNECOLOGY: *General oral, clinical and pathological examinations for all candidates (Groups A and B)* will be conducted in San Francisco, June 13-14. Sec., Dr. Paul Titus, 1015 Highland Bldg., Pittsburgh (6).

AMERICAN BOARD OF OPHTHALMOLOGY: San Francisco, June 13; Washington, D. C., Oct. 8; Oklahoma City, Nov. 15. *All applications should be filed immediately and case reports, in duplicate, must be filed not later than sixty days before the date of examination.* Sec., Dr. John Green, 3720 Washington Blvd., St. Louis, Mo.

AMERICAN BOARD OF ORTHOPAEDIC SURGERY: Chicago, June 10-11. Sec., Dr. Fremont A. Chandler, 6 N. Michigan Ave., Chicago.

AMERICAN BOARD OF OTOLARYNGOLOGY: San Francisco, June 10-11. Sec., Dr. W. P. Wherry, 1500 Medical Arts Bldg., Omaha.

AMERICAN BOARD OF PATHOLOGY: San Francisco, June 13-14. Sec., Dr. F. W. Hartman, Henry Ford Hospital, Detroit.

AMERICAN BOARD OF PEDIATRICS: Detroit, October 26; Rochester, N. Y., November 13; and Oklahoma City, November 15. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

AMERICAN BOARD OF PSYCHIATRY AND NEUROLOGY: San Francisco, June 11. Sec., Dr. Walter Freeman, 1028 Connecticut Ave., N. W., Washington, D. C.

AMERICAN BOARD OF RADIOLOGY: San Francisco, June 10-12. Sec., Dr. Byrl R. Kirklín, 102-110 Second Ave. S.W., Rochester, Minn.

AMERICAN BOARD OF UROLOGY: San Francisco, June 11-13. Sec., Dr. Gilbert J. Thomas, 1009 Nicolet Ave., Minneapolis.

Illinois January Examinations

Mr. Homer J. Byrd, superintendent of registration, Illinois Department of Registration and Education, reports the written examination (graduates of foreign schools given also a practical test) held at Chicago, Jan. 25-27, 1938. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Fifty-four candidates were examined, 50 of whom passed and four failed. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Colorado School of Medicine.....	(1936)	82	
Yale University School of Medicine.....		82*	
Chicago Medical School.....		83, 83	
Northwestern University.....		83,	
(1936) 81,* (1937) 80,* 83,* 84, 85, 85, 86, 86, 86			
Rush Medical College.....	(1936) 84, (1937) 84, 84,*	86*	
School of Med. of the Division of Biological Sciences (1936)		84,	
- 85, 86,* 87*			
University of Illinois College of Medicine.....	(1936)	83,	
(1937) 77, 80, 82,* 83, 83,* 84, 84, 84, 84,* 84,*

Harvard University Medical School.....	(1932), (1933)*	N.B.M.E.x.

* License has not been issued.
† Average grade not reported.

Minnesota January Report

Dr. Julian F. Du Bois, secretary, Minnesota State Board of Medical Examiners, reports the oral, written and practical examination held at Minneapolis, Jan. 18-20, 1938. The examination covered 12 subjects and included 60 written questions. An average of 75 per cent was required to pass. Fifty-four candidates were examined, all of whom passed. Three physicians were licensed by reciprocity and five physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Stanford Univ. School of Medicine.....	(1936) 83.4, 86.6, (1937)		86.6
Georgetown University School of Medicine.....	(1933)		84
Northwestern University Medical School.....	(1937)		87.6
Rush Medical College.....	(1937)		84.4
School of Med. of the Division of Biological Sciences (1937)			86.5
University of Louisville School of Medicine.....	(1933)		89.3

Book Notices

Cutaneous Cancer and Precancer: A Practical Monograph. By George M. MacKee, M.D., Professor of Clinical Dermatology and Syphilology, New York Post-Graduate Medical School and Hospital, Columbia University, and Anthony C. Cipollaro, M.D., Associate in Dermatology, Skin and Cancer Unit, New York Post-Graduate Medical School and Hospital, Columbia University. With a foreword by Francis Carter Wood, M.D. Cloth. Price, \$3.75. Pp. 222, with 245 illustrations. New York: American Journal of Cancer, 1937.

As indicated in the preface, the monograph was prepared for the purpose of aiding in the reduction of the mortality from accessible cancer. Every variety of cancerous and precancerous lesion encountered on the skin and its neighboring mucous membranes is presented concisely and clearly from the standpoint of symptomatology, diagnosis, etiology, pathology and treatment and, best of all, is beautifully illustrated with excellent reproductions of photographs and photomicrographs. A good grade of paper has been used and of course is one factor responsible for the excellent reproductions. The four chapters are on the morbidity and mortality of cutaneous cancer, the precancerous dermatoses, carcinoma and sarcoma, and established therapeutic methods. Extremely precise presentation of the subject matter has made it possible to incorporate almost everything known about this subject, together with the illustrations, in this compact and relatively small volume. For the investigative student a carefully selected bibliography, which incorporates most of the pertinent literature, has been given.

Like syphilis, cutaneous cancer and precancer are commonly treated by physicians in all branches of medicine. For that reason this authoritative volume should be in the hands of every one, general practitioner, dermatologist and physician in other branches of medicine alike, who attempts the treatment of cutaneous cancer or precancer in any of the numerous manifestations. The importance of this statement is evident from recent tabulations, which indicate that about 7 per cent of all deaths from cancer are due to cancer of the accessible parts. There is no question about the fact that early proper diagnosis and treatment by those who attempt the management of such lesions will substantially decrease this high mortality.

Many will not agree with the use of the term precancerous dermatoses to cover many relatively benign conditions, but the authors have considered this fact. Tables such as the ones on pages 145 and 146, indicating the results of different methods of treatment by different physicians, are of little or no prognostic significance, in that they contain no statement with regard to the microscopic grading of the epitheliomas studied and treated. Unfortunately, throughout the book no attention has been given to grading of the squamous cell tumors. It is not sufficient to say that a given lesion is a squamous cell epithelioma. Broders has carefully classified these tumors according to the degree of malignancy into grades 1, 2, 3 and 4, a practical classification which probably should be adopted by every one and which many have already adopted. If one finds histologically that one is dealing with a grade 1 lesion there is relatively little cause for concern compared to the respect one must have for a grade 4 or even a grade 3 specimen. Perpetuation of error is evident in the text on page 32 under *seborrhoeic keratosis*, where that disorder has been confused with senile keratosis, as it was previously confused by Gans and later by McCarthy. Hamilton Montgomery and others have shown that bowenoid changes do not occur in *seborrhoeic keratosis*. Although the authors speak of the possibility of epithelioma developing from sebaceous adenomas and other sebaceous lesions, no mention was noted of true sebaceous cell carcinoma. The reviewer probably noted the omission of this rare condition because he recently saw a sebaceous cell carcinoma of the pubic region in a woman aged 50, the lesion having been first noticed three years ago but having been rapidly enlarging in the past few months. The legends of a number of the photomicrographs constitute the weakest part of the book, and really the only weak part. Some legends are incorrect and others are questionable. As examples, figure 28, labeled *senile keratosis*, is already a grade 2 or grade 3 squamous cell epithelioma. Figure 36, labeled *seborrhoeic keratosis* and early basal cell epithelioma, is a senile keratosis with liquefaction necrosis of the basal cell layer. Figure 41, labeled *carcinoma in kraurosis vulvae*, might better be labeled

grade 4 squamous cell epithelioma. Figure 49, labeled highly malignant epithelioma developing in *leukoplakia*, appears at most to be a grade 1 squamous cell epithelioma if not merely a pseudo-epitheliomatous hyperplasia. Figure 66, labeled *verrucous nevus*, appears to be a typical *verruca senilis* (*seborrhoeic keratosis*). Figures 137 and 139, labeled basal cell epitheliomas, appear to be examples of basosquamous cell epitheliomas, some of the tumor cells being pale staining, an error once made in a publication by the reviewer. Figures 144 and 145, labeled intra-epidermic basal cell epithelioma, are squamous cell epitheliomas in situ presenting features of Bowen's disease. Figure 147, labeled basal cell epithelioma in deep cutis apparently coming from an overlying prickle cell epithelioma, is a classic grade 4 squamous cell epithelioma in the deep cutis imitating a basal cell epithelioma. Figure 153, labeled intradermic mixed cell epithelioma, is a squamous cell epithelioma in situ with individual cell keratinization, a common picture in true precancerous dermatoses. In figure 200, Bowen's precancerous dermatosis, most of the component cells are prickle cells rather than basal cells.

Because of its excellence, and the fact that it is the only complete book on the subject in the English language, as stated, this volume should be in the hands of all students and practitioners interested in the subject, and it is most highly recommended.

Story of a Great Hospital: The Royal Infirmary of Edinburgh 1729-1929. By A. Logan Turner, M.D., LL.D., Hon. F.R.C.P., Consulting Surgeon, Ear, Nose and Throat Department, The Royal Infirmary. Cloth. Price, 10s. Pp. 406, with 38 illustrations. Edinburgh: Oliver and Boyd, 1937.

The Royal Infirmary of Edinburgh, the first of the large voluntary hospitals of Scotland, was founded in 1729. Turner has lovingly depicted the progressive changes which have occurred in this venerable institution, jointly devoted to the alleviation of human suffering and the training of succeeding generations of medical men and women. In his comprehensive story Turner has wisely omitted the years 1929-1937 because, as he justly remarks, many of the present day problems affecting the policy of the institution remain unsolved. From its inception the Royal Infirmary has been a teaching hospital, an essential part of the Edinburgh School of Medicine.

The influence exerted on the founders of the Royal Infirmary by the University of Leiden, the imprint of Herman Boerhaave, who dominated European medicine in the early part of the eighteenth century, are delightfully recounted in chapter III. The teaching of Hippocrates—the return to the study of nature—the belief that accurate observation and experience at the bedside were the basic principles of all medical practice, so inspiringly taught by Boerhaave, were carried back to Edinburgh by such men as John Monro primus, Archibald Pitcairne, Alexander Monro primus, son of John, John Rutherford, Andrew St. Clair, Andrew Plummer and John Innes.

Chapter V succinctly describes the many early unsuccessful and finally successful attempts to awaken public interest in the proposed infirmary. John Monro was the leading spirit in this enterprise. Aug. 6, 1729, the infirmary opened its doors. It boasted of but six beds but was destined to become the largest voluntary hospital in the United Kingdom. Turner pathetically recounts the first inventory taken, when, in addition to the furniture, the commissary possessed "4½ lb. of small candles, 1 lb. of great candles, containing seven, about two carts of coal, 6 pecks of meal and two pecks in bread, 4½ of groats, a peck and a half of sowing seeds and 24 chappin bottles of ale (a chappin is approximately one quart)." The three Alexander Monros, primus, secundus and tertius, were repeatedly ordinary managers and actively engaged in the business of the infirmary board. Chapter VI contains the story of the construction of the Royal Infirmary on land formerly the property of the Dominican Order of Black Friars. It is of academic interest only. Succeeding chapters deal with the system of admission of patients, changes in executive methods and the fierce controversy which ended with the abolishment of the system of attendance by rotation. This decision caused several of the leading surgeons and practitioners to resign and accept chairs elsewhere. A prerequisite to appointment on the attending staff of the Royal Infirmary might well be copied by some of our own hospital.

in the United States. Feb. 3, 1794, the board voted that "no future member of the College of Surgeons shall be admitted to practice as an Attendant Surgeon in the Infirmary till after the lapse of five years from the time of his being admitted a member of the Incorporation of Surgeons."

As early as 1749, John Moultrie of Charleston, S. C., graduated in Edinburgh, to be followed by Benjamin Rush and Adam Kuhn, Casper Wister, Philip Syng Physic, Samuel Bard and others of lesser fame. In the eighteenth century Edinburgh had supplanted Leiden as the medical Mecca. Students came from every country in Europe as well as from both the Americas. In 1847 James Young Simpson experimented on himself with the vapor of chloroform and, satisfied with its possibilities, administered the first chloroform anesthesia in the Royal Infirmary. The patient awoke "with a clear merry eye and placid expression of countenance, wholly unlike what is found to obtain after ordinary etherization!" Typical of the research work which Turner undertook while writing his history is reference to nurse Janet Porter, who served the Royal Infirmary for forty-seven years during which time she was staff nurse to both Syme and Lister.

Much is she worth, and even more is made of her;
Patients and students hold her very dear,
The doctors love her, tease her, use her skill;
They say "The Chief" himself is half afraid of her.

So wrote a patient of Lister's while in the infirmary.

The last decade in the old Royal Infirmary, 1870-1879, marked the election of Lister to the chair of clinical surgery, a position which he held until 1877, when he became clinical professor of surgery at King's College, London. Women medical students were admitted in 1886 but instructed in a separate School of Medicine for Women. Chapters xv to xvii deal with the expansion of the infirmary and progress in teaching methods. Soon after the outbreak of the World War the medical and surgical staffs became sorely depleted, those holding commissions in the naval reserve and territorial army leaving for national service elsewhere, while a large number holding commissions in the Royal Army Medical Corps formed the staff of the Second Scottish General Hospital. The duties of interns were undertaken by senior medical students. The final chapters deal with the remarkable postwar expansion of the infirmary and medical school. The visit of King George and Queen Mary in the summer of 1920 and the writing of their names in the center of the dining room table in the residency—already filled with the names of past and present house physicians and surgeons—was, quite naturally, a banner day for Edinburgh.

With pardonable Scottish pride Turner reminds us that "in the founding of University College, the germ of the University of London, the strongest, single intellectual influence was that of Edinburgh, and, from the example of the Scottish universities, London drew many of its most distinctive features." As medical men we must venerate an institution which gave to the world such figures as the four Monros, James Syme, John Rutherford, William Cullen, John Bell, James Y. Simpson and Lister.

The story of the Royal Infirmary of Edinburgh is charmingly and entertainingly spun by Turner, and he deserves the congratulations of his colleagues for the successful labor of love which he has completed. The volume can be heartily recommended to any student of medical history.

Las miocarditis. Por el Doctor Gregorio N. Martinez, professor titular de la Facultad de medicina de Córdoba. En colaboración con los doctores S. González Astudillo y D. Deza Cenget. Paper. Pp. 191, with 69 illustrations. Buenos Aires. El Ateneo, Librería científica y literaria, 1937.

In discussing myocarditis, Martinez follows the traditional lines of etiology, pathology, symptomatology, diagnosis, prognosis and treatment. There is a helpful introduction describing the author's conception of myocarditis and also a useful classification with groupings made from clinical and anatomic points of view as well as from the standpoint of etiology or of localization; i. e., focal or diffuse types. While clinicians and pathologists may not always be able to fit cases closely into these categories, some such plan is of advantage for purposes of description and easy understanding of the subject. While there

is much condensation there is little slighting of important facts. There are good photomicrographs and electrocardiograms. The clinical features of myocarditis seen in the infections are, as they should be, well stressed and described with considerable detail. The style is clear. One can agree with Professor Castex, who writes a preface, that this book, the result of twenty-five years of observation and study, dealing with an important phase of medicine, is one that can be read with profit by practitioners and undergraduates.

Manual of Clinical and Laboratory Technic. By Hiram B. Weiss, A.B., M.D., F.A.C.P., Associate Professor of Medicine, College of Medicine, University of Cincinnati, Cincinnati, Ohio, and Raphael Isaacs, A.M., M.D., F.A.C.P., Associate Professor of Medicine, Assistant Director of the Thomas Henry Simpson Memorial Institute for Medical Research, University of Michigan, Ann Arbor. Fifth edition. Cloth. Price, \$1.50. Pp. 141. Philadelphia & London: W. B. Saunders Company, 1937.

Many useful laboratory procedures have been developed and standardized since the preceding edition of this useful epitome on clinical and laboratory technic was published. A good portion is included in the present edition. Under the discussion of vitamin C content of the urine it would have been desirable to include the normal values for the urinary excretion of cevitamic acid. The vitamin C saturation test also is not mentioned. The present edition includes additional tests for albumin in the urine, tests for Bence Jones protein, technic of the Addis count, newer hematologic methods (including Isaacs' technic of bone marrow biopsy), Neufeld's reaction, liver function tests, the Takata-Ara reaction, new renal function tests and diagnostic agglutination reactions. These additions have materially increased the value of the manual. Interns and physicians will find this manual useful as a ready reference on gross details of the commonly employed laboratory tests. It is not intended and will not serve as a substitute for a standard textbook on laboratory procedures.

Medical Magic. By David Dietz. Cloth. Price, \$3.50. Pp. 380, with 45 illustrations. New York: Dodd, Mead & Company, 1938.

Among the interpreters of medical science for the public, David Dietz is widely known. His column appears in most of the Scripps-Howard newspapers. He has for some fifteen years attended most of the important American medical meetings and he has visited important medical institutions both in the United States and abroad. He has thus been able to find the drama in medical science without having to create it out of his imagination. He tells his story in a straightforward manner and he has been able by his training in journalism to lend movement and action to objective descriptions. The book is abreast of the times, with excellent sections dealing with the glands, with the newer investigations in neurology, and with work on heart disease and on contagion. The book is furthermore supplemented with a chapter of anticipation as to what the future may bring and with a competent bibliography. The volume may be especially recommended to the youngster in high school who contemplates medicine as a career and who needs the inspiration that a book like this can bring.

Il cancro della mammella: Studio anatomo-patologico e clinico. Dal Dott. Giampaolo Coggi. Clinica chirurgica generale e terapia chirurgica della R. Università di Milano. Diretta da M. Donati. Paper. Price, 35 lire. Pp. 192, with 42 illustrations. Bologna: L. Cappelli, 1937.

This small volume covers with considerable completeness the pathogenesis of cancer of the breast, discusses precancerous lesions, has an excellent chapter on the pathologic anatomy with clear photomicrographic illustrations, and surveys classification, bilateral carcinoma, carcinoma of the male mamma, symptomatology and treatment. An extensive bibliography not at all limited to Italian writers is appended. The recent experimental work on the effects of the administration of endocrine substances in the causation of tumors in animals is surveyed. Attention is called to the fact that it was Wintz in 1920 who introduced the idea of roentgen sterilization as a part of the radiologic and surgical treatment of cancer of the breast, and the proposal of Steel that such sterilization be undertaken to prevent the possibility of pregnancy is commended. There are good chapters on grouping, cell secretion and the morphology and extent of the tumor in connection with prognosis. The proper technic for mastectomy, which follows the classic lines,

is excellently illustrated. Finally, preoperative and postoperative radiotherapy are considered. The author is conservative in his attitude on this subject. Altogether the monograph is an excellent one.

Die Geschlechtskrankheiten und ihre Gefahren für das Volk. Von Dr. med. Johannes Breger, Oberregierungsrat i. R. Second edition. Paper. Pp. 150, with 108 illustrations. Berlin: R. v. Decker's Verlag, G. Schenck, 1937.

This book reviews the history of the venereal diseases and their relationship to prostitution. The dangers of the disease to youth and to the whole population are vividly portrayed, but the curability of syphilis and the importance of its adequate treatment are emphasized. The possible late results of gonorrhea, including the large percentage of sterility caused by it, are discussed and attention called to the necessity of tracing sources of infection in venereal disease control. The enormous economic loss caused by these diseases is shown. Statistics are presented from various countries showing that the incidence of these diseases is apparently being decreased by the fight which has been waged in recent years against them. The monograph is profusely illustrated by cuts from both German and foreign sources, including a number from English and American periodicals. It is an interesting and informative popular review of the subject.

The Human Mind. By Karl A. Menninger. Second edition. Cloth. Price, \$5. Pp. 504, with 16 illustrations. New York: Alfred A. Knopf, 1937.

Since its first edition in 1930, more than 160,000 copies of this book have been sold in the United States. It is now revised completely and printed in a handsome new edition, corrected, enlarged and rewritten. Particularly has the section on psychoanalysis been rewritten, because in the interval Dr. Menninger has gone a considerable distance in his relationship to that branch of psychiatry. He considers psychoanalysis the only real mental hygiene of which he has knowledge. There will be many differences of opinion as to whether or not the new book is as safe for the average reader as was the first edition. Of this book certainly it may be said that it is easily readable and that the numerous case reports have been selected in a manner to hold the reader's interest—almost like fiction. The new emphasis on the psychoanalytic point of view has certainly not diminished its interest. The book is supplemented by a selected bibliography and by an adequate index.

Handbook on Nasal Accessory Sinuses. By Frank L. Alloway, B.Sc., M.D., Otolaryngologist at Holston Valley Com. Hospital, Kingsport, Tennessee. Cloth. Price, \$2. Pp. 121, with illustrations. Kingsport: The Author, 1937.

Alloway's booklet is too sketchy for the laryngologist but may be of some use to the general practitioner who has forgotten what he learned about sinuses in medical school. By reason of its brevity and elimination of all but the most salient essentials, it may have a field of usefulness for the man who is too busy to look up his subject in a textbook.

Eleventh Annual Report of the Memorial Ophthalmic Laboratory, Giza, Cairo, 1936. Ministry of Public Health. Paper. Price, P. T. 25. Pp. 147, with illustrations. Cairo: Schindler's Press, 1937.

This is a report of the work and activities of the Giza laboratory in Cairo, founded primarily for research in trachoma. The administrative phase of the report is short. The professional report comprises eighty-seven pages, in which may be found a statistical list of pathologic specimens and of interesting cases that were referred to the laboratory for consultation. Many of the latter are described in detail and well illustrated with black and white as well as colored pictures. The most interesting part of the entire report is that devoted to the research work, mainly on the etiology of trachoma, the epidemiology of the acute ophthalmias encountered in Egypt (and there are plenty) and observations on the pathogenesis of spring catarrh. There is so much meat to this section that it does not lend itself well to abstract. The administrative work of an institution that accomplished as much as does the Giza laboratory must be a chore and it seems rather a pity that such time-robbing work should devolve on the shoulders of such a research man as the director, Dr. R. P. Wilson. Ophthalmology suffers from these incursions on his time.

Rose & Carless Manual of Surgery. Edited by William T. Carless, B.S., M.D., F.A.C.S., Professor of Surgery and Director of the Department of Surgery, St. Louis University School of Medicine. American (Fifteenth) edition from the Fifteenth English edition by Cecil P. G. Wakeley, D.Sc., F.R.C.S., F.R.S., Senior Surgeon, King's College Hospital, and John B. Hunter, M.C., M.Chir., F.R.C.S., Surgeon, King's College Hospital, London. Cloth. Price, \$9. Pp. 1536, with 929 illustrations. Baltimore: William Wood & Company, 1937.

This edition of the Rose and Carless Manual of Surgery edited by Coughlin, continues to serve the purpose of a standard textbook on general surgery. It is not only particularly suitable for undergraduate teaching purposes but serves as a reference book for the general practitioner as well. The purpose of the book is not to describe surgical procedure in detail or to present results, but instead to give a rather broad view of the field of general surgery. The book is well written and very understandable.

Gegenwartsprobleme der Augenheilkunde. Herausgegeben von E. Thiel. Unter Mitarbeit von Albrecht, et al. Sammlung der Vorträge vom VIII. Fortbildungskurs für Augenärzte in Frankfurt am Main, 21.-25. Februar 1937. Boards. Price, 16 marks. Pp. 280, with 166 illustrations. Leipzig: Georg Thieme, 1937.

This is a collection of addresses that were given in the eight instruction course for ophthalmologists, held in Frankfurt Feb. 21-27, 1937. As each address is an entity, a review of the subject matter is out of the question. There were twenty-seven lectures, of which a comparatively small number were by ophthalmologists, although the audience was comprised entirely of ophthalmologists. General medical men, neurologists, brain surgeons, psychologists, illuminating engineers and the like talked on the borderline topics of ophthalmology, each in accordance with his own estimation of the mental capacity of the audience. As a result, the caliber of the papers varies enormously. This is at variance with the present day regimentation of the country. The bookmaking is excellent, as are the illustrations, some of which are colored.

L'acétylcholine et l'adrénaline: Leur rôle dans la transmission de l'influx nerveux. Par le Dr. Z. M. Bacq, agrégé de l'Université de Liège. Bibliothèque scientifique belge, Section biologique. Paper. Price, 25 francs. Pp. 114, with 15 illustrations. Paris: Masson & Co, 1937.

This booklet aims to give a modest contribution to the history of epinephrine and acetylcholine in biology, and especially the adrenergic and cholinergic theory of nerve impulses. This is known also as the theory of humoral transmission. Encumbering details are suppressed. Most of the work on these drugs that applies to this theory has been done in the last thirty years. Many of the pioneers are still actively working. The author has worked with many of them and is himself a contributor. He is therefore eminently fitted, by knowledge of the subject, for the task. The story is told clearly, and in French that English readers can easily understand. The history and progress of work in the subject are portrayed in romantic style and given in 100 pages. The evidence for and against the adrenergic and cholinergic theories is given so interestingly that the general reader will welcome it. Those who wish to go deeper will find a list of references to the literature of about twenty-five authors, whose work has revolutionized the theory of nerve impulses.

Methods of Treatment. By Logan Clendenen, M.D., Clinical Professor of Medicine, Medical Department of the University of Kansas. Sixth edition. Cloth. Price, \$10. Pp. 879, with 103 illustrations. St. Louis: C. V. Mosby Company, 1937.

Many of the sections of this edition have been rewritten to include recent advances in therapeutics and materia medica and to bring the text into accord with the eleventh edition of the Pharmacopeia. The book differs from most other textbooks of therapeutics through the inclusion of rather extensive discussions of dietetics, medical gymnastics and massage, hydrotherapy, climate therapy, aerotherapy and heliotherapy. It even contains extensive reference to the better known American spas as well as to certain English, French, German and Austrian spas. There is a large section dealing with psychotherapy. The portion of the book dealing with materia medica discusses drugs under the heading of the various systems of the body and under subheadings according to their action on that system. Similarly, the latter portion of the book deals with various diseases, which are grouped according to the principal system

that is affected. In the preface the author forestalls criticism of minor details. Therefore the following suggestions are not intended to be critical but rather helpful in the formulation of subsequent editions. Epinephrine and ethylene are described as "not official" and while some items which are included in N. N. R. are so indicated, the N. N. R. designation is omitted in mercury oxycyanide, silver arsphenamine and trichlorethylene. The author believes that this is the only book in which therapeutics is so extensively discussed along with materia medica and pharmacology. He pleads that the book represents the judgment and opinion of the author and is not necessarily comparable with the latest therapeutic advances or the most recent consensus. The volume should prove useful to the general practitioner, particularly because of the amount of space devoted to subjects that are not usually included in books on this subject. It should serve as a useful addition to any physician's therapeutic library.

Miscellany

PREVENTION OF DANGEROUS TICK BITES

The principal danger of the tick that carries Rocky Mountain spotted fever in the East lies in its bite. The East has an unusually large number of common dog, or wood, ticks this year, some being reported for the first time from vacant city lots. Even though only one in several hundred of these ticks may carry the fever virus, that one tick, which cannot be distinguished from the rest, may cause a fatal infection. No cure for Rocky Mountain spotted fever is known. Its mortality rate is one out of every five persons infected.

After passing the first part of its life as a small parasite on field mice, the tick waits in tall grass and underbrush for larger host animals. Cutting all grass and underbrush around houses and pathways, therefore, is one way to protect dogs and people from tick bites.

Bites can be avoided by a few simple precautions, according to Dr. F. C. Bishopp of the Bureau of Entomology and Plant Quarantine, U. S. Department of Agriculture. Keeping ticks from gorging themselves on the blood of dogs is a protective measure. A pair of forceps is all that is needed in removing ticks from dogs to which only a few have attached themselves. Dusting every five days with derris powder is necessary for dogs supporting a large number of ticks. Ticks should be handled with great care. Infection can be contracted by crushing a tick full of blood from an animal that has had the fever.

Boots laced up over trouser legs protect men walking through tick-infested areas. Ticks are usually picked up from grass or weeds close to the ground.

Ticks always work their way upward before attaching themselves to their human host. The back of the neck and head are their favorite feeding places. Careful examination of heads, especially children's, at least twice a day, will reveal the presence of a tick in time to prevent a fatal bite. Examination of the whole body is necessary after exposure to ticks. An effective way to detick clothes is to place them in a vessel that can be tightly covered, and set on top of them a pan containing half a teacupful of carbon tetrachloride or carbon disulfide. A few hours of such fumigation kills the ticks.

Don't wait for the doctor to remove a tick. The important thing is to get the tick off as soon as possible. Any one can disinfect the bite and the surrounding tissues by inserting into the exact spot where the tick was attached a round toothpick that has been dipped in iodine and drilling it in slightly.

The American dog tick is widely distributed throughout the United States east of the Rocky Mountains, as well as in western and northern California and in parts of Oregon. It is most numerous along the eastern coast from Massachusetts to Florida, especially within a few miles of the shore. Both Texas and Florida have a great many ticks—also some inland areas, such as southern Iowa and parts of Wisconsin and Minnesota. Islands off the coast of Massachusetts and of South Carolina are heavily infested with ticks, especially Martha's Vineyard, Nantucket and Naushon. Tick numbers fall off along the sea coast from Marion, Mass., westward. The Narragansett Bay islands are

heavily infested. A few ticks have been reported on the west side of that bay and as far west as Stonington, Conn. There are large numbers of ticks on Long Island, especially the eastern half, and along Chesapeake Bay in Maryland. They are rarely seen west of Blue Ridge.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Evidence: Admissibility of Hospital Records.—The defendant was charged with performing a criminal abortion. At the trial, over the defendant's objection, the entire hospital record of the complaining witness was admitted in evidence after the record clerk of the hospital had testified that it was a fixed rule of the hospital to keep an individual record for each patient. The record clerk disclaimed any knowledge of the contents of the record but stated that it was prepared by an intern no longer connected with the hospital and whose whereabouts she did not know. The trial court entered a judgment of guilty and the defendant appealed to the Supreme Court of Rhode Island.

In Rhode Island, said the court, a hospital record is admissible in evidence, if properly authenticated, as an exception to the hearsay evidence rule. It is admissible, however, only to the extent that it relates to the diagnosis, treatment and medical history of the case. Before the record is admitted, it must affirmatively appear that such records are regularly kept in the course of the hospital's business, and the person whose duty it was to keep that record, if living, competent and within the jurisdiction of the court, must testify that the entry was made in the regular course of business in his handwriting or under his immediate supervision. If the person who made the entries is dead, incompetent or beyond the process of the court at the time of the trial, other witnesses may identify the record as to how and by whom it was kept. In the present case, the court continued, the evidence failed to show any excuse for the absence as a witness of the intern who made the record. It was shown only that the record clerk did not know where the intern was located and that he was no longer connected with the hospital. The record, therefore, was not properly identified and was for that reason not admissible in evidence.

Furthermore, the court said, a statement in the record that the complaining witness had, on the day before she was admitted to the hospital, gone to a "female abortionist" was clearly a narration of a past event beyond the personal knowledge of the writer of the statement. Too, it tended to establish the commission of the crime for which the defendant was on trial and of which she was presumed to be innocent until proved guilty by competent evidence beyond a reasonable doubt.

The judgment of conviction was accordingly reversed and the cause remanded to the trial court for a new trial.—*State v. Guarneri (R. I.), 194 A. 589.*

Dental Practice Acts: Restrictions on Advertising Not Indefinite.—The Illinois dental practice act prohibits the advertising of free dental service as an inducement to secure patronage, the advertising of prices or fees for services, the use of "cappers" or "steerers" to obtain patronage, the use of specimens of dental work or posters or any other mediums calling the attention of the public to any person engaged in dentistry, and the giving of public demonstrations of methods of practice in any place other than in a regular dental office. The defendant, a licensed dentist, was convicted of violating the act and appealed to the Supreme Court of Illinois.

The act, said the court, does not violate the rule of law that the provisions of an act must be definite and certain. The act forbids certain types of advertising. It then sets out what advertising is permitted. It leaves no doubt about the rights of dentists to advertise, and they may do so only within the limits it sets. The words "cappers" and "steerers" have a

commonly accepted meaning, and the legislature was not bound to define them. When the defendant employed solicitors, a loud speaker, a card trick, a lecture, a sale of tooth powder, with a right to the purchaser to have his teeth cleaned free, and when his agents performed so-called free and painless extractions in an open storeroom into which barkers urged persons passing along the sidewalk, he knew, or should have known, without guessing, that he was violating the plain provisions of the act.

The defendant, in the opinion of the court, was in no position to complain that a provision of the act authorizing a dentist to notify the public that his prices have been reduced on account of a period of economic stress or depression was void for uncertainty, for he was not charged with so advertising when there was no economic stress and depression. Even if this provision were void, it could readily be deleted without invalidating the whole act.

The conviction was accordingly affirmed.—*People v. Dubin (Ill.)*, 10 N. E. (2d) 809.

Cannabis: Sufficiency of Information Charging Sale of Cannabis.—The defendant was convicted under an information charging him with selling "eight cigarettes containing cannabis, from which the resin had not been extracted." He appealed to the Supreme Court of Florida, where an equal division of the court resulted in an affirmation of the conviction.

The uniform narcotic drug act of Florida makes it unlawful for any person to sell cannabis, defined to include "(a) the dried flowering or fruiting tops of the pistillate plant *Cannabis Sativa* L., from which the resin has not been extracted, (b) the resin extracted from such tops, and (c) every compound, manufacture, salt, derivative, mixture, or preparation of such resin, or of such tops from which the resin has not been extracted." Three justices, who thought the conviction should be reversed, pointed out that the information charged only that the defendant sold cigarettes containing "cannabis from which the resin had not been extracted" and that the information was therefore too vague. Said these justices:

The plaintiff in error was charged with selling cigarettes containing cannabis from which the resin had not been extracted, but cannabis is the name of a plant which is dioecious in nature, the dried leaves and flowering tops of the female plant only contain the resin or the properties from which the narcotic drug is produced. . . .

We are of the opinion therefore that the information was insufficient to clearly apprise accused of the nature and cause of the accusation against him because of the sale of cigarettes containing cannabis from which the resin had not been abstracted may relate to the resin of the staminate plant, the resin of which appears to be harmless.

The remaining three justices of the court were of the opinion that the information was sufficient to charge a violation of the act.—*Simpson v. State (Fla.)*, 176 So. 515.

Medical Practice Acts: Validity of Information Stating Charges Disjunctively.—The defendant was convicted of violating the medical practice act of Illinois and sentenced to imprisonment in the county jail for one year and to pay a fine of \$100. After the intermediate appellate court had affirmed the conviction (7 N. E. [2d] 160), the defendant appealed to the Supreme Court of Illinois.

The first count in the information on which the defendant was convicted charged that on a certain date he did "diagnosicate or attempt to diagnosicate, operate upon, profess to heal, prescribe for or otherwise treat an ailment or supposed ailment of another, to wit: did then and there prescribe the taking of certain tablets internally. . . ." The second count charged that he did "unlawfully suggest, recommend, operate upon, profess to heal or otherwise treat an ailment or supposed ailment of another . . . namely: did unlawfully prescribe . . . the taking internally of certain tablets of unknown composition. . . ." The third count charged that he did "unlawfully attach the title 'Doctor,' 'Physician,' 'Surgeon,' 'M.D.' or any other word or abbreviation to his name, indicative that he was engaged in the treatment of human ailments as a business, by unlawfully signing his name 'Shaver, M.D.' . . ." The defendant urged that the information was defective in that the allegations of each count were stated disjunctively. The general rule, said the Supreme Court, is

that charging more than one of several acts in the disjunctive renders the indictment defective for uncertainty. If a defendant is charged in the disjunctive only, there is no definite statement of any fact which constitutes a violation of the law, and the accused is not apprised which charge he is required to meet. But, the court said, in the present case the first count, after alleging several acts in the disjunctive, proceeded with a specific charge, namely, that the defendant prescribed the taking of tablets internally. Likewise, the second count concludes with a specific charge, that of unlawful prescribing. In the same manner the third count, after several disjunctive allegations, makes them specific with the phrase "by unlawfully signing his name 'Shaver, M.D.'" If an information, after disjunctive allegations, reduces them to a specific charge, it is sufficiently definite to charge a violation of the law and to inform the defendant of the nature of the charge against him. In the opinion of the court, the information was sufficient.

The evidence, the court continued, showed the defendant's guilt beyond any reasonable doubt. The health and lives of the people are of the utmost importance. The medical practice act was enacted to safeguard them to prevent their being jeopardized by the very things disclosed by the record in the present case. There were no mitigating circumstances shown, and, in the opinion of the court, a smaller penalty would but tend to condone a grave offense. The punishment was considered therefore not excessive.

The judgment of the appellate court, affirming the conviction, was sustained.—*People v. Shaver (Ill.)*, 11 N. E. (2d) 400.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1927 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

*Use of New Antispasmodic Drug in Gastroenterology: Preliminary Report. M. Einhorn, New York.—p. 121.

Antispasmodic Drug in Gastroenterology.—Einhorn substituted diphenylacetyldiethylaminoethanol ester hydrochloride for tincture of belladonna in the treatment of eleven cases of duodenal ulcer, one of gastric ulcer, one of diverticulum of the duodenum, one of cardiospasm, three of cholecystitis, five of colitis (spastic of mucus), one of hyperacidity and one of acute intestinal obstruction. All the patients were free of side effects, such as dryness of the mouth, dilatation of the pupils, palpitation and irregular pulse. No definite relief of pain was reported in the cases of cholecystitis. The results were poor because the pain was intimately associated with the inflammatory process rather than with a spasm. No results were obtained in the cases of cardiospasm because cardiospasm is not a true spasm of the cardia. Good results were obtained in the remaining cases. The patients were relieved of their pain, although this relief cannot be attributed entirely to the drug, since it was used in conjunction with other medication (diets, alkaline powders, and the like). Excellent results were obtained in certain cases in which hiccup was present. This complaint disappeared completely about twenty minutes after the drug was administered intramuscularly. There were no toxic effects, even when the drug was administered over a long period.

The Lucid Interval and Acute Appendicitis. J. O. Bower, Philadelphia.—p. 529.

Treatment of Encephalitis with Benzedrine Sulfate.—Matthews enumerates the clinical results observed in twenty patients with chronic encephalitis having a parkinsonian syndrome treated with benzedrine sulfate (benzylmethylcarbinamine), eighteen of whom have been receiving the drug by mouth for a period of from six to twelve months. Fifteen patients have shown definite sustained improvement which must be attributed to benzedrine alone, since no change was made in the medical regimen which was previously being carried out. Oculogyric crises were controlled or diminished in frequency and severity in five of six patients. In two patients with myoclonus of the eyelids the symptom was greatly benefited. Thirteen patients have manifested a distinct improvement in mood, have become more cheerful and state that they have more energy. There has been a lessening of rigidity and tremor in a number of patients but this has not been constant and is difficult to evaluate clinically. In four cases salivation has become less troublesome. The results have been encouraging and suggest further investigations. Patients repeatedly reported an aggravation of symptoms when they were without the drug for a few days. Benzedrine enhances the effect of stramonium, atropine and scopolamine and is best used in conjunction with these drugs in the treatment of postencephalitic parkinsonism.

Circulatory Effects of Tobacco and Nicotine.—Experimental and clinical studies supporting the thesis that chronic tobacco or nicotine poisoning leads to degeneration of circulatory organs are poorly controlled and therefore of doubtful value. Experiments of Thienes and Butt show greater vascular degeneration in control animals than in animals chronically poisoned with nicotine. They suggest that acute peripheral vasoconstriction associated with smoking may exaggerate the effect of existing vascular disease on the nutrition of the extremities. Smoking probably does not produce organic disease of the heart. A recent study by Harkavy emphasizes the insecure ground of prescribing "nicotine-free" tobacco for persons who have Buerger's disease. Staemmler reported that he found no vascular lesions in rats chronically poisoned with nicotine, although the adrenals and the testes were markedly affected.

Progesterone in Habitual Abortion.—Elden treated eight cases of habitual abortion with from 10 to 44 international units of progesterone during the first six lunar months of pregnancy. No other form of endocrine therapy was used. There was one failure due to an operative laceration of the cervix, and one is not as yet accounted for. Half of the patients had spotting, and one had spotting with cramps. All except one of the infants were apparently normal. Smaller amounts of the glandular product than one unit weekly may be sufficient to carry a pregnancy to term.

Trichomonas Vaginalis.—In order to test the relative merits of the cultural method and direct examination, Magath performed 250 consecutive examinations for the presence of Trichomonas vaginalis. The method of collecting the specimens was to insert two sterile cotton swabs into the vagina and rotate them several times. One was then shaken off in a drop of physiologic solution of sodium chloride on a slide, and a cover glass was applied. Search was made under a magnification of 100 diameters for from one to three minutes. Higher magnification was used for verification. The other swab was plunged into a tube of medium and the tube, with its swab, was incubated for twenty-four hours, after which time wet preparations on slides were made and examined. The results show that the cultural method possesses no advantage over a careful direct examination of the vaginal secretion. Even if both methods are used on each specimen only an occasional additional positive observation will result, not enough to justify the additional time and expense involved in the cultural method.

Ventricular Changes Caused by Tumors of the Brain.—Stone and Schulze present an analysis based on a review of the observations in forty-eight cases in which ventricular studies were made and in which the exact position of the lesion was determined by a subsequent operation or postmortem examination. In forty of these the air was injected directly into the ventricles (pneumoventriculography) and in eight it was injected by the lumbar route (encephalography). The anatomic positions of the lesions were as follows: frontal lobe twelve, motor cortex three, parietal lobe five, occipital lobe six, temporal lobe seven, corpus callosum two, third ventricle four, midline basal five and subtentorial four. The author concludes that nearly all tumors of the cerebral hemispheres cause more or less displacement of the anterior horns and bodies of the ventricles and of the septum pellucidum to the uninvolved side. Such displacements are diagnostic only of the side of the tumor. A displacement of the septum pellucidum to a greater extent than that of the third ventricle is diagnostic of a tumor arising in the frontal lobe. A displacement of the third ventricle to a greater extent than that of the septum pellucidum indicates that the tumor lies in the parietal, temporal or occipital lobe. Posterior displacement of the anterior horn is diagnostic of a tumor arising in the frontal lobe. Depression, with blunting of the superolateral angle of the body of the ventricle, is characteristic of a tumor arising in or near the motor area. A localized depression of the superior surface of the vestibule and the adjoining portion of the body of the ventricle is seen only in tumors involving the parietal lobe. Anterior displacement of the vestibule is indicative of a tumor of the occipital lobe. A complete or partial obliteration of the temporal horn is indicative of tumor involving the temporal lobe, but displacements of the temporal horn may be caused by tumor of other lobes. An acute angulation of the superolateral angle of the body of the ventricle which points superiorly and laterally is found in tumors of the frontal

and temporal lobes. A separation of the lateral ventricles indicates a tumor involving the corpus callosum.

Roentgen Therapy of Nasal Sinusitis.—Hodges shows the value of the roentgen ray as a therapeutic agent in the treatment of carefully selected cases of infections of the nasal accessory sinuses. For fifteen years a preliminary roentgenogram was taken of the sinus of every patient sent in for an examination of the chest unless the pathologic signs found seemed to be sufficient to explain the symptoms, and in all cases in which there was an increase in the bronchovascular shadows of the lower lobe. These roentgenograms disclosed numerous unsuspected infections of sinuses. Many patients with recurring colds were allergic, but most of them showed definite pathologic changes in the sinuses. The common cold that does not clear up after a reasonable time is usually an infection of the sinuses. In the average acute or semiacute infection the routine treatment with astringents, packing, suction, washing and the like has been followed by a clearing up of the condition. In some, however, in spite of the treatment, definite changes have occurred in the sinuses, especially the formation of thick membranes and granulations. This group has responded more favorably to roentgen therapy than any of the other types. The second largest group in which roentgen therapy has been effective is one in which a cough or recurrent colds have appeared for months or years. The roentgenograms show cloudy ethmoids with marked thickening of the mucoperiosteum and some air space. Washing causes little or no change in the appearance of the antrums. Many of these will show an increase in the bronchovascular shadows at the bases of the lungs, some definite infiltration and, in the more chronic ones, early bronchiectasis. In this type of case Osmond, Manges and Rathbone have reported excellent results from roentgen therapy. In acute infections with pus in the sinuses and with dense antrums, but especially in those without too long a history of trouble, the results from roentgen therapy have been so encouraging that it should always be tried since in so many of these the rhinologist must resort to radical surgical intervention for much benefit. The following technic is usually used: 130 kilovolts (peak), 6 mm. of aluminum filter, 25 cm. distance. From 100 to 300 roentgens is given. The dose, dependent on the type of case, is given in three or four treatments in from ten days to two weeks.

Vitamin C in Rheumatoid Arthritis.—Rinehart and his collaborators analyzed the blood for vitamin C of 120 medical students as "normal" controls, fifty-eight patients with more or less classic rheumatoid arthritis, thirteen with gonorrheal arthritis and twelve with hypertrophic arthritis. They find that the level of the cevitamic acid of the blood plasma during fasting is almost uniformly lowered in rheumatoid and rheumatoid types of arthritis. In the majority of cases the blood level rises after the administration of vitamin C. Usually this rise is delayed. These data indicate the existence of vitamin C deficiency in arthritis of this type, and they believe that the data afford significant support for the thesis that chronic deficiency of vitamin C is an important factor in the etiology of the disease. Some patients appear to present a fundamental fault in the metabolism of vitamin C. The plasma levels during fasting fail to rise after prolonged administration of generous supplements of vitamin C, although the urinary excretion may be relatively high. A lowered renal threshold is a possible mechanism. Low levels of vitamin C are the rule in gonorrheal arthritis. It is suggested that deficiency of vitamin C predisposes to bacterial localization in this group and possibly also in the other groups. In the cases of hypertrophic arthritis the plasma values were almost uniformly high. Apparently deficiency of vitamin C may exist in the presence of an ordinarily adequate dietary intake.

Treatment of Vasomotor Rhinitis with Sodium Morrhuate.—Fishof uses sodium morrhuate as a sclerosing chemical in the treatment of vasomotor rhinitis. The nose is thoroughly cleansed by suction. A 10 per cent solution of cocaine hydrochloride is used to anesthetize and to shrink the

mucosa. By the use of a special double curved needle and a 2 cc. luer-lok or a tuberculin syringe from 0.25 to 0.5 cc. of a 5 per cent solution of sodium morrhuate is injected between the periosteum of the turbinate and the overlying mucosa. The needle is inserted in such a manner that it touches the periosteum. Injections may be given at several points of the turbinate on the same occasion. The slight bleeding on withdrawal of the needle is controlled by placing a piece of cotton in the nasal vestibule. From three to five minutes later suction is applied to remove any clot or secretion that may be present. The immediate effect of the injection is increased nasal discharge, difficult breathing through the nose, slight headache and sometimes a sense of fullness in the head. Dripping into the pharynx can be prevented by the use of a special needle with proper angulation. The coincident burning sensation in the throat can be neutralized by gargling with a 5 per cent solution of sodium bicarbonate. This lasts from about twelve to twenty-four hours. Thereafter there is a gradual improvement of both subjective and objective symptoms. At the end of a week a definite contraction of the mucosa and a great increase in the breathing space is observed. Cocainization of the nose is not necessary when the second or the third injection is given. These injections are given at intervals of one or two weeks. It is rarely necessary to give more than four injections. Seven cases of vasomotor rhinitis are reported in which the disease was refractory to other methods of treatment but responded favorably to injections of sodium morrhuate.

Typing of Blood and Seminal Stains.—Landé carried out the absorption test on 109 dried blood specimens and ninety-three stains obtained from seminal material, which came from subjects whose blood groups were originally known. In 94.5 per cent of the cases it was possible to determine correctly the group of the blood stains, and in 93.6 per cent of the cases this was possible with the seminal stains. The information obtained through the absorption test occasionally has been sufficient to obtain a confession from the alleged assailant. In certain cases of murder the testimony of the defendant concerning the origin of a blood stain was found to be incompatible with the results of the absorption test, and in several instances the defendant, confronted with such evidence, readily confessed and related his participation in the crime. Such situations and also those which have arisen in cases of disputed paternity in which false accusations of paternity were withdrawn after the plaintiff learned that blood tests were to be applied would bear out the practical usefulness of the absorption test, even though use of the results as evidence in a court of law may not be warranted for the time being.

Capillary Rupture with Hemorrhage in Coronary Thrombosis.—In a previous paper Paterson suggested that intimal hemorrhage is due, rather, to rupture of capillaries which are derived from the coronary lumen; that capillary rupture results both from high intracapillary pressure and from softening of the supporting stroma by atheromatous degeneration and finally because intimal hemorrhage was found at the site of occlusion in nine consecutive cases of recent coronary thrombosis, that it might be the precipitating factor in the formation of the coronary thrombus. He now presents further and more definite evidence in support of this hypothesis. Hemorrhages into the intima of sclerotic coronary arteries have been shown by study of serial sections of six cases to be intrinsic lesions and not the result of intimal erosions. They

are due, apparently, to rupture of capillaries which are derived from the coronary lumen. Intimal hemorrhages have been observed both with and without thrombosis of the adjacent coronary lumen, and in either case they are identical in structure. Intimal hemorrhage has been a common finding in recently thrombosed coronary arteries, hemorrhage of some degree having been found in thirty-two of thirty-seven consecutive cases. The microscopic observations suggest strongly that intimal hemorrhage (or the other sequelae of capillary rupture) is intimately concerned with the etiology of most coronary thrombi. If the proper conditions of stagnation and eddying of blood exist at a given point in the coronary system capillary rupture with its sequelae occurring in the same region may precipitate thrombosis. Capillary rupture may initiate thrombosis of a coronary artery by diffusion of the blood from an intimal hemorrhage into the lumen, by necrosis or erosion of the intima from damage to its capillary circulation or by retrograde capillary thrombosis. Any one or all of these factors may operate in an individual case.

Cellulose-Compound Casts in Arthritis.—Joplin used the cellulose-compound bandage (preliminary report by Thorndike and Garrey abstracted in THE JOURNAL April 16, 1937, p. 1316) for forty-two cellulose-compound casts in the treat-

ment of twenty-four patients with arthritis. In the treatment of both bed and ambulatory patients with arthritis, cellulose-compound casts and cylinders have proved a valuable adjunct to physical therapy. A patient who was bedridden with rheumatoid arthritis had ankylosis of both hips and of the right knee and was unable to sit or to stand. Arthroplasties of the left hip and knee were performed. Physical therapy was started in the Hubbard tank as soon as the wounds had healed, but the patient complained of severe pain in the left knee. All active motion was stopped until a cellulose-compound cylinder was applied. With this waterproof, light-weight support, painless exercise under water was carried out regularly and effectively. In the treatment of aged patients with osteo-arthritis and ambulatory patients with arthritis of the knees whose joints are quiescent when the patients are recumbent but become swollen and painful on attempted walking, so-called walking cylinders have been used with excellent results.

Traction Treatment of Sacro-Iliac Strain.—Warner has found the following contrivance simple, convenient and practicable for home treatment of sacro-iliac strain. The inner tube of a tire is placed round the footboard of the bedstead at the level of the upper surface of the mattress. Two loops, about 8 inches in diameter and made of canvas tape or a trouser belt, encircle the inner tube perpendicular to its length. The feet of the patient are placed in the loops, so that the tape hooks above the ankles, the calcaneal tubercles and the toes. The two loops are about 18 inches apart. The foot of the bed is elevated into reverse Fowler's position, and the patient pulls himself toward the dependent head of the bed sufficiently to apply tension on the rubber inner tube. In this way the patient's body weight opposes the pull of the inner tube. This position can be maintained for hours at a time without discomfort to the patient. It will usually be found necessary for the patient to pull himself to the head of the bed every once in a while, as the inner tube pulls him the other way.

Purification of Air by Spraying or Atomizing.—Masterman carried out experiments to test the bactericidal effect of spraying dilute hypochlorite in room air. Chemical experiments showed that heating such a solution failed to promote the production of hypochlorite beyond that already in the solution. Bacterial deposits on Petri dishes with and without the hypochlorite spray showed that the hypochlorite caused a reduction in the bacterial count up to 90 per cent in a few hours. A control experiment in which plain water was sprayed gave a reduction of only 32 per cent after five hours. This method offers a cheap and effective procedure for the purification of air in occupied rooms. The active chlorine in the solution was 10.8 Gm. per liter.

Postmortem Observations in Trichinosis.—Schapiro and his associates correlate the response of the intracutaneous skin test of Bachman with that of postmortem observations in trichinosis. In the entire series of 400 cases the cutaneous test failed to detect the presence of trichinae in only two instances; both cases, on diaphragm examination, being found to be lightly infested, long-standing cases. Of the seventy-three cases which showed a positive cutaneous test, three were found to be negative at necropsy. Statistically, these values may be interpreted as indicating that for the diagnosis of positive cases the test is of value in 89 per cent of the cases, whereas as a negative test it is of value in 97.8 per cent of the cases. The three cases which responded positively to the cutaneous test but were found to be negative at necropsy may be explained as false positives, possibly because of parasitism by related nematodes or because of a nonspecific type of reaction. The exact cause of false positives is not understood and needs further study. However, the incidence in this series is enough to condemn the test. Another and more logical explanation of these three cases is that in some instances the infestation may be so light as to be missed entirely on microscopic examination. Furthermore, encystment may occur in muscles other than the diaphragm and thus escape detection on necropsy. The two false negatives are not so easily explained. Individual peculiarities in the immunologic response to the presence of foreign protein in the body must be considered. Since there was light infestation in both cases, it may be assumed that the antigen used was too dilute to detect such light sensitivity. On the other hand, in long-standing cases of light infestation the individual tendency may be toward a complete loss of sensitivity. The relationship of the wheal reaction in the skin to the extent of eosinophilia and to the changes in the diaphragm was quite consistent throughout the entire series. The correlation between the extent of the cutaneous reaction and the degree of eosinophilia in the patient indicated a higher degree of eosinophilia in those cases in which a strong cutaneous reaction (more than 10 mm. in diameter) was produced.

Physiologic Actions of Benzedrine Sulfate.—Ten typical protocols are presented by Davidoff and Reifenshtein to illustrate some of the physiologic actions of benzedrine sulfate studied clinically. Unpredictable increase or decrease in both the systolic and the diastolic levels occurred together or independently. Increased levels are more frequent. Increase or decrease in pulse rate occurred, not necessarily concomitant with blood pressure variations. Arrhythmias were observed occasionally. There was an increase or decrease in the fre-

quency of urinary action and an increase or decrease in the amount of excretion. A decrease in body weight occurred in most subjects with an occasional marked increase following discontinuance of the drugs. The changes of the skin, mucous membranes and vasomotor system included flushed face, sweating of the hands, greasiness of the skin, dizziness, dryness of the mouth, injection of the conjunctivae, increase in nasal secretion, palpitation and precordial pain. There was a slight increase or decrease in temperature. The basal metabolic rate was more often increased than decreased, but there was no consistent variation. It is recognized that there is variability in the action of both the sympathomimetic and the parasympathomimetic drugs. Benzedrine sulfate appears to be no exception to this. Its unpredictable action suggests that the response of each individual to the drug tends to vary, depending on the interaction of a number of factors rather than on the peripheral action alone. Among these factors might be included the physical constitution, endocrine status, personality makeup, psychologic reaction, existing mechanisms and complex formations and the state of the entire nervous system.

Low Protein Antitoxins in Scarlet Fever.—Recently purified and concentrated scarlet fever antitoxins have been manufactured by three different biologic laboratories. All these antitoxins have been used by Toomey and Baker. They have treated 800 cases with one antitoxin, termed antitoxin 1, ninety-two cases with antitoxin 2 and thirty cases with antitoxin 3. The various antitoxins were not available at the same time. Hence the number of cases treated with each kind of antitoxin is not comparable. It was found that the serum reaction rate following the administration of two of these

antitoxins was decidedly decreased as compared with the high serum reaction rate following the use of the old type of scarlet fever antitoxins.

Fever Therapy for Chorea.—Sutton and Dodge compare the results of ninety-nine children who were given fever therapy for chorea to sixty who did not receive this treatment. All of these patients were seen in the first attack, and most of them in recurrences. The first group is composed of forty-eight treated and twenty-three untreated patients whose observation period was from one to three years. The second group consists of fifty-one treated and thirty-seven untreated patients observed from four to six years. The most striking differences are the higher incidence of polyarthritis and deaths from heart disease in both observation periods among the untreated cases. None of the treated patients observed from one to three years had aortic lesions, whereas one of the untreated patients did. In the group observed from four to six years aortic disease developed in one patient compared to six in the untreated group; that is, of those who had organic heart disease in the group observed from one to three years none of the treated patients had aortic disease compared to 16½ per cent in the untreated. In the group observed from four to six years 6½ per cent of the treated group who acquired heart disease had aortic lesions, compared to 46 per cent of the untreated. If these observations are valid the reason may be that the infectious process is inhibited by fever. If fever therapy does modify the course of rheumatic infection in those patients who receive it, it is a far more important therapeutic procedure in this disease than if its value is confined to shortening an attack of chorea.

Treatment of Hemolytic Streptococcus Meningitis with Sulfanilamide.—From 1924 to 1936 Silverthorne and Brown treated ninety-three patients with meningitis due to the hemolytic streptococcus. These patients were treated by one or more of the following procedures: spinal drainage, intravenous dextrose-saline injections, scarlet fever antitoxin and mastoidectomy when indicated. There was only one recovery. Nine patients with streptococcal meningitis during 1937 have been treated with sulfanilamide, a continuous intravenous injection of dextrose-saline injection and daily spinal puncture with drainage. Mastoidectomy was performed in six of the nine cases in which mastoiditis was present. Five of these nine patients have recovered. It is the authors' belief that sulfanilamide has been chiefly responsible for the recovery of these patients.

Hypertension and Its Surgical Treatment.—Craig states that 136 patients with hypertension have been operated on in the Section on Neurologic Surgery at the Mayo Clinic by means of subdiaphragmatic extensive sympathectomy, without an operative death and with only four subsequent deaths. Clinical improvement after operation varied according to the progress of the disease, the age of the patient and the amount of vascular cardiac and renal damage. Suitable preoperative tests have been devised to measure the amount of potential physiologic response to sympathetic denervation, and these tests have prevented unsuccessful operations and indicated those cases in which a sufficient lowering of the blood pressure or relief of clinical symptoms would take place to make operation justifiable. Operation is advised only for patients whose blood pressure responds satisfactorily before operation to: 1. The slow and intermittent intravenous injection of a 5 per cent solution of pentothal sodium (sodium methylbutyl thiobarbiturate) until there is no further drop in the blood pressure; ordinarily from 500 to 1,000 mg. is injected. 2. The administration of 3 grains (0.2 Gm.) of sodium amytal each hour for three successive hours. 3. The administration of half a grain (0.032 Gm.) of sodium nitrite at intervals of half an hour until six doses have been given. 4. Hourly determinations of blood pressure during rest and sleep for a minimum of twenty-four consecutive hours. If the blood pressure decreases to normal or to nearly normal as a result of all these measures, the patient may be considered a satisfactory candidate for operation; if not, the effect of operation is almost certain to be unsatisfactory. Operation is contraindicated when the patient is more than 50 years of age and has congestive heart failure, angina pectoris, marked renal insufficiency and/or advanced arteriosclerosis.

Muscle Flaps for Closure of Empyemic Cavities.—Carter emphasizes that adequate drainage by the resection of long segments of several ribs and wide exteriorization of the empyemic cavity is the most important step in the treatment of chronic empyema and calls attention to the advantage of using pedicled flaps of muscle in the closure of the chronic empyemic cavity that remains after adequate drainage has accomplished all it can. The procedure used to obliterate the cavity which persists after thorough drainage and active treatment will depend on the type, the size and the location of such a cavity. The large cavities in the lower portion of the thorax, cavities that lie beneath the scapula and those at the apex of the thoracic cage cannot be closed easily. In these instances flaps of muscles can be swung into the cavity in order to obliterate it. The muscles which are available for this purpose are the latissimus dorsi, the trapezius, the sacrospinalis and the pectoralis. In order to get enough material to fill the cavity it is important that one plan the operation so as to utilize every bit of muscle possible. A useful method of obtaining added bulk of muscle is to make a second incision at right angles to the one which has been placed at the lowermost border of the empyemic cavity, to reflect the cutaneous flaps thus formed, and to cut the muscle which is to be utilized at a considerably lower level. In this way several inches of muscle may be gained. The intercostal muscles should be carefully preserved when possible and likewise utilized as a "fill." They are especially useful to plug bronchial fistulas. If the cavity is not too deep, they may be preserved intact (not divided) and allowed to fall into the floor of the cavity. The thick parietal pleura, because of probable small abscesses and infected sinus tracts, should be excised rather than utilized as material with which to fill the empyemic cavity. Another reason for its excision is that in tuberculous empyema (from 10 to 13 per cent of chronic empyemas) the parietal pleura practically always is the site of tubercles or tuberculous granulating tissue. Unless the empyemic cavity is large, relatively little deformity is present after the operation. The author has found the use of pedicled flaps of muscle to be satisfactory in dealing with the persistent chronic empyemic cavity, in the closure of extrapleural cavities resulting from the excision of cold abscess of the wall of the chest, in the cure of chronic abscesses of the lung and in the secondary closure of infected thoracoplasty wounds in which an extrapleural cavity remains beneath the scapula.

Blood Index in Pulmonary Tuberculosis.—Nathan applied the blood index of Houghton (depending on the sedimentation rate, the von Bonsdorff count and the polymorph-lymphocyte-monoocyte ratio) in order to determine the prognosis of pulmonary tuberculosis in women. Of the eighty cases taken for consideration, fifty-six gave results the summation of which pointed to an immediate prognosis similar to that deduced from the clinical, roentgenographic and laboratory observations. The remaining twenty-four cases gave divergent readings, thirteen of which showed marked variation during the menstrual stage. Of the remaining eleven cases no reason for the inconsistency in the readings could be found. In thirty of the cases a depression in the index occurred, due to hemoptysis in 10 per cent, to a spread of disease in 74 per cent and to fluid occurring in an artificial pneumothorax in 16 per cent. The blood index always appeared to rise the month following the patient's admission to the sanatorium, during which period she was confined completely to bed. A sudden fall in the blood index should therefore be regarded as an alarming signal. The best time to obtain samples of blood has been found to be immediately after the cessation of the menstrual period, as fluctuations may occur during the premenstrual stage.

Infection with Actinomyces Caprae.—The patient from whom the Gibsons and Rose-Innes isolated *Actinomyces caprae* was one of two with acholuric jaundice. They are unable to explain the occurrence of *Actinomyces caprae* in the cultures from the excised spleen of case 1 except as a pathogenic agent in intimate relation to the splenic tissue. It is inconceivable that it could have been an accidental invasion or contamination. The number of cases however (now thirteen) from which

actinomyces has been obtained from the excised spleen or liver in acholuric jaundice, splenic anemia and Banti's disease makes it probable that the present organism bears an etiologic relation to the disease. This appears to be the first occasion on which *Actinomyces caprae* has been found in a human case. A thin emulsion, however, made by continual shaking of a twenty-four hour broth culture showed no agglutination as tested against the serum of case 1. The serum added to a broth culture of the organism increased the rate of growth and brought out more prominently the characteristic color of the organism as compared with six normal control serums. The siderotic nodules in the spleen on first exposure were a buff color, but on being incubated in culture tubes under aerobic conditions they assumed the same tint as an old culture on agar. Splenectomy in both cases had the effect of completely relieving the jaundice, restoring the hemoglobin and number of red corpuscles to normal and diminishing the fragility. It is concluded that *Actinomyces caprae* was an essential pathogenic agent in the production of the disease.

Cullen's Sign in Antepartum Rupture of Cesarean Scar.—Gerrard cites a patient who three years previously had been delivered for the first time by cesarean section of the upper segment after an extended trial of labor. The child was still-born and the puerperium was difficult. Her present pregnancy had been uneventful up to the thirty-sixth week, when she began to feel pain in the lower part of the abdomen. Two days previous to the author's seeing her she had had an attack of acute cutting pain which lasted for about four hours. Shortly afterward she noticed a reddish stain at the umbilicus. There had been no vomiting, and as she walked into the clinic for her fortnightly antepartum examination her only complaint was of a slight feeling of soreness. On examination her general condition was found to be excellent. The umbilicus showed a reddish purple stain about the size of a shilling. On palpation the child was found to be lying in a left sacro-anterior position. Despite the patient's excellent condition the presence of Cullen's sign was deemed to indicate intraperitoneal hemorrhage, and a diagnosis of a ruptured cesarean scar was made. The abdomen was opened through a right paramedian incision. On retraction of the rectus the peritoneum in the umbilical region was seen to be infiltrated with blood. Incision of this structure revealed no free blood in the peritoneal cavity, but a clot of blood about 2 inches long and 1 inch broad was found attached to the old uterine scar. The clot was removed, exposing a tear about 1 inch long which had been effectively plugged by the placenta, which was lying immediately beneath it. The site of rupture was extended upward and downward and the child was removed. It breathed a moment or two later. There was profuse hemorrhage, but the uterus retracted well after the placenta was removed and an injection of solution of posterior pituitary and ergometrine was given. The author is inclined to think that in his case there must have been damage to the peritoneum at the time of rupture of the uterine scar due to the clot of blood and the attachment of the placenta to the anterior wall of the uterus.

Incidence of Bronchiectasis in Asthma.—Fifty consecutive cases of asthma, of a duration varying from three to ten years, were investigated by Viswanathan in order to find out the incidence of bronchiectasis. Roentgenograms of the lungs, after iodized poppyseed oil was injected into the bronchi, were taken. Fourteen cases showed definite evidence of bronchiectasis. Six showed saccular dilatation, five cylindric dilatation and three early bronchiectasis with tortuosity of bronchioles and slight cylindric dilatation. In ten of the fourteen cases there was clinical evidence of chronic bronchitis with asthma. But the history was suggestive of the primary condition being asthma. The author suggests that during an asthmatic attack there is a considerable increase in the inspiratory pull on the bronchial walls, particularly on those portions which are weak congenitally or weakened by inflammation. The spasm of the healthy portions of the bronchial wall will only accentuate the irregularity of its contour.

- *Incidence of Brucellosis Clinical and Latent Among Various Groups of Population. C. P. Beattie.—p. 260.

Cross Infection in Diphtheria Wards.—Glass and Wright show that cross infection occurred in 36.6 per cent of 246 patients in diphtheria wards. In patients who were in the hospital longer than two months it occurred in 68 per cent. Persistence of diphtheria bacilli in the upper part of the respiratory tract was responsible for prolonged hospitalization in 76 per cent of the cases. In 80 per cent of these cases this persistence was a result of cross infection. The results indicate that cross infection in the diphtheria wards of hospitals for infectious diseases is not uncommon. To the patient admitted in error to a diphtheria ward it offers certain dangers and this provides an argument for the reception of dubious cases into special observation wards. To the diphtheria patient, however, reinfection appears to be associated with little or no risk in contrast to reinfection with scarlet fever streptococci. From the point of view of hospital administration cross infection is a matter of considerable importance. The difficulty of cross infection might be overcome by hospitalizing the patients in different wards according to the type of infecting organism.

Incidence of Brucellosis.—Beattie records certain observations on the relative frequency of *Brucella* infection in different occupational classes and correlates this with the path

(ingestion and contact) of infection and the dose of organisms. The first group that he considers is the population as a whole. Infection among them must, in this country, be mainly by ingestion. The opportunity for infection is great since from 20 to 35 per cent of raw milk contains *Brucella abortus*. The organism is, of course, killed by efficient pasteurization. In England and Wales from 1928 to 1935 Dalrymple-Champneys (1935) recorded 255 cases of undulant fever. In Scotland, from 1929 to the end of 1935, 108 cases have been reported by the author and others. Nor is latent brucellosis common. Serums submitted for the Wassermann reaction have been tested for the presence of agglutinins for *Brucella abortus*. Cruickshank and Barbour found 2.4 per cent to react in a titer of 1:20 or higher, Smith 4.6 per cent and Tulloch 2 per cent. The reasons for this low incidence of infection may be that, although a large proportion of milk contains *Brucella abortus*, the concentration of the organism is not high and ingestion is not the most dangerous route of infection. An examination of the serums of thirty-seven farm workers, slaughterers and butchers showed agglutinins present in two in a titer of 1:25. This shows that the incidence of brucellosis among slaughterhouse workers and possibly among farm workers is somewhat greater than the incidence among the population as a whole. Members of the veterinary profession run a great risk of contracting infection when they engage in the removal of placentas or assist in calving, yet few show clinical signs of infection. Of 108 cases of undulant fever recorded in Scotland only one was in a veterinary surgeon. In England and Wales Dalrymple-Champneys has heard of two veterinary surgeons and one veterinary student who have contracted undulant fever out of a total of 314 cases. When specific inquiries have been made among groups of veterinarians as to the previous occurrence of an illness having the clinical features of undulant fever, more cases have been disclosed. Thus of forty-nine practicing veterinarians in the United States Huddleson and Johnson considered that three had previously had undulant fever. Jordan found three out of 120. Thomsen in Denmark from among twenty-nine recent graduates found three who had a disease of the symptomatology of undulant fever, and among 182 veterinary students the author found one who definitely had undulant fever and two who gave a history which, combined with a high serum agglutination titer, warranted a retrospective diagnosis of undulant fever. He has examined the serums of students attending a veterinary college. In many cases the examination was repeated in subsequent years. Of the postgraduate students 58.3 and 10.8 per cent of the undergraduate veterinary students were found to have agglutinins for *Brucella abortus* in their serum. This should be borne in mind when a diagnosis of undulant fever is considered in a member of the veterinary profession.

Thrombosis of Central Vein of Retina.—Holmin and Ploman observed the gradual return of vision in an eye with a thrombosis of the central vein of the retina, after treatment with heparin. The patient was given intravenous injections of heparin. On the tenth day of treatment the patient had no

subjective symptoms. Delimitation of the papilla was only slightly indistinct. The veins were somewhat dilated. Papillary hemorrhages were still visible, though reduced in size, paler and thinner. Otherwise there were no hemorrhages anywhere in the fundus. Vision was 0.9 (—0.5) and a month later 1 (—0.5).

Thrombosis of Cerebellar Artery.—Magnusson treated with heparin a severe case of Wallenberg's syndrome—i. e., a thrombosis of the left posterior-inferior cerebellar artery, with a lesion of the circumferential and intermediate zones of the medulla oblongata. The patient was given intravenous injections of 150 mg. of a 5 per cent solution of standard heparin. No reaction followed this or subsequent injections of the same dose given three times a day for five days. The patient's condition continued to improve steadily though slowly. Two months after being taken ill she could walk up and down the hospital passage with support, and diplopia was no longer present. In another month she could just walk up and down the passage without support. Romberg's test (aggravated) was negative. The paresthesia remained but was less pronounced than formerly. Sensitivity to pain and heat and cold appeared to be normal only in the right half of the chest and abdomen and in the upper part of the right arm. Considering the usual prognosis in the disease, it is striking how rapid the improvement was after the heparin treatment. The possibility that the effect was due to suggestion is excluded by the mental condition of the patient.

*Partial Gastrectomy in Treatment of Peptic Ulcer. A. Radford.—p. 213.

Partial Gastrectomy in Peptic Ulcer.—Radford believes that operation in peptic ulcer should be considered only when (1) competent medical treatment has failed to produce healing or relapse has occurred after such treatment, (2) severe or repeated hemorrhage occurs, (3) economic circumstances are such that the patient is unable to carry out suitable dietetic care, (4) pyloric obstruction exists and (5) jejunal ulcer exists. He suggests six possible procedures: gastrojejunostomy, pyloroplasty or gastroduodenostomy, partial gastrectomy, fundusectomy, cholecystogastrostomy and jejunostomy. He thinks that partial gastrectomy is the operation of choice in peptic ulcer and that gastrojejunostomy should be reserved for patients with cicatricial pyloric stenosis or those who from age, debility or other cause are judged unsuitable for the major procedure. He has performed the operation forty-five times in peptic ulcer with two deaths—one from hyperthyroidism and one in a syphilitic patient on whom it would have been wiser to perform gastrojejunostomy, owing to his advanced age. He performs the operation recommended by Finsterer, in which the upper half of the gastric opening is closed and the anastomosis made to the lower half, the efferent loop leaving the greater curvature and the afferent loop attached to the upper

closed portion of the stomach so as to direct the current of food downward. The operation should not be performed under general anesthesia. Under local and splanchnic anesthesia there is a maximum of operative facility and a minimum of risk.

Therapy of Pernicious Anemia.—Okada and his associates, after directing attention to the importance of liver and stomach therapy in the therapy of pernicious anemia and to the fact that histamine-like substances contained in these organs exert a hemopoietic action, point out that such histamine-like substances are found not only in animal tissues but also in plants; for instance, in spinach. An extract of spinach with histamine-like action was found to stimulate the gastric secretion and the hemopoiesis. It was decided to use this extract and a spinach powder in the treatment of a severe case of pernicious anemia. At first the patient was given daily 1 Gm. of spinach powder and three injections of 0.7 cc. of the spinach extract. These doses were gradually increased to 5 Gm. of spinach powder and 4 cc. of spinach extract. Under the influence of this treatment the hemoglobin content and the erythrocyte count increased greatly, but only to a certain point. When reduced iron was added to the spinach treatment, only a temporary improvement was noted. Since a further increase in the dose of reduced iron was not tolerated, the patient was treated with gastric juice, obtained from a healthy subject according to Castle's method, and with beef. To this treatment the erythrocytes responded with a further increase. The authors reach the conclusion that the efficacy of liver and stomach therapy can be further improved by combining them with spinach therapy.

Studies on Sclerosis of Pulmonary Artery. A. Oszaeki.—p. 320.

Action of Insulin on Langerhans' Cells.—Aubertin and his associates found that repeated insulin injections produce in the pancreas of dogs an enrichment in insular tissues. This becomes manifest in an augmentation of the number and size of the islands and in the production of diffuse exocrine changes. The enrichment appears chiefly at the level of the head of the pancreas and is especially noticeable during the first months. The authors further found that repeated injections of insulin cause an increase in the pancreatic insulin content. This increase is most noticeable during the first few months of the treatment. They also investigated the mode of action of the repeated insulin injections on the anatomic and functional state of the endocrine part of the pancreas, giving especial attention to the question whether the injected insulin produces a state of rest in the insular organ which consecutively stores its own endogenous insulin. They found that this does happen. They point out that there are two tendencies in the manner in which insulin therapy is applied in diabetes: the first aims to reestablish and to maintain the general condition without concern for the values of glycosuria and glycemia and consequently does not insist on an exact parallelism between diet and insulin dosage; the second seeks to regulate the nutrition not only from the clinical but also from the chemical point of view by suppressing the glycosuria and by maintaining the glycemia near the normal level, which can be done only if the insulin dosage, in each particular case, is rigorously adjusted to the diet. The authors believe that the first method, which tends in general to transform a consumptive diabetic patient into a florid one, does not expose the patient to the complications of the latter.

*Studies on Metabolism of Vitamin C: Values of Basic Ascorburia in Course of Normal Metabolism. M. Vauthey.—p. 230.

"Cholecholecystitis": Duodenal Transcholechoal Alimentation. A.-J. Bengolea and S. C. Velasco.—p. 236.

Studies on Vitamin C: Ascorburia in Normal Metabolism.—Vauthey says that vitamin C metabolism has been studied chiefly during various infections and intoxications but not so much on normal persons. Consequently he observed during several consecutive months a normal subject, weighing 65 Kg. and receiving a sensible diet with the constant vitamin C content. The determinations which were carried out were the quantity of the urine eliminated during one hour, while the person was fasting and the pH of this urine and the vitamin C content in milligrams per liter. The author says that he employed the chemical technic of Tillmans (determination of reducing power). In this report he limits himself to the description of his investigations on the so-called basic ascorburia. He applies the term "basic ascorburia" to the hourly secretion while the person is fasting; that is, to the quantity of cevitamic acid excreted in the urine during one hour while the subject is fasting. The test is made on the urine that is eliminated one hour after the first matutinal micturition. The author cites the following example: If the volume of the urine eliminated during the hour is 64 cc. and the cevitamic acid content is 15 mg. per thousand cubic centimeters, the basic ascorburia is 0.96. The tests were made on five consecutive days and then the average was determined for the five day period. The five day period tests were repeated ten times during different seasons of the year. In evaluating his procedure, the author says that it eliminates three important sources of error: (1) the daily variations of the content per liter, by the introduction of the notion of fasting ascorburia and the notion of the hourly fasting excretion, (2) the daily variations of basic ascorburia

by the establishment of averages for five day periods and (3) the seasonal fluctuations of the vitamin C metabolism by the establishment of a general average from ten averages determined in different seasons. He reaches the conclusion that the basic ascorburia, determined according to the described method, may be regarded as a physiologic constant. It can be employed for the determination of the vitamin C content of the organism and for the detection of a latent hypovitaminosis.

Rickets and Spasmophilia. L. Plumier.—p. 435.

*Detection and Repression of Drunkenness in Drivers of Automobiles. A. Hougardy.—p. 446.

Detection of Intoxication in Motorists.—Hougardy shows that the detection of drunkenness in motorists involves two factors: the clinical examination of the suspected person and the determination of the alcohol content of the blood and urine. The clinical examination is practiced nearly everywhere, but Sweden is the only country in which it is thoroughly standardized. The author reproduces the questionnaire that is in use in Sweden and then cites the regulations that are in force in some other countries such as Norway, Germany and Switzerland. In the second part of the paper the author takes up the determination of the alcohol content of the blood. He briefly describes the most widely used method, that of Widmark, and mentions several others. However, he shows that the alcohol contained in the blood does not represent the total alcohol content of the tissues and even less the total quantity of alcohol ingested. The retention of alcohol varies not only in different persons but also in different tissues. In discussing the relation between the alcohol content of the blood and the degree of intoxication, the author cites the figures given by several investigators and shows that there are considerable disparities. He also shows that, whereas in some countries the legal regulations on intoxication in motorists contain definite figures on the relation between alcohol content and intoxication, in the regulations of other countries nothing definite is stated about this point. On the basis of this survey, the author concludes that the action of alcohol on the organism depends on a number of factors, such as the physical status of the subject, particularly the condition of the gastrointestinal tract (absorption) and of the kidneys (elimination). Another important factor is the concentration of alcohol in the consumed drink. The presence in the drink of substances that stimulate or depress the action of the motor, psychic, vasomotor, thermoregulator and respiratory centers deserves attention, as does also the external temperature. In other words, the author thinks that about the biochemistry and physiology of intoxication the last word has not been spoken as yet and that it is premature to draw final conclusions applicable to the medico-legal sphere.

Presse Médicale, Paris

46: 609-624 (April 20) 1938

Myelogenic Leukemia Without Splenomegaly. P. Emile-Weil.—p. 609.

*Gastric Pain Studied by Viscerographic Method. C. C. Dimitriu, T. Tanasoca and A. Popovici.—p. 610.

Problem of Elimination of Bromine by the Human Organism: Importance of Chlorine Balance. Camille Chatagnon.—p. 612.

Gastric Pain.—Dimitriu and his associates studied gastric pain by means of the viscerographic method as developed by Danielopolu and applied by him to a study of gastric spasms in tabes. This technic permits of precise concomitant graphic representation of intragastric mechanical and chemical phenomena. The authors submitted forty patients with gastric ulcer to the following procedures: (1) clinical examination of pain, (2) examination of gastric chemistry, (3) roentgen examination of gastroduodenal motility, (4) concomitant examination of gastric motility and chemistry by the viscerographic method. In eighteen cases no pain could be produced during a period of remission by the following stimuli: intragastric, insufflation, intravenous injection of physostigmine, and solution of posterior pituitary, subcutaneous injections of histamine, and direct intragastric introduction of a solution (from 0.5 to 4 per cent) of hydrochloric acid. It was concluded that pain at the level of the gastroduodenal mucosa cannot be manifested unless a fully active inflammatory lesion, the predisposing factor of the pain, is present. Similar studies were made of twenty-two patients

during the period when pain was most intense for the purpose of determining the interrelation of gastric pain, gastric motility and gastric secretion. In every case pain was experienced during gastric contractions and was absent during atonic phases. In some cases pain became exaggerated as the amplitude of the contractions increased. Pain could be produced or increased if contractility was stimulated by intravenous injections of physostigmine or solution of posterior pituitary. If the acidity of the gastric secretion was already sufficiently high, further increase by intragastric administration of from 0.5 to 3 per cent solution of hydrochloric acid would induce pain, more intense in the presence of peristaltic movements. Conversely, diminution of pain, without complete inhibition of gastric contraction, followed lessened acidity of the gastric juice, effected by intragastric administration of calcium carbonate or by injection of atropine. If contraction was completely inhibited, pain ceased. The more intense the pain, the more active the inflammation and the greater the respective intensity of contractility or of acidity.

Boeck's Disease of Lungs in Siblings.—Dressler says that, since it is now almost definitely established that the disorder generally referred to as Boeck's sarcoid attacks not only the skin but other organs as well, it is better to use the term Boeck's disease, because the term Boeck's sarcoid is regarded by many as referring to isolated cutaneous lesions. He further emphasizes the fact that cutaneous lesions are not essential in Boeck's disease. After a brief reference to the involvement of the eyes and of the mucous membranes of the upper respiratory passages, he points out that changes of the bones are also likely. The hands and feet should be subjected to roentgenoscopy in all cases of Boeck's disease. The osseous manifestations of Boeck's disease are those commonly referred to as Jüngling's disease (osteitis tuberculosa multiplex cystica). The spleen and lymph nodes are likewise a comparatively frequent localization of Boeck's disease. A careful observation of the pulmonary changes in Boeck's disease revealed to Dressler that there are several types; namely, cases in which the hilus glands are chiefly involved and cases in which the parenchyma is affected either in the form of circumscribed foci or in the form of a dissemination into both lungs. He thinks that the hilar form deserves especial attention, because in his material it was the most frequent. He observed about twenty cases of this type, among which were many in which the massive tumor-like enlargement of the hilus glands was the only pathologic process. He gives detailed histories of two cases which concerned a man, aged 25, and his sister. The occurrence of Boeck's disease in siblings seems to be of some significance, for it suggests that familial factors have a part. The author stresses the negligible auscultatory aspects and the comparatively favorable general condition, in comparison with the roentgenologic aspects. Both of the siblings are able to work in spite of the extensive pulmonary changes. Of especial significance for the recognition of Boeck's disease is the behavior toward tuberculin, which the author found to be negative in nearly all cases. Not only Pirquet's but also Mantoux's reaction was negative. The author regards this anergy to tuberculin as a positive anergy and suggests that it indicates a tuberculous etiology. The course of the disorder is comparatively benign and the prognosis is usually favorable, unless the eyes or the central nervous system become involved. The author says that in a number of cases he obtained favorable results with large doses of arsenic.

Thyroid and Parathyroid in Arteriosclerosis.—Handovsky directs attention to the difficulty that is encountered in selecting animals for therapeutic experiments. Two points deserve special attention in producing a disease in animals: (1) The pathologic process must be as much as possible of a physiologic character and (2) the animal species must react neither too slightly nor too severely. The author tried to produce

arteriosclerosis by pure vitamin D. He chose dogs after it had been ascertained that their organs were free from calcifications. Three different dosages were employed. One group of dogs was given from 0.05 to 0.23 mg. per kilogram daily, a second group from 0.55 to 0.72 mg. per kilogram daily and a third group was given 3 mg. and more per dose. The treatment with the first dose was continued for 114 days and with the second dose for forty-five days. The third dosage was toxic; it rapidly produced hypercalcemia and hypercholesterolemia; moreover, within a few days grave sclerotic alterations could be produced in the renal tubules which only a few animals survived. Summarizing his observations on the different groups of animals the author says that, whereas of forty examined dogs in various stages of hypervitaminosis not a single one manifested macroscopic alterations on the aorta, the first thyro-parathyroprivic dog, which was treated for forty days with the second type of dose, showed an arteriosclerotic aorta. Moreover, this phenomenon could be reproduced a number of times; eight animals deprived of the thyroids showed these lesions of the aorta under the action of the second type of dosage. However, not only are the final morphologic lesions different: the entire process presents itself in a different manner. If, on the other hand, the thyro-parathyroprivic dogs are given injections of a thyroid preparation simultaneously with the vitamin D treatment, there are no macroscopic lesions of the aorta. Thus it is definitely proved that the arteriosclerosis in the thyro-parathyroprivic animals is attributable to the absence of the thyroid function. Moreover, the proof is furnished that the thyroid occupies a key position in relation to the alterations of the blood vessels: its hyperfunction (normal hypervitaminized animals) favors necrosis of the arterioles and inhibits arteriosclerosis; its hypofunction or total absence of its function inhibits necrosis of the arterioles and favors arteriosclerosis of the median arteries and of the aorta. In man likewise the thyroid plays a part. In this connection the author mentions the relation between myxedema and arteriosclerosis and says that, when the first ablations of the thyroid in human subjects were made, a number of cases of arteriosclerosis were observed among these patients. On the basis of several experiments which he made in order to determine the significance of the parathyroids in arteriosclerosis, he concludes that in case of diminution of the thyroid function the parathyroids may greatly favor the necrosis and the calcification of the aorta and of the large arteries.

Annali di Ostetricia e Ginecologia, Milan

60: 107-208 (Feb. 28) 1938

- Necrobiosis of Fibromyoma of Uterus in Course of Pregnancy. C. Cicci.—p. 107.
*Pregnancy and Parturition in Early Youth. G. Nicora.—p. 137.

Pregnancy and Parturition in Young.—Nicora studied 390 normal pregnant women ranging in age between 13 and 17 years. Menstruation appeared between the ages of 12 and 14 in the majority. In no case did it appear before the age of 9 or after 16 years. One woman in the group became pregnant before the beginning of menstruation. The author compares pregnancy and parturition in young girls with that of women of average age. Miscarriage takes place in about eleven of 100 cases. Delivery of premature living fetuses takes place in fourteen of 100 cases. Sympathetic phenomena develop in few cases. Heart disease, bronchopneumonia, gonorrhea and syphilis are rare complications of pregnancy in young girls. Albuminuria and eclampsia are frequent. As a rule eclampsia is of a serious type. Delivery is normal and of short duration. Dilatation of the uterus and elimination of the placenta and membranes are the stages of shortest duration. Surgical interventions in pregnancy, delivery or afterbirth are rarely necessary. The vertex presentation is the most frequent in deliveries at full term. The podalic presentation occurs in a few cases of early delivery. Transverse and other abnormal presentations are unusual. Pelvic abnormalities are rare. The joints of the pelvis of young girls have a great mobility and the contractions of the uterus are energetic. Abnormalities of the insertion and detachment of the placenta and inertia of the uterus are rare. Rupture of the perineum is more frequent but more benign in young than in older women. When it does happen, it is a first degree rupture. Puerperal

fever and septicemia are extremely rare. The mortality rate of young mothers is within the limit of the average mortality for more mature mothers. The weight of the infants at birth is slightly under normal. The mortality rate of the newborn of young mothers is high. This is because of the frequency of premature deliveries. In order to prevent abortion and premature deliveries of young mothers the author advises hospitalization in special welfare centers, to guard against overexercise. He thinks that the health of young girls is not impaired by motherhood and that their children are normally healthy.

Varices of Esophagus and Stomach: Clinical and Roentgen Study. D. Boric and S. Jankovic.—p. 413.

Acidosis in Diseases of Kidneys.—Stanojević investigated the function of the kidneys in eliminating acids or bases. In the early morning the patients were given thirty drops of diluted hydrochloric acid within three or four hours, or 5 Gm. of sodium bicarbonate within two to five hours, or both. The test was carried on in normal persons and in patients who were suffering from diseases of the kidney, with or without renal insufficiency. In all cases the tests of dilution and concentration of the urine were also performed. The amount of urea and uric acid in the blood and the xanthoproteic reaction in the blood were determined. In the group of normal persons the average pH of the urine was 6.1. There was a rapid alkalization of the urine after administration of sodium bicarbonate (a pH of the urine of 8 or 8.2) followed by a rapid elimination of alkali and a similar behavior after acid. In essential hypertonia and in chronic or subchronic glomerulitis the pH of the urine before administration of sodium bicarbonate varied between 4.5 and 5.5. The elimination of alkali in the course of the test was insufficient and retarded. The pH of the urine after administration of sodium bicarbonate was below 8 in essential hypertonia and below 7 in glomerulonephritis. The author found that the pH of the urine in renal insufficiency does not change by administration of acids. An insufficient elimination of alkali during the sodium bicarbonate test parallels an insufficient concentration of the kidney. There is a relation between the increase of uric acid in the blood and the lowering of elimination of alkali of the kidney. In the course of benign focal or diffuse glomerulonephritis the power of the kidney in eliminating alkali is almost normal. As a rule a poor elimination of alkali and a low hydrogen ion concentration of the urine correspond to an insufficient power of concentration of the kidney. There is a relation between the increase or diminution of the amount of uric acid in the blood during variations of renal insufficiency and the variations of the power of the kidney to eliminate alkali in the course of repeated sodium bicarbonate tests. The alkali test is of value in showing the function of the kidney and the condition of the acid base equilibrium. The test is more reliable than tests of the power of the kidney for dilution and concentration. It is simple and well tolerated by the patients. The author concludes that there is acidosis in renal insufficiency. The kidneys have an important part in maintaining the acid-base equilibrium of the blood and body fluids. When the functions of the kidney are impaired, a disturbance of the acid base equilibrium takes place.

*Etiology of Venereal Lymphogranuloma. G. B. Cottini.—p. 451.

Treatment of Orogenous Septicemia. V. Pescetti.—p. 454.

Behavior of Zambini Reaction in Surgical Interventions. V. Lorzio.—p. 465.

Venereal Lymphogranuloma.—Cottini believes that a granular virus which causes venereal lymphogranuloma has been identified in microscopic slides prepared from the pus of patients or in stained tissues of the brain of rats which were previously inoculated. The author describes serial histologic sections of brains of rats which were successfully inoculated with Blay,

Stendel, Schäfer or Ernstberger viruses of human origin. The viruses had had from fifteen to 155 transferences from animal to animal, when used in the author's experiments. Photographic illustrations of the sections are given in the article. The author concludes that the lymphogranulomatous virus can be shown in serial sections of the brain of inoculated rats, even if the virus has passed through several inoculating transferences. The virus is selectively located in the lumen of the cerebral blood vessels in the depths of the cerebral tissues (white matter and choroidal plexuses) or around the vessels. There are neither virus granulations in the periphery of the brain and the gray substance nor free granulations in the cerebral tissue. The number of virus granulations in the cerebral blood vessels or near them is small. The author was unable to use virus which had not passed through several animals. He believes that the passages of the virus through several animals may increase or diminish the selectivity of the virus for the brain. The virus stains about the same in microscopic sections of the brain as in microscopic preparations of fresh tissues of the structure.

*Continuous Traction on Open Stumps of Limbs. A. Torres Posse and A. A. Soljancic.—p. 687.

Erythroplasia of Vulva: Case. J. L. Carrera.—p. 694.

Continuous Traction on Open Stumps.—Torres Posse and Soljancic state that the stumps which remain open after amputation will heal by the application of continuous traction to the stump. The apparatus used by the authors is simple. Two strips of adhesive tape 5 cm. wide are placed in the form of a cross on top of which is put a cross of light wood with a hole in the center and a cord by which traction is applied. The wooden cross is slightly longer than the diameter of the thigh. The four free ends of adhesive tape are applied to the thigh from 5 cm. above the border of the stump near to the base of the thigh. The adhesive part of the tape which is not fastened to the stump is covered with a piece of bandage. A space of 15 cm. is left between the stump and the cross. The adhesive tape on the thigh is held in place by a piece of adhesive tape which is placed over it but not completely around, so that pressure is avoided. A bandage is placed on top of the adhesive tape, which is allowed to adhere to the stump for two days. Traction is applied by a convenient method with a weight of 1 or 2 Kg. Excessive pressure should be avoided, as it will cause edema. If edema appears, traction is discontinued until it disappears. A moderately active mobilization is given to the stump as soon as it is placed under traction. In treating the stump, the assistant raises it, holding it by the traction cord. The treatment is applied under the stump and the latter covered by a dressing 25 cm. long and 30 cm. wide, which is held in place either by pinning to the adhesive tape or by a bandage. Continuous traction is also indicated a day after amputation in order to obtain quick healing of the stump and also when reamputation is contemplated. This prevents retraction of the tissues, diminishes tension on the borders of the operative wounds, hastens healing and prevents or controls suppuration.

Vector Diagram of Heart as Clinical Method. F. Schellong.—p. 453.

Polarographic Investigations on Insulins. C. Tropp.—p. 465.

New Type of Insulin.—Umber and his associates say that on the basis of clinical experiences with the various types of protamine insulin and protamine zinc insulin they are able to corroborate the effective action of these preparations and their

superiority over ordinary insulin. They think, however, that the addition of protamine to the insulin may elicit hypersensitivity because protamine is a foreign protein. In this connection they point out that, according to Joslin's observations, the addition of protamine may lead to local and general irritations. It was their aim to find an insulin with a good depot action that would be free from protein or its decomposition products. They experimented with various depot insulins that were free from an admixture of protamine. Finally a preparation was found that was tolerated without irritation and the protracted action of which was at least equivalent to protamine insulin. In this preparation the protracted action is obtained by the addition of a synthetic cyclic compound, a quinoline preparation. Trials with this insulin on seventy-five patients with diabetes mellitus revealed that it had a good depot action and was well tolerated. Its protracted action corresponds to that of protamine zinc insulin. Since the protracted action of the new insulin can be regulated, further improvements may be expected.

Intermediary Fat Metabolism.—Katsch directs attention to the fact that diabetes mellitus is not a clinical entity and that quantitative estimates of the sugar metabolism, although valuable, are not sufficient for the differentiation of its various forms. He emphasizes that the disturbances in the fat metabolism of the diabetic patient are erroneously considered as mere sequels of the disorder. The internal need of sugar forces the increase in the fat metabolism. The extent and type of the disturbance in the fat metabolism do not parallel the severity of diabetes mellitus, particularly if the severity is evaluated only on the basis of the sugar metabolism. In this connection the author points out that a patient with the severest case of lipemia, among 3,000 cases of diabetes mellitus, had only comparatively mild diabetes. Dependence of the lipid metabolism on endocrine factors (thyroid and ovary) reveal constitutional peculiarities, which have an increased significance in diabetic patients. The same can be said about the lipid metabolism with regard to its relation to parenchymal impairment of the liver and kidney. The problem of the fat content of the diet of diabetic patients is much discussed today. Moreover, the predisposition to ketosis is of great importance. The first of the investigations on these problems were those described by Krainick in the following paper.

Ketone Bodies in Blood.—Krainick says that, in order to gain an insight into the finer mechanism of the intermediary fat metabolism, analytic methods are needed which are not only simple and exact but require only small quantities of capillary blood. For the detection of relations between the fat and carbohydrate metabolisms, the determination of the ketone bodies in the blood is of great importance. For the quantitative determination of acetone in small amounts of blood the author took the Fabinyi-Fronmuer principle as the basis of his technic. His test requires thick-walled centrifuge tubes and a microdistillation system with a changeable glass distributor. In order to avoid condensation, the entire system is wrapped in four layers of wool. The apparatus is adjusted with a clamp and is heated in a paraffin bath by means of a microburner. The receiving glass is cooled with ice water. The reagents required are a 10 per cent sodium wolframate, $\frac{3}{4}$ normal sulfuric acid, a 10 per cent by volume alcoholic solution of salicyl aldehyde, 11.3 normal potassium hydroxide solution, 10 per cent by volume of sulfuric acid and 1 per cent potassium bichromate. The author hemolyzes 0.2 cc. of capillary blood with 1.4 cc. of water in a small centrifuge tube. After complete hemolysis, 0.2 cc. of wolframate is added and 0.2 cc. of $\frac{3}{4}$ normal sulfuric acid. Following each addition, the mixture is shaken carefully. After ten minutes, centrifugation is done with a high number of revolutions. The supernatant fluid is transferred to a second tube and is once more centrifugated. The entirely clear fluid is poured off immediately before the determination. In order to avoid loss of acetone, the tubes must always be closed with rubber, even during centrifugation. At the beginning of the extraction the paraffin bath is heated to 100 C.; into the receiving glass is put 2 cc. of the salicyl aldehyde solution and 2 cc. of 11.3 normal potassium hydroxide solution. Then 1 cc. of the blood centrifugate and 1 cc. of bichromate solution is put through the funnel into the distillation vessel, the cock is closed

and the receiving glass with the glass distributor is attached to the apparatus. By means of a special pipet, which is placed tightly into the neck of the funnel, 1 cc. of a 10 per cent solution of sulfuric acid is blown into the distillation vessel, while the cock is opened and the apparatus is dipped to the neck of the vessel into the paraffin bath. First oxidation is done for twelve minutes at a temperature of 100 C.; then follows distillation at 142 C. When the distillate has risen to 5 cc., it is taken from the receiving glass and under constant mixing it is put into a cooled test tube. Then the fluid is warmed for twenty minutes at 50 C. Photometry is done by inserting the green filter S 53 at a layer thickness of 10 mm. against an equally warmed compensation fluid consisting of 2 cc. of salicyl aldehyde solution, 2 cc. 11.3 normal potassium hydroxide solution and 2 cc. of distilled water. The author shows also how the total acetone and the betahydroxybutyric acid can be determined separately.

Fertility and Age of Women.—Kolb demonstrates that the natural fertility of women is reduced by different factors. As the most important ones he mentions the primary or secondary diseases and anomalies of the genital apparatus and intentional contraception. The causes for the latter are manifold, but the main reason seems to be the relatively unfavorable economic status of many couples in countries with a high civilization. In order to determine the fertility of women during the different years of their life, Kolb investigated the cases which passed through the obstetric and gynecologic clinics of the German university in Prague. The total number of cases was 59,117. He found that the limits of fertility are the twelfth and forty-ninth years. Up to the sixteenth year the fertility is comparatively slight. During the following years a great increase is noticeable. Fertility is greatest during the twenty-third year. After that the decrease is gradual. It is quite apparent after the thirtieth year, but it is especially noticeable after the fortieth year. The decrease after the thirtieth year is largely ascribable to intentional restriction of the number of children. The decrease after the fortieth year is chiefly due to a gradual decrease in the natural fertility, to the lessening of the libido and the resulting reduction in cohabitation and to various disorders, not only those of the genital sphere. By a comparison of equal numbers of births before and after the World War, a difference was noted in the fertility of the various age groups; that is, there was a relative shifting of the fertility from the younger to the older age groups. Moreover, there was a greater limitation of the natural fertility in the different age groups during the after-war period.

Ammonia Content of Cerebrospinal Fluid.—Brühl studied the ammonia content of the cerebrospinal fluid in various conditions of irritation of the brain, but particularly to determine whether the brain of spasmodic nurslings is in a state of increased irritation, also outside of the convulsive attacks. In summarizing he states that the ammonia content of the cerebrospinal fluid originates in the cerebral metabolism. Normally the ammonia content of the cerebrospinal fluid is 0 microgram per hundred cubic centimeters. In conditions of excitation the brain forms more ammonia, so that it becomes demonstrable in the cerebrospinal fluid. In those involving the brain stem the ammonia values of the cerebrospinal fluid are between 0 and 90 ± 10 micrograms per hundred cubic centimeters.

timeters, but in those involving the cerebral hemisphere the ammonia values of the cerebrospinal fluid are higher and may reach 450 micrograms per hundred cubic centimeters. Thus the ammonia values permit to a certain extent a topical diagnosis of the focus of excitation. Moreover, the ammonia content of the cerebrospinal fluid is a manometer for the degree of irritation of the centers. The author demonstrates this in clinical cases. In cases of tetany of nurslings the increase in the ammonia values indicates irritation of the cerebral centers. The amount of the ammonia indicates that in these cases the centers of the brain stem, the respiratory center and the centers of the cerebral cortex are subject to periodic excitation.

Case of Functional Branch Block During Pregnancy. I. Pines.—p. 129.
Action of Histamine on Galactose Elimination of Healthy Persons. F. Pollak and K. Bergmann.—p. 151.

Creatinuria in Progressive Muscular Dystrophy.—Netolitzky and Pichler demonstrate that in progressive muscular dystrophy the administration of aminoacetic acid causes an increase and later a decrease in the elimination of aminoacetic acid without necessarily effecting a clinical improvement. They show further that malaria therapy of progressive muscular dystrophy may be followed by a clinical improvement without there being essential changes in the elimination of creatine. Thus improvement in creatine tolerance is no measure for the functional improvement of the dystrophic musculature. Nothing definite is known about the mechanism of creatinuria, but recent investigations have disclosed that whenever creatinuria is produced experimentally the muscular glycogen is in a state of decomposition. On the other hand, all factors which cause a disappearance of the muscular glycogen result in creatinuria. From this the conclusion was drawn that creatinuria is a sign of the disappearance of glycogen from the skeletal musculature. Moreover, it appears that the connection between creatinuria and the disappearance of glycogen applies also to progressive muscular dystrophy and that the resynthesis of creatine and phosphoric acid to phosphagen is impaired. Thus the conditions might be similar to those which exist in case of poisoning with mono-iodoacetic acid. In this type of poisoning the blockage of the carbohydrate metabolism leaves no energy for the resynthesis of phosphagen and finally the phosphagen stores are entirely depleted. The authors decided to study the fate of the creatine thus liberated, hoping that this might permit conclusions in progressive muscular dystrophy. In experiments on rabbits they were able to show that creatine appears only as a result of the intoxication and they think that this suggests that creatine is eliminated because its resynthesis is made impossible by the metabolic disorder elicited by the poisoning. Thus the creatinuria would appear as the result of the impaired relation of free and combined creatine. Whether this mechanism has a part in the creatinuria of progressive muscular dystrophy is still problematic.

*Use of Mester's Test for Differential Diagnosis of Rheumatic Diseases. F. Lenocho.—p. 363.
Vitamin Therapy. R. Boller.—p. 366.

Mester's Test for Diagnosis of Rheumatic Diseases.—Lenoch performed Mester's test on 140 patients. On the flexor side of the right forearm he produced five wheals by means of the intracutaneous injection of a sterile 0.1 per cent aqueous (distilled water) solution of salicylic acid. Since for each wheal 0.2 cc. was injected, the total quantity was 1 cc. of fluid with 1 mg. of salicylic acid. The distance between the wheals was approximately 4 cm. The test was made on the fasting patient usually between 7 and 11 a. m. Patients with chronic disorders were examined while sitting down and they had to refrain from movement. Before the injections were made, blood was withdrawn from the middle finger of the right hand and

the number of leukocytes was determined. The withdrawal of the blood and the counting of the leukocytes were repeated thirty and sixty minutes after the last intracutaneous injection. The pains felt during the injections always disappeared after from one to two minutes. The wheals, which immediately after the injection had the whiteness of porcelain, gradually assumed a reddish appearance. After several hours they disappeared. In the so-called rheumatic disorders, which according to Mester include acute, subacute and chronic polyarthritis, rheumatic sciatica, spondylarthritis ankylopoietica, rheumatic heart disease, rheumatic iridocyclitis and rheumatic pains in the joints, the number of leukocytes supposedly decreases from 15 to 50 per cent, thirty or sixty minutes after the injections. The author records his experiences with the test in tables. On the basis of his observations in the 140 cases, he regards Mester's test as a valuable addition to the diagnostic methods in the so-called rheumatic diseases. As is true of the majority of the diagnostic aids, Mester's test is not infallible; but it is of assistance when it has to be decided whether an arthritis is of rheumatic or of some other origin.

Action of Prostigmine "Roche." S. Adam-Falkiewiczowa.—p. 297.
Antistreptin (Sulfanilamide) Therapy in Gonorrhea. E. Engelstein.—p. 298.

Diphtheria Bacilli in Region of Lwów.—Zopoth-Jankowska has analyzed and separated 145 different types of diphtheria bacilli in the region of Lwów. From the morphologic and biochemical point they can be divided into gravis, mitis and intermedius types and a small atypical group. The gravis type appears more frequently in diseased and convalescent patients than in healthy diphtheria carriers; the mitis type and intermedius type occur equally often in the two classes. Only one type of organism is to be found in one person whether diseased or a healthy carrier.

*Blood Transfusion in Chronic Tuberculosis of Lungs, Lymph Nodes and Serous Surfaces. Ya. O. Krizhevskiy.—p. 1472.

Blood Transfusion in Tuberculosis.—Krizhevskiy states that blood transfusions did not cause a spread in the artificially produced tuberculous focus in rabbits. Blood transfusion practiced in seventy-nine patients with various forms of pulmonary, lymph node and serous membrane tuberculosis demonstrated that, regardless of the localization and gravity of the process, the beneficial effect depended on the patient's condition. Good results were obtained only in cases in which the disease process was either stationary or at least did not exhibit a tendency to progression. Blood transfusion may be practiced because of other indications or because of trauma; extensive and progressing fibrous cavernous processes constitute the only contraindication. Blood transfusion as a therapeutic measure is indicated in tuberculous involvement of serous surfaces, in extensive lymphadenitis and in focal pulmonary tuberculosis with perifocal or pneumonic manifestations. It is contraindicated in all forms of fibrous productive and cirrhotic tuberculosis. The author considers from 200 to 300 cc. of blood the proper amount for a transfusion. The favorable time for a transfusion coincides with the phase of improvement. As a rule, one transfusion administered at the favorable moment is sufficient to bring about the desired improvement for a period of time. The transfusion may be repeated when an insufficient amount of improvement has been noted. The author did not notice a parallelism between the effect of transfusion and the presence or absence of non-specific protein reactions.

 *Form and Function of Stomach After Resection. M. P. Fedyushin.—p. 272.

Stomach After Resection.—Fedyushin reports a clinical and roentgenologic study of fifty-two patients subjected to a partial gastric resection. Roentgenologic observations were made from one and a half to two weeks after the operation and were repeated at intervals of from two months to two years. Forty-four of the patients were operated on for a malignant tumor and eight for ulcer. With the exception of one case in which total extirpation was made and of three cases in which the continuity of the gastrointestinal tract after resection was reestablished by the first Billroth operation, the operation performed was the Finsterer modification of the Reichel-Polya method in the remaining forty-eight. The author concludes on the basis of his clinical observations that even a pronounced functional alteration as demonstrated by roentgenologic studies does not preclude a clinically satisfactory result. This fact is to be accredited not so much to the advantages of any method of resection but rather to the great adaptability of the gastrointestinal tract to the new conditions. Symptoms of a "small stomach" are due to insufficient adaptation and correction of the disturbed anatomic and physiologic relations, to errors in the method of resection and to such complications as perigastritis, gastritis and jejunitis. The form of the remaining stomach shortly after the resection depends on the operative method, the inflammatory changes and the gastric tonus. With the lapse of time the form of the gastric stump alters under the influence of the pressure of its contents. The emptying of the stomach after resection is a complicated act in which hydrostatic pressure, the systole, the reflex closure of the anastomosis and the peristaltic movements of the afferent loop of the intestine are concerned. The predominant part in the emptying act is assumed in the early postoperative period by the hydrodynamic factor, while in the late period the gastric tonus and the peristaltic activity of the afferent loop of the intestine are the determining factors. The operative method determines the early form of the gastric stump and its later adaptability to the new functional demands. The technical points in the resection which influence the proper emptying are (1) the creation of a sufficiently wide anastomotic stoma, not however to exceed that of the lumen of the afferent loop of the intestine in order to prevent retrograde spilling, (2) placing of the stoma so that it occupies the lower segment of the right border of the stump after the latter's usual shift to the left, (3) avoidance of the formation of the spur in anastomosing the ends of the gastric stump and the intestine and (4) turning in of the angle of the lesser curvature into the interior of the stomach in order to avoid retrograde evacuation.

 Residual Nitrogen in Blood of Patients with Acute Rheumatism. P. I. Pliner.—p. 357.

Diagnosis of Congenital Bony Fragility.—Rabinerzon reports that a girl, aged 5 years, presented blue sclerotics and a history of eleven fractures. Roentgenograms revealed a definite osteoporosis, poorly developed bony cortical layer and evidence of healed fractures. The patient's sister at the age of 10 years had had five fractures, involving the femurs and the left radius, between the ages of 2 and 5 years. Her sclerotics were likewise blue. Roentgenograms of the upper and lower extremities showed a more or less generalized osteoporosis and signs of healed fractures of the femurs and of the left radius.

The mother, aged 33, has blue sclerotics and impaired hearing. At the age of 8 years she had three fractures. Roentgenograms demonstrated an almost universal osteoporosis. The patient's maternal grandfather, now 58 years old, suffered all his life from spontaneous fractures (about twenty-six). Of his six children three survived, and of these only one presented the syndrome of bony fragility. The grandmother was well. According to the author, osteogenesis imperfecta and osteopsathyrosis idiopathica are identical, differing only in the time of their appearance, the former belonging to the fetal period, while the latter continues through life but is particularly prone to manifest itself in early childhood. The disease presents most frequently a familial and hereditary character with no emphasis on sex. Bony fragility, blue sclerotics and otosclerosis constitute the characteristic triad of symptoms. One of these, most frequently otosclerosis, may be absent. The long tubular bones and the ribs are particularly fragile. The fractures are as a rule spontaneous and painless and they heal promptly. Charcot's theory of a lesion of the central nervous system and the theory of anomaly of the development of mesenchymal derivatives are advanced in explanation of the pathogenesis of the condition. The typical roentgenologic picture is that of osteoporosis and poorly developed cortical layer of bones. The treatment consists of a general nourishing diet and climatotherapy.

 *Spina Bifida: Prognosis and Heredity. S. Hindse-Nielsen.—p. 525.

Spina Bifida.—Three hundred and fifty-seven cases of craniorachischisis collected from Danish hospitals are analyzed by Hindse-Nielsen with particular regard to the prognosis and hereditary genesis of the condition. He was much impressed by the enormous death rate in both the operative and non-operative cases during the first half year. Of the thirty living patients who were operated on, four presented bilocular spina bifida. Several cases were reported in which there were multiple, possibly congenital, medullary foci with medullary symptoms not corresponding to the localization of the cyst, such as ataxia of the hands in a patient operated on for a lumbosacral cyst. The author's investigation does not coincide with the supposition that boys with spina bifida attain a higher age than girls. In patients not operated on, he observed the development of secondary degeneration of the spinal cord manifesting itself during puberty and probably caused by fixation of the *ectodermis medullaris* as in spina bifida occulta. Some of the patients showed improvement of rectal incontinence at the ages of 7, 19 and 40 years. In two patients a spontaneous rupture of the cyst took place at the ages of 14 and 19 years, respectively. Three women bore five normal children. As the death rate during the first year of life is so much greater among patients who have not been operated on than those who have, and as the present investigation confirms the fact that of the patients operated on only those with meningocele have a chance of attaining good health, the author suggests (1) that as a rule only patients with true meningocele or with myelocele accompanied by minor symptoms should be operated on, (2) that patients with syringomyelocele should be left alone and (3) that children with spina bifida should be transferred to neurosurgical departments. Certain conditions indicate that the delay in the closure of the neural tube, which can be assumed to be the origin of the medullary cyst, takes place before the third fetal week. The analysis of this series does not solve the problems of the possible exogenous causes of the malformation. Through personal investigation of 124 families, the author has found additional cases of craniorachischisis besides the hospital cases making up the series. The greatest number of the deformity observed in the same family and distributed among three groups of sisters and brothers was seven. The author had confirmed the existence of fifty additional cases of spina bifida among 12,550 persons belonging to 124 families. This fact points to a considerable familial concentration and the possibility of a hereditary factor in the genesis of the condition.

METABOLIC STUDIES ON PATIENTS WITH GOUT

JOHN H. TALBOTT, M.D.
AND
FREDERICK S. COOMBS, M.D.
BOSTON

The cause of gout is unknown, although most data concerning the pathogenesis indicate that it is a metabolic dyscrasia rather than an infectious or a deficiency disease. In affirming that gout is a metabolic dyscrasia we choose to employ a liberal interpretation of this term and imply a disturbance of function, be it chemical, physical or hormonal. Investigations of the chemical changes associated with acute and with chronic gout have been concerned principally with the variation in concentration of uric acid in the blood and in other body fluids. At present it is accepted that gouty arthritis is accompanied by an increased concentration of uric acid in the blood. Agreement is lacking, however, concerning the mechanism of this increase and the fate of this substance in body economy.

Data were presented from this laboratory in 1935¹ which indicated that gout is accompanied by changes in the body more widespread than seemingly could be accounted for by a dysfunction in the excretion or formation of uric acid. These data were derived from a study of the water and electrolyte exchange in two patients during recurrent attacks of gouty arthritis. One patient had no articular deformity at the time this study was made. The other patient had mild deformities of the joints of the hands and the feet. Since this earlier report, observations have been made on patients without demonstrable evidence of chronic gouty arthritis as well as on patients with deforming articular involvement. The distinction between acute and chronic gout is believed to be relative, and we agree with Kinglake² that: "The terms signify different degrees of the same affection. They imply no sort of distinction in the quality of the disease, but merely in its quantity or force."

SUBJECTS

In this report data from twenty-four patients (table 1) with acute or chronic gout as well as data from

control subjects will be discussed. Twenty-two of the gouty patients were males and two were females. The two women, K. He. and M. Tr., had, in addition to the usual manifestations of the disease,³ subcutaneous tophi, from which urate crystals were removed. Each male patient had had two or more attacks of acute arthritis, and on two or more occasions the concentration of uric acid in the serum was greater than 6 mg. per hundred cubic centimeters. Osseous tophi were suspected from the roentgenograms in nineteen of the males. Thirteen had soft tissue tophi containing urate crystals. All the patients seen during an acute attack responded to full doses of colchicine. The seven patients who acted as controls were suffering, respectively, from the following conditions: myxedema, diabetes insipidus, diabetes mellitus, rheumatoid arthritis, undernutrition and urate lithiasis.

METHODS

The metabolic data were collected while the patients were hospitalized in the metabolism ward of the Massachusetts General Hospital. Approximately the same number of hours of sleep were obtained at night by each patient. During the day they were ambulatory if asymptomatic, although physical activity was restricted. The daily fluid intake was selected as follows: Each patient chose an amount of fluid suitable for extra-dietary consumption. When the selection had been made, the fluid intake was constant in the periods of freedom from acute articular symptoms.

All the patients with gout were observed for a minimum of three days on a low purine diet and twelve for three or more weeks. Although medication was required for control of symptoms, all twenty-four patients were observed for at least three days on a low purine diet without medication. When no mention is made to the contrary, it may be assumed that the patient consumed a constant amount of fluid and food each day and that no medicine was administered.

The methods for analysis of the chemical constituents of the blood and urine have been described previously.¹ The procedure for determining the insensible loss of weight was similar to that described by Benedict and Root.⁴ A silk scale accurate to 10 Gm. was used for measurement of body weight. An especially constructed stretcher was used when the patients were not ambulatory. At night, before going to sleep, the patient voided and was weighed. The following morning, approximately nine hours later and before the patient voided, a second weight was obtained. All the data on insensible loss of weight were collected in the late winter and early spring. The meteorologic observations,

This investigation was aided by the Corn Industries Research Foundation and the Josiah Macy Jr. Foundation.

barometric pressure, relative humidity and external temperature were obtained from the Weather Bureau, United States Department of Agriculture, Boston.

ANALYSIS OF RESULTS

The data to be presented may be divided conveniently into three parts: (1) The fate of uric acid in gouty patients with and without demonstrable evidence of damage to the kidneys, (2) cyclic changes in the metabolic processes of the body during arthritis-free periods as well as during acute attacks and (3) the treatment of acute and chronic gout.

The Fate of Uric Acid in the Body.—Although it has long been known that gout is accompanied by an increased concentration of uric acid in the blood, the mechanism of this increase has not been established. Since uric acid is an organic substance normally present in the body, it is conceivable that one of three processes or a combination of them might be responsible

matoid arthritis was 28 mg. per hundred cubic centimeters, and for the patient with urate calculi it was 48 mg. These observations correspond to those of Grafe⁶ and Loewenhardt⁷ for nongouty subjects.

Similar studies on patients with gout showed certain contrasts. It may be noted in table 2 that eight patients were able to concentrate uric acid in the urine in an amount greater than 75 mg. per hundred cubic centimeters. All but one of these was less than 50 years of age, and all except this patient excreted more than 25 per cent of phenolsulfonphthalein in the first fifteen minutes after intravenous injection of 0.6 mg.⁸ For none of the eight was the specific gravity of the urine fixed below 1.014, and none showed a diastolic blood pressure greater than 98 mm. of mercury. It is believed these patients with gout had no renal insufficiency and that their kidneys, therefore, were able to excrete water and solids and to concentrate uric acid. Two of the patients were studied for long periods, with results

for this increase. These are (a) diminished excretion, (b) diminished destruction and (c) increased formation.

In the gouty patient past the age of 50 with clinical evidence of renal insufficiency,⁵ the increased concentration of uric acid, it is believed, may be a function of poor elimination. However, prolonged observation of patients without demonstrable renal disease who are on a low purine regimen does not justify the general application of this assumption.

Before we present data concerning the gouty patients, observations on two controls will be discussed. The first subject had rheumatoid arthritis with moderate involvement of the joints as judged from the physical examination and roentgen studies. The second had renal lithiasis, and, although he had passed several urate calculi, it was not believed that he was suffering from gout. Both were observed on a low purine diet for nine days. Both had normally functioning kidneys, judging from the medical history and the clinical tests for renal function. The concentration of nonprotein nitrogen and of uric acid in the serum were normal in each patient at two determinations. The maximum daily concentration of uric acid in the urine for the patient with rheu-

matoid arthritis was 28 mg. per hundred cubic centimeters, and for the patient with urate calculi it was 48 mg. These observations correspond to those of Grafe⁶ and Loewenhardt⁷ for nongouty subjects. Similar studies on patients with gout showed certain contrasts. It may be noted in table 2 that eight patients were able to concentrate uric acid in the urine in an amount greater than 75 mg. per hundred cubic centimeters. All but one of these was less than 50 years of age, and all except this patient excreted more than 25 per cent of phenolsulfonphthalein in the first fifteen minutes after intravenous injection of 0.6 mg.⁸ For none of the eight was the specific gravity of the urine fixed below 1.014, and none showed a diastolic blood pressure greater than 98 mm. of mercury. It is believed these patients with gout had no renal insufficiency and that their kidneys, therefore, were able to excrete water and solids and to concentrate uric acid. Two of the patients were studied for long periods, with results

fixed at 1.012 or less, and in a similar number the diastolic blood pressure was greater than 98 mm. The excretion of uric acid associated with a low purine diet was not determined for four patients, and in table 2 only studies of renal function are given for these patients.

No evidence was obtained in these studies which pertained to the hypothesis of Brugsch⁹ that gouty patients show a diminished destruction of uric acid in the body. In refutation of this assumption, however, the data of Folin¹⁰ should be mentioned. In three patients with gout he noted that the injection of uric acid was followed by as rapid a disappearance of the substance as in normal controls. Uricolytic enzymes are not distributed generally throughout the body,¹¹ and we believe that the fate of most of the uric acid in the blood and other body fluids is either excretion or deposition.

The third hypothesis for the elevation of the uric acid content in the blood of gouty patients, i. e., increased formation, seems to us to be the most acceptable. The concentration of uric acid in the serum was 10 mg. per hundred cubic centimeters or greater in eight of the twenty-four patients. Five of the eight were less than 40 years of age, had normally functioning kidneys and were able to concentrate uric acid in the urine in an amount greater than 50 mg. Both F. Mc. and F. Na., neither of whom showed renal insufficiency, excreted more than 2 Gm. of uric acid daily while on a low-purine diet in attack-free periods. On a similar diet two control patients without gout excreted less than 1 Gm. daily. It is thus apparent from our data that in the first years after the onset of articular symptoms gouty patients show no constitutional inferiority of the kidneys in regard to the excretion of uric acid. We believe further that any inferiority which may be demonstrated later is related to renal damage which is secondary to the prolonged and excessive excretion of uric acid.

The formation of urate calculi in gouty and non-gouty¹² patients should be mentioned in this section. Urate stones sufficiently large to produce colic were passed by four of the patients with gout; in two, renal colic preceded symptoms of arthritis. On the other hand, six patients referred to us by Dr. Fuller Albright were examined for gout because they had passed urate calculi. A history of articular disturbance was investigated, the concentration of serum uric acid was determined and roentgenograms were taken of the hands and the feet. No additional evidence was obtained in any of these cases which suggested a diagnosis of gout. We conclude, therefore, that urate calculi may accompany the prolonged and excessive excretion of urates in patients with gout but that the passage of a urate stone does not imply a presumptive diagnosis of gout.

Cyclic Changes in Metabolic Processes.—An alteration in the concentration of certain constituents of the body fluids during an acute attack of gout has been known for many years. His,¹³ Fletcher¹⁴ and others

observed a diminished urinary excretion of urate before the onset of acute symptoms, this being followed in a few days by an increased excretion. With patients on a low purine diet, this observation was not only confirmed by us but was extended to include other constituents of the body fluids and other functions of the body.

A frequent observation while patients were consuming a constant amount of food and fluid was a diuresis which immediately preceded an acute attack of gout.¹ This diuresis began from twenty-four to seventy-two hours before the onset of articular symptoms and the elevation of body temperature. It was accompanied by an increased excretion as well as an increased concentration of various urinary constituents but especially of sodium and chloride (fig. 1). The maximum output of fluid was noted immediately before or on the day of maximum articular distress and was approximately twice the daily output observed prior to the diuresis.

* Percentage of dye excreted in first fifteen minutes after injection.

† Maximum specific gravity in four hourly collections following abstinence from food and fluid for eleven hours. Only significant figures are given.

‡ A scale of + to ++++ is employed.

On the day of the maximum diuresis an increased excretion of urate was observed, which undoubtedly corresponded with the increased output noted by His and by Fletcher. The increased excretion of water and salt subsided presently and was followed by a diminished excretion. These fluctuations in excretion tended to recur in patients having frequent attacks of acute gout, and it seemed appropriate to apply the term gout cycle to describe them.

It was observed further that in the prodromal period before the onset of acute gout a gain in body weight accompanied the diuresis. It was assumed that with a constant regimen only a significant diminution in insensible loss could explain this paradoxical phenomenon.¹ Study of the precise changes in insensible loss during the prodromal period has confirmed this assumption. These changes were illustrated in two acute cycles in patient F. Mc. (fig. 2). During the three days beginning February 3, the diuresis plus the gain in body weight was about 1,600 Gm. At the same time the decrease in insensible loss of weight was more than 1,700 Gm. Again, during the two day period before February 10 the diuresis plus the gain in weight was

approximately 1,900 Gm., while the diminution in insensible loss was about 1,800 Gm. That as great a cyclic change in insensible loss is not a physiologic function common to many patients may be deduced from our failure to observe similar changes in several controls. During the period of observation just mentioned, a patient with urate lithiasis without gout showed a mini-

Fig. 1 (case 17).—Increased excretion of water and chloride during two acute attacks of gout in patient of 21.

mal variation in daily output of fluid and minimal changes in daily insensible loss.

In a six week period of observation on patient F. Na.,¹⁵ simultaneous determinations of insensible loss of weight were made on three control patients studied consecutively. During fourteen days of observation of a patient with diabetes insipidus, the maximum variation in insensible loss was 10 Gm. an hour. At the same time the cyclic variation in F. Na. was about 40 Gm. an hour. The control patient was then replaced for an eight day period by a patient with myxedema and later for an eleven day period by a patient with rheumatoid arthritis. The maximum daily variation in insensible loss by these two control patients was 11 Gm. an hour. The maximum variation in F. Na. during these periods was 37 and 31 Gm. an hour, respectively. In F. Mc. the diminution in insensible loss during both cycles was followed by acute arthritis; in F. Na. two of the three cycles were accompanied by acute symptoms.

The term gout cycle as originally employed included only the rhythmic changes which accompany the acute articular symptoms, as at that time no studies had been made of prolonged periods between attacks. Continued study of patients with gout has caused us to alter our former deductions. It is now believed that cyclic changes in the internal environment of the body similar to those observed during acute articular gout may occur also during symptom-free periods, and in all patients with gout whom we have studied the disease has been a continually recurring phenomenon irrespective of the presence or the severity of acute symptoms.

The cyclic variation in insensible loss, urinary volume and body weight has been studied in seven patients during twenty-four periods of from five to eight days each. In fourteen cycles acute gouty arthritis followed the decrease in insensible loss; in ten this decrease occurred without an exacerbation of articular symptoms. The majority of the symptom-free cycles, however,

were not associated with as great a variation in metabolic changes as were the cycles with acute gout. It seemed impossible, however, to predict whether or not a decrease in insensible loss during any one cycle would be followed by acute arthritis. This is illustrated in figure 3, in which two cycles are shown graphically for patient J. Co. From April 10 to 13, 1936, the diminution in insensible loss exceeded 70 Gm. an hour. After this decrease, a second maximum was reached on April 16. The first diminution in insensible loss was followed by an acute attack, while the second was not.

In the search for an explanation of this continuous cycle variation, which occurred with and without acute articular symptoms, a possible relation to meteorologic changes was considered. In this aspect of the study, barometric pressure, relative humidity and atmospheric temperature, observed at 8 o'clock each morning, were compared with daily changes in insensible loss and urinary volume. When most of these observations had been charted, a consistent correlation was noted between changes in barometric pressure, insensible loss of weight and diuresis. In the symptom-free periods a fall in barometric pressure preceded the diuresis by approximately twelve hours. In cycles with acute symptoms the maximum fall in barometric pressure preceded the diuresis and the articular symptoms by from twelve to twenty-four hours. Figure 3 shows that the diminution in barometric pressure and the insensible loss occurred at approximately the same time. There was chronologic agreement in eleven of the fourteen attack cycles and in all the symptom-free cycles. The fluctuations in external temperature and relative

Fig. 2 (case 17).—Changes in urinary volume, body weight and insensible perspiration during two attacks of acute gout in patient of 21.

humidity were greater and more variable than those in barometric pressure, and no obvious relationship was noted between these observations and the gout cycle. It is possible that a subtle correlation between these variables exists, but it was not evident from our studies.

This quantitative study has given us new information about the patient with gout and laboratory evidence

15. Ludwig, A. O.; Bennett, G. A., and Bauer, Walter: A Rare Manifestation of Gout; Widespread Ankylosis Stimulating Rheumatoid Arthritis. *Ann. Int. Med.* 11: 1248 (Jan.) 1938.

in support of certain clinical observations. There are patients with gout who believe that they can predict an acute attack of arthritis from an increased urinary output,¹⁶ gastrointestinal distress,¹⁷ suppression of sweating or gain in body weight. Although it is not common for the patient with gout to forecast a storm from symptomatic changes in his joints, as the patient with rheumatoid arthritis frequently does, an observation published in 1816 by Scudamore¹⁸ partially refutes this statement: "I know several gouty patients, whose sensibility to the immediate influence of the east wind . . . is almost inevitable." It is recognized that an east wind generally accompanies a falling barometric pressure, and the association of meteorologic changes and symptoms of gout may be greater than is now appreciated.

In summary, we have stressed the occurrence of cyclic changes in certain metabolic functions of patients with gout. These changes have been observed in periods with and without symptoms of acute arthritis. In several control patients without gout, the magnitude of the change of these variables was significantly less.

Treatment.—During the periods of study and the collection of the foregoing metabolic data, certain observations were made concerning treatment. It is our belief that there is no known cure for gout and that once the diagnosis is confirmed the disease will persist until the patient dies. On the other hand, much may be done to afford symptomatic relief, especially during acute attacks, when rest in bed, abundant fluids and a soft diet are indicated. Probably the most important drug to give is colchicine. In the crystalline form¹⁹ this preparation is more reliable than the wine or tincture of colchicum, the potency of which may vary. For acute symptoms colchicine may be prescribed in amounts of $\frac{1}{120}$ grain (0.0005 Gm.), to be taken every one or two hours until eight, twelve or even sixteen doses have been ingested. The symptoms of adequacy are associated with the development of nausea, vomiting or diarrhea. Many patients learn from practice the optimum number of pills to take and thereby obtain the desired alleviation of articular pain without the undesirable intestinal symptoms.

The mechanism of the action of colchicine is not known. Few pharmacologic studies have been made, and we can say little more than that it is effective clinically. It has been given by us repeatedly to patients having frequent attacks, and we have not observed any untoward symptoms or signs other than those just discussed. We have not observed a patient to be hypersensitive to this drug, nor does the drug appear to lose its efficacy with repeated ingestion.

The treatment of gout during arthritis-free periods has been and continues to be a subject for argument. Innumerable regimens and diets have been proposed, the merits of which are difficult to evaluate. There is no index of therapeutic efficiency comparable to the alleviation of pain during acute attacks, and it is our belief that the number and duration of attacks a year is the best index of the worth of any regimen. Within limits we believe that deposition of sodium urate is greater and the osseous involvement more extensive

with frequent and prolonged attacks than with infrequent attacks of short duration.

The protein content of the diet and the alcoholic content of fluids have been the battleground for most discussions of the treatment of the chronic form.²⁰ Most clinicians favor the exclusion from the diet of foods with a high purine content, a practice with which we are in agreement. We believe that the benefits of a low protein and a scrupulously low purine diet, however, have been exaggerated. Evidence supporting our belief was obtained from patients F. Na. and F. Mc. In three periods, totaling more than 7 months, F. Na. was observed in the metabolism ward on a low purine diet. During this time he had twelve attacks of acute arthritis and had severe gout on twenty-seven days. In the following eight months, at home, in

Fig. 3 (case 9).—Changes in barometric pressure and insensible perspiration during two cycles in patient of 78.

which he was on a diet of his own selection, without restriction of purine, he had seven acute attacks and had severe gout on eighteen days. Colchicine taken during the acute attacks was the only medicine taken regularly during both periods.

Similar data were obtained from F. Mc. During a nine month period in the hospital on a low purine diet he had twenty-one attacks of acute arthritis and spent thirty-nine days in bed with severe gout. In the fourteen months after discharge he had seven acute attacks and spent only seven days in bed. In this period, at home, he had red meat at least once a day and enjoyed a moderate intake of beer and occasionally hard liquor. In the hospital he was given no medicine regularly except colchicine for acute symptoms. At home he took colchicine for acute symptoms, and, in addition, from 40 to 60 grains (2.4 to 4 Gm.) of acetylsalicylic acid daily. At the end of the second period he began a third, which lasted twenty-six months. In this period he took, in addition to acetylsalicylic acid, $\frac{3}{120}$ grain (0.0015 Gm.) of colchicine daily. During this time he had seven acute attacks of gout

19. In the United States colchicine may be obtained from Abbott Laboratories, Merck & Co., and Parke, Davis & Co.

20. Brogsitter, A. M.: *Diät für Gichtkranke*, ed. 3, Stuttgart, 1937.

and spent eight days in bed. Clinically there appeared to be no greater progression of the articular changes while he was receiving a liberal purine intake than when he was in the hospital on a low purine diet. It is of interest that during the four year period of observation the number of attacks a year and of days spent in bed during the low purine regimen was about tenfold that observed while the patient was eating a liberal portion of meat each day.

The experience of J. Co. may be cited, although we have no control observations for comparison. This patient is now 79 years of age and has had articular symptoms for more than forty years. During this time he has been a bartender and has consumed a liberal amount of alcoholic beverages as well as of red meat each day. For the past fifteen years he has had one or two mild attacks of acute arthritis annually. He has large aural tophi but has no crippling deformity of his extremities. If a diagnosis of gout had been made after the onset of his symptoms and he had been placed on a low purine diet, it is not unreasonable to believe that undue credit would have been given to the diet.

The efficacy of the prolonged use of acetylsalicylic acid, colchicine or cinchophen (and its derivatives) between acute attacks is uncertain. Acetylsalicylic acid is frequently desirable for mild aches and pains and may be used as in the treatment of other types of arthritis. Hench,²¹ Thannhauser,¹¹ Pratt,²² Volini,²³ Herrick²⁴ and others have stated the conviction that benefits are derived from the use of cinchophen. In our series we have used cinchophen infrequently because we believe that the danger from poisoning outweighs the benefits from its use. The administration of small amounts of colchicine each week during attack-free periods has been advocated by Cohen,²⁵ and our data are in agreement with this practice. Many of the patients in our series who have more than two attacks of gout a year are given $\frac{3}{120}$ grain (0.0015 Gm.) of colchicine each day for two or three days each week. The use of colchicine in this amount in several cases for more than two years has not produced any recognized toxic symptoms, and we believe that it is a safe practice.

A liberal fluid intake is important, as well as a reducing diet for those who are overweight.²² A diet adequate in minerals and vitamins would appear obvious, although there is no convincing evidence that massive doses of either minerals or vitamins have any particular merit.

SUMMARY AND CONCLUSIONS

Twenty-four patients with gout were studied.

The increased concentration of uric acid in the blood is believed to be a function of increased formation rather than of diminished excretion or of destruction.

The term gout cycle was used to describe a cyclic variation in water and salt exchange observed during arthritis-free periods and during acute attacks. Accompanying the increased excretion of water and salt, there was a gain in body weight and a diminution in insensible loss of weight. The changing metabolic functions appeared to be associated with changes in barometric pressure.

In the treatment of acute gouty arthritis, the use of crystalline colchicine has been very satisfactory. In asymptomatic periods, the prolonged use of a low purine and a low protein diet seems to possess no particular merit. It is our belief that a diet adequate in protein, carbohydrate, fat, vitamins, minerals and fluids should be prescribed for most patients with gout.

ROLE OF CARBON MONOXIDE IN THE CAUSATION OF MYOCARDIAL DISEASE

HARVEY G. BECK, M.D.

AND

GEORGE M. SUTER, M.D.

BALTIMORE

In the course of study of a large group of patients whose illness could unquestionably be attributed to frequent and prolonged exposure to carbon monoxide gas, we were forcibly impressed with the frequency with which cardiac symptoms appeared. In most instances these symptoms were chiefly functional. However, in some cases the clinical manifestations were predominantly those of organic heart disease.

Carbon monoxide chemically considered is nontoxic; that is, it has no direct effect on the tissues of the body. Its injurious action is due indirectly to its extraordinary affinity for hemoglobin, because of which the oxygen of the oxyhemoglobin molecule is replaced by carbon monoxide, thus producing a state of anoxemia. In consequence of this anoxemia, functional disturbances arise. These are due primarily to mere oxygen want and secondarily to the anoxic lesions produced through oxygen deprivation.

Structures endowed with a rich blood supply, such as the myocardium and the central nervous system, normally utilize more oxygen than those less abundantly supplied; consequently, in states of anoxemia the damage to tissue in these organs is relatively more pronounced.

Carbon monoxide anoxemia does not differ essentially from anoxemia associated with severe forms of anemia. The factor responsible in both instances is the diminished oxygen-carrying capacity of the hemoglobin.

In recent years much evidence has accumulated showing a definite relationship between anoxemia and cardiovascular disease, as witnessed clinically and at autopsy, in cases of carbon monoxide poisoning and in experiments with animals exposed to carbon monoxide.

Attention has been directed to the association of angina pectoris and pernicious anemia, the former being attributed to the anoxemia produced by the latter. Keefer and Resnik¹ stated the opinion that anoxemia is a constant factor in angina pectoris and that it is possible to demonstrate anoxemia in all cases. Elliott,² who reported a case of angina pectoris with severe anemia in the presence of healthy coronary arteries and aorta, expressed the belief that the occurrence is more than a coincidence. His observations are in accord with those of Cabot,³ who reported three cases

in which intense and typical angina was associated with pernicious anemia without changes in the coronary arteries. That angina pectoris may occur without associated coronary disease has also been affirmed by Allbutt,⁴ who cited fifteen cases in which the coronary vessels appeared normal at autopsy. He expressed the opinion that the anginal syndrome occurring in association with coronary or aortic disease is produced by anoxemia of the myocardium.

PATHOLOGIC PHYSIOLOGY

Campbell⁵ observed in physiologic experiments with carbon monoxide on tissue oxygen tension a striking resemblance to the effects of hemolysis, bleeding and breathing oxygen at very low pressure. The effects on animals of prolonged exposure to carbon monoxide were an increase in hemoglobin and an increase in the number of red cells per cubic millimeter of blood. These results are similar to those recorded by Nasmyth and Graham⁶ in 1906. With the gradual increase of the red cells there was a corresponding increase in the amount of carbon monoxide the animals could tolerate.

By exposing animals (rabbits, guinea pigs, rats and mice) to a relatively low percentage of carbon monoxide (0.065 per cent) and then gradually increasing the concentration, a considerable degree of tolerance, similar to that produced by low oxygen pressure in inspired air, was established. Campbell's experiments proved that the heart muscle does not tolerate a low oxygen tension and that as a result circulatory failure develops, with congestion, edema, degeneration and atrophy. The greatest changes from congestion occurred in the liver, lungs, heart muscle and brain.

The pathologic changes caused by carbon monoxide poisoning affect primarily the vascular system (Litzner⁷). There are marked dilatation of the peripheral vessels, slowing of the blood stream, increased permeability of the vessel walls with hemorrhage, perivascular infiltration and edema. Chornyak and Sayers⁸ observed in dogs asphyxiated with carbon monoxide small petechial hemorrhages, most of them not larger than would be caused by diapedesis through the dilated vessels. These small punctiform hemorrhages are characteristic lesions and may occur in any organ in the body. Larger hemorrhages also occur. Fatal cases of epistaxis and hemoptysis have been reported, and cases of bleeding from the stomach, intestine and kidneys have been observed clinically. In consequence of the vascular changes incurred through impaired nutrition, arterial spasm, thrombosis and gangrene may develop. Kroetz⁹ stated that the classic anoxic lesions in the heart of victims of carbon monoxide are hemorrhage, necrosis and processes of granulation and regeneration and that their coexistence with similar lesions in the brain adds to their significance. The lesions undergo rapid regenerative changes, and the processes of repair may be fully developed by the ninth day. He inferred that the condition may be in the nature of toxic myocarditis with symptoms of cardiac

dilatation, lowering of blood pressure and alteration in the cardiac sounds, rate and rhythm. Patients with mild involvement often recover promptly, as is indicated by the clinical course and electrocardiographic studies. Patients with severe involvement ultimately die a cardiac death.

The lesions affecting the heart have certain well defined areas of predilection. These are in the papillary muscles of the mitral valves and in the wall of the left ventricle. In nine patients examined post mortem by Gey,¹⁰ definite macroscopic hemorrhages were observed in the apex of the papillary muscles of the mitral valve, and he expressed the opinion that such hemorrhages account for the dilatation of the left ventricle usually observed at autopsy. The acute dilatation he attributed to atony of the heart muscle. When the dilatation persists over a longer period it implies damage to the heart muscle through hemorrhage and necrosis. The nutritional changes resulting from these lesions not only affect the heart muscle but may affect the bundle of His, as has been demonstrated by Lewis, White and Meakins,¹¹ who observed auriculoventricular block in cats poisoned by carbon monoxide. Greene and Gilbert¹² by oxygen deprivation produced in man diminished conductivity of the auriculoventricular nodes as well as of the bundle of His. Haggard¹³ was able to demonstrate in dogs auriculoventricular dissociation and even complete block, but the latter did not occur until increased anoxemia developed through respiratory failure. By stimulating respiration and promoting elimination of carbon monoxide by inhalation of carbon dioxide and oxygen, conduction was restored to normal.

Colvin¹⁴ observed a chauffeur poisoned by automobile exhaust gas who at the onset had pulsus alternans, with a rate of 140 a minute. Twenty-six hours later he had sinus arrhythmia and intraventricular block. Two days later the left branch of the bundle of His was involved. In five days the condition had entirely cleared. When the injury to the myocardium persists over a long time it causes a permanent disability (Holm¹⁵).

In patients with carbon monoxide anoxemia, thrombi commonly occur in the small vessels; larger vessels are not exempt, however, as many cases of coronary thrombosis have been reported. Nagel¹⁶ reported two cases of coronary disease from carbon monoxide gas and cited eight cases reported by Kroetz. Wachholz¹⁷ observed changes in the myocardium, with a fall in blood pressure, stasis, thrombus formation and occlusion of a branch of the coronary artery. The pathologic changes observed by Kaufmann¹⁸ in a man aged 35 who died from an embolism in a healthy left coronary artery were dilatation of the left ventricle and pulmonary edema. Zondek¹⁹ by means of roentgen examination, visualized cardiac dilatation in rabbits

acutely poisoned by carbon monoxide. In cases of acute poisoning by coal gas the heart may rupture. Pulvertaft²⁰ reported the case of a girl of 19 who committed suicide by putting her head in a gas oven. Although the right ventricle had ruptured, microscopic sections revealed a normal heart and coronary vessels.

Investigation on the pathogenesis of angina pectoris by Christ²¹ showed that it results as a rule from acute coronary insufficiency and that, as a feature of the disease, disseminated ischemic necrosis not infrequently develops. Similar necrotic changes have been produced experimentally in animals by Büchner.²² Even mild exposure to carbon monoxide caused such lesions in rabbits. In both man and animals Dietrich and Schwiegl²³ caused acute coronary insufficiency through deprivation of oxygen.

On the basis of these observations and numerous others not mentioned, we feel convinced that carbon monoxide has an important etiologic role in the development of myocardial lesions after asphyxiation with carbon monoxide in patients with no history of preexisting heart disease.

REPORT OF CASES

Our personal observations are based on the study of a series of 136 cases of chronic carbon monoxide anoxemia extending over a period of fifteen years. The symptomatic manifestations and clinical syndromes have been described in previous publications.²⁴ The chief complaints of many of the patients were referable to the cardiovascular system. The most outstanding symptoms were palpitation, dyspnea, irregular heart action and precordial distress. The following cases, selected from this group, serve to emphasize the importance of carbon monoxide as an etiologic factor:

CASE 1.—G. D., a farmer and cattle dealer of West Virginia, aged 36, referred by Dr. Jones and Dr. Woodyard, presented a history of coronary thrombosis, heart block and symptoms of chronic encephalitis, with the parkinsonian syndrome.

The mother had died of angina pectoris and the father of paralysis agitans. The patient's past history was not significant. His health had been good until February 1935, when an attack diagnosed as influenza suddenly developed and he had a temperature from 103 to 104 F. He was admitted to the hospital, where a diagnosis of coronary thrombosis was made. After six weeks he returned home. In June, after extraction of his teeth, he had heart block, with a pulse rate of 30 a minute and typical attacks of the Adams-Stokes syndrome. He slowly recovered from these attacks but continued to be extremely nervous, emotional and obsessed with fear. On admission to the clinic Sept. 25, 1935, he was highly emotional and introspective, exhibiting intense fear when alone. He was considerably overweight and presented the typical parkinsonian syndrome, with masklike expression, flushed face, dry and desquamating skin, tense and rigid muscles and inability to feed himself, sit erect or stand and walk unaided. His speech was slow, hesitating and monotonous, and he had difficulty in finding words to express himself. The blood pressure was 132 systolic and 92 diastolic. The cardiac measurements were normal. There were an occasional extrasystole and a soft systolic murmur at the base. There were no changes in the breast sounds. The abdominal reflexes were absent, the plantar

reflexes were normal and the deep tendon reflexes were hyperactive. There were coarse tremor of the tongue and definite intention tremor of both hands. The neurologic diagnosis, which was confirmed by Dr. Gillis, was chronic encephalitis, probably the result of carbon monoxide anoxemia.

Dr. King, who saw the patient later in consultation, stated that his heart was normal on physical examination except for extrasystoles, and the only abnormality found in the electrocardiogram was extrasystoles. Laboratory studies showed an occasional trace of sugar in the urine, a normal amount of blood sugar and of blood cholesterol and a negative Wassermann reaction. When the patient was admitted, the hemoglobin content was 100 per cent, a blood count showed 5,620,000 red cells and 13,950 white cells and the differential count was normal. The basal metabolic rate was minus 8.6 per cent.

The patient lived in the midst of a newly developed oil and gas field. The home was heated by burning unrefined wet gas from the patient's own well, both day and night, in open unventilated gas heaters. During his illness gas was escaping from an imperfect heater in his bedroom. His wife noticed the odor of gas, and the doctor, recognizing it, ordered the windows open for protection. During this period the patient was stuporous, delirious, gasping for breath and nauseated; he vomited and broke out in a cold perspiration. His wife, who occupied the same room, became ill and suffered from nervousness, dizziness and headache, and his sister, who slept in an adjoining room, was similarly affected. The patient made a remarkable recovery when he was freed from exposure to gas. The cerebral as well as the cardiac symptoms completely subsided.

CASE 2.—W. A. M., a physician, aged 74, presented himself for examination in December 1935 with a diagnosis of angina pectoris and cerebral thrombosis and a history of coronary thrombosis fourteen years before.

In the winter of 1921 he suffered an attack of severe precordial pain, in which he fell and was unconscious. This pain persisted for two weeks and required the use of morphine for five days. A diagnosis of coronary thrombosis was made. The patient recovered slowly. He remained free from cardiac symptoms until October 1935, when he began to complain of paroxysmal precordial pain of two or three hours' duration, but he was able to continue his work. He also complained of dyspnea and cough. For his precordial attacks he resorted to the use of vasodilators, which afforded relief.

He gave a history of having been exposed to carbon monoxide for a period of thirty years, during which he frequently experienced the symptoms characteristic of anoxemia. He spent on an average seven hours daily in his office, which was heated by gas stoves. In cold weather the gas burned day and night.

In March 1935 an acute attack of "influenza" developed and he was confined to bed for three weeks. This was followed by symptoms suggesting a mild form of cerebral thrombosis, with slight weakness and paresthesia in the left arm and left leg and a staggering gait. These symptoms slowly subsided.

Examination Dec. 3, 1935, showed moderate arteriosclerosis, a normal-sized heart and an occasional extrasystole but no murmur; the blood pressure was 102 systolic and 62 diastolic, the pulse rate 70 and the temperature subnormal; moist rales were heard in both bases. Urinalysis, a blood count and a Wassermann test gave negative results.

It is significant that during the summer months of 1935 he had no attacks of angina pectoris, while during the following winter months he had frequent attacks. In the fall, when he began burning gas in his office, the attacks returned, averaging about one daily until November 11, when he motored to Florida. On this trip he had only one attack, which occurred several hours after he left his home in Clarksburg; but on his return two weeks later they recurred. However, since December 1936, when the fuel for heating his office was changed from gas to coal, he has been absolutely free from attacks.

COMMENT

These two patients suffered not only from the effects of carbon monoxide anoxemia on the heart but from its effect on the central nervous system. In case 1

there were typical symptoms of encephalitis, with the parkinsonian syndrome, and in case 2, symptoms of cerebral thrombosis. Anoxic lesions are found more frequently in the brain than in the heart, but they may occur in the two organs in the same patient, as in the cases cited; Liebmann²⁵ reported the case of a woman who died of poisoning by illuminating gas in whom the autopsy revealed multiple cerebral hemorrhages and severe interstitial and parenchymatous myocarditis in the wall of the left ventricle. The cerebral symptoms when pronounced may so completely overshadow the cardiovascular symptoms as to make the diagnosis difficult.

The electrocardiographic studies in case 1 may seem to have been disappointing, as they failed to show any abnormality after the clinical manifestations of both coronary thrombosis and heart block had disappeared. Records show that, in most instances of asphyxiation with carbon monoxide followed by coronary thrombosis, the electrocardiogram becomes normal as soon as the process subsides; and Haggard succeeded in restoring cardiac conduction to normal in dogs after the development of block associated with severe anoxemia.

In case 1 the red cell count of 5,620,000 was significant. A count of 5,000,000 or over occurred in 45 per cent of our cases in which the count was tabulated. Particularly noteworthy in case 1 is the history of angina pectoris in the mother and paralysis agitans in the father, two diseases not infrequently encountered in association with chronic carbon monoxide poisoning. The father and mother lived in the same community as the patient and under similar circumstances; they burned natural gas in open unvented heaters for twenty years.

CASE 3.—B. C. K., a lawyer aged 59, a resident of Oklahoma, referred by Dr. M. L. Lewis, had suffered for two years prior to admission from frequent attacks of precordial distress, clinically diagnosed as angina pectoris.

Although for several years the patient had had only occasional attacks of angina pectoris, in the late fall of 1934 they increased in frequency, averaging one daily until Jan. 10, 1935, when he went to Dallas for consultation. From there he came to Baltimore for further study and observation. During this period he did not have a single attack nor did he have any while under our observation, a period of two weeks. On examination Feb. 6, 1935, he was unable to recollect having had a single attack during the summer months when not exposed to carbon monoxide. This fact led to the assumption that carbon monoxide was a factor in the production of his anginal attacks. Further inquiry revealed a history of exposure to carbon monoxide over a period of twenty-five years. His house was heated by natural gas in open heaters, inadequately ventilated. For the previous five years he had been exposed also in the gas and oil fields; besides, he frequently detected escaping gas in his automobile while driving with the windows closed.

In addition to anginal attacks, he complained of symptoms of anoxemia: dyspnea, palpitation, weakness in the legs, unsteady gait, cramps in the calf muscles, headache, vertigo, cardiospasm and paresthesia. He used alcohol and tobacco moderately, drank coffee to excess and overworked.

His blood pressure was 102 systolic and 80 diastolic, his pulse rate 66 and his temperature subnormal. The heart was slightly enlarged, with an occasional dropped beat and reduplication of the second sound. No murmurs were heard. The blood vessels appeared normal for a man of his age.

Laboratory studies showed mild glycosuria, a blood sugar content of 174 mg. per hundred cubic centimeters, a basal metabolic rate of minus 21 per cent and a negative Wasser-

mann reaction. A blood count showed hemoglobin content 81 per cent, red cells 4,780,000 and white cells 8,250.

Electrocardiographic study by Dr. King revealed an abnormal tracing suggestive of myocardial degeneration, possibly of coronary origin. The diagnosis of angina pectoris was confirmed by Dr. L. F. Barker.

By improving the heating conditions and adopting a more hygienic mode of living, the patient improved and remained free from anginal attacks for some months. He later had symptoms of myocardial degeneration with congestive heart failure.

CASE 4.—F. B., a man aged 60, a toll bridge executive and a resident of Pennsylvania, referred by Dr. Richard Miller, had had symptoms of carbon monoxide anoxemia for several years, and signs and symptoms of myocardial disease had recently developed.

Since November 1932 the patient had worked about seven hours daily in an office on a toll bridge, over which an average of 18,000 automobiles passed daily. Each motorist paused to pay the toll, thus exposing the employees to an enormous amount of carbon monoxide coming from the exhaust. A blood test made while the patient was on duty showed a carbon monoxide saturation of 27 per cent. A test made of the blood of five employees showed a carbon monoxide saturation ranging from 5 to 30.75 per cent, according to the length of time exposed. At the time of his first examination the patient manifested all the symptoms of severe anoxemia but the heart showed nothing abnormal.

Laboratory studies gave normal results, except that the basal metabolic rate was minus 23 per cent and the blood cholesterol content 92 mg. per hundred cubic centimeters.

Continuing to work in this environment, he later had symptoms of congestive heart failure, with dyspnea, palpitation, attacks of acute precordial pain of anginal character and extrasystoles. An electrocardiogram made June 25, 1937, showed auricular fibrillation. One made two months previously was perfectly normal. Periodic vacations of several weeks at the seashore always relieved his symptoms. On a recent examination the heart again appeared normal.

CASE 5.—S. C., a man aged 55, owner of a gas well, complained of acute precordial pain, with dyspnea and irregular heart action on exertion.

Seven years previously he had become conscious of a rapid and labored heart action on exertion, with a rate occasionally as high as 120 a minute. Two years previously his heart had begun to miss beats and at the same time he began to have anginal attacks, but only on exertion, as on going up hill.

The blood pressure was 122 systolic and 70 diastolic and the pulse rate 78 a minute. The peripheral vessels were slightly tortuous but not beaded. The heart was not enlarged and the sounds appeared normal.

The patient heated his house with nine open gas heaters, in which he burned the wet, unrefined gas. Tests made for carbon monoxide in the living and the dining room showed that the air contained enough gas to cause symptoms. After he was freed from exposure to carbon monoxide by the installation of a central heating plant he was relieved of his symptoms, including the anginal attacks.

Numerous other cases showing the relation of carbon monoxide to myocardial disease could be cited from our records.

In the majority of fatal cases the patient dies of acute asphyxiation, usually without regaining consciousness. In others the patient not only regains consciousness but apparently recovers from the acute symptoms and remains well for a few days, and then secondary manifestations suddenly appear. These manifestations are generally referable to lesions of the heart or of the central nervous system, to which the patient succumbs.

The chronic form of carbon monoxide anoxemia is represented by patients who survive the delayed effect, or sequelae, of the acute form. The cases reported

25. Liebmann, E.: Ein Fall von Herzmuskelerkrankung nach Leuchtgasvergiftung. Deutsche med. Wchnschr. 45: 1192, 1919.

were of this form, with residual cardiac symptoms. If the cause can be removed so that the patient is no longer exposed to the damaging effect of the gas, some patients will recover, symptomatically at least. This has been demonstrated by the electrocardiogram, which showed in many instances that conduction was restored to normal. The condition of other patients will progress into the chronic invalid type of myocardial degeneration, terminating in congestive heart failure and death.

Carbon monoxide as a causative agent in producing myocardial disease may help to explain the seasonal incidence of coronary thrombosis, to which Wood and Hedley²⁶ called attention. They reported ninety-five cases observed in Philadelphia during the autumn and winter and only fourteen in the spring and summer. Master, Dack and Jaffe²⁷ observed that of 612 attacks 12.2 per cent occurred in January and 10.3 per cent in December. The increased combustion of carbon monoxide-producing fuel for motor power and heating and the increased danger from automobile exhaust gas and from improper ventilation during the cold months materially increased the hazard, thus rendering more persons susceptible to cardiovascular disease, including angina pectoris, coronary thrombosis, heart block and myocardial insufficiency.

SUMMARY

1. In a group of 136 persons who had been intermittently exposed to carbon monoxide over varying periods, myocardial symptoms were frequently manifested.

2. The lesions affecting the heart, brain and other organs are primarily vascular, consisting of small hemorrhages and perivascular infiltration with focal necrosis. When the heart is affected, coronary thrombosis frequently develops, as ascertained by postmortem and electrocardiographic studies.

3. Hemorrhagic lesions affecting the heart muscle have been produced experimentally in animals subjected to varying amounts of carbon monoxide in inspired air.

4. The impression that unless the patient dies in acute asphyxiation no harm may result is erroneous.

5. Patients who apparently recover from acute asphyxiation frequently have later manifestations, which appear in from three to seven days. These are known as delayed symptoms, or sequelae, and may affect the heart, brain or other organs and terminate fatally.

6. Those who survive the delayed manifestations may completely recover or ultimately may have severe organic disease of the heart or of other organs, to which they finally succumb.

7. Lesions may occur simultaneously in the heart and the brain, as evidenced by clinical studies and post-mortem observations.

8. In order to make a positive diagnosis of chronic myocardial disease resulting from carbon monoxide, it is essential that an accurate history be obtained with respect to exposure to gas, exhibition of symptoms of anoxemia, clinical course of the disease and absence of preexisting cardiac lesions.

ABDOMINAL MANIFESTATIONS OF THE HYPERACTIVE CAROTID SINUS REFLEX

J. EDWARD STERN, M.D.

NEW YORK

Abdominal manifestations of the hyperactive carotid sinus reflex appear to be uncommon. The manifestations to be described in this paper consisted of abdominal cramps and diarrhea, occurring in conjunction with other symptoms of severe autonomic disturbance and with syncope.

A brief sketch of the basic facts pertaining to the carotid sinus reflex is essential to an understanding of the subject. For detailed accounts of the problem one must consult the work of Waller,¹ Czermak,² Hering,³ Heymans,⁴ Roskam,⁵ Weiss and Baker,⁶ Braeucker,⁷ Ferris, Capps and Weiss,⁸ Smith and Moersch,⁹ and Åsk-Upmark.¹⁰ The recent paper of Weiss, Capps, Ferris and Munro¹¹ offers a concise and lucid account to which the reader is referred. Ability to recognize these cases clinically is due primarily to the work of Weiss and his associates.

The carotid sinus is the bulbous dilatation of the internal carotid artery at its origin. It is richly supplied with a plexus of nerve fibers which give rise to the carotid sinus reflex. The reflex can be sensitized by digitalis, inhibited in certain cases by atropine and sympathomimetic drugs, and abolished by extirpation of the plexus. The chief afferent pathways are through the intercarotid, glossopharyngeal, hypoglossal and vagus nerves and the cervical portion of the sympathetic chain. The stimuli traverse central synapses in the brain stem and innervate contralateral autonomic pathways, both central and peripheral, in a variable manner. It is these variants in the efferent paths that produce the different types of motor response resulting in convulsions and syncope.

These type responses have been classified by Weiss and his associates as vagal, depressor and cerebral. The vagal and depressor types are associated with decreased cerebral blood flow and cerebral anoxemia. The vagal reaction is associated with cardiac slowing or asystole and can be modified with atropine (by depression or paralysis of the vagi) and by ephedrine and epinephrine (by direct ventricular stimulation).

The depressor type is associated with symptoms due to reflex vasodilatation by way of the aortic depressor nerves and is modified by ephedrine and epinephrine but not by atropine. The cerebral type is not associated with decreased cerebral blood flow and the symptoms are probably due to a reaction in the vegetative centers of the hypothalamus, either directly or through the mediation of small vessels. Frequently combined vagal-cerebral and depressor-cerebral syndromes are observed. The commoner associated symptoms in order of frequency are dizziness and weakness, hyperpnea, facial pallor, bradycardia, numbness and tingling of the extremities, convulsions, drowsiness, cataplexy, epigastric distress, nausea, lacrimation, cough, amnesia and palpitation.¹⁰

It should be stated that the carotid sinus is but one of a number of vasosensory areas. It is not unlikely that others play a role in some disorders of analogous mechanism. The recognition of disturbances of the carotid sinus depends on the clinical accessibility of this structure. Its extirpation may abolish only one segment in a complex and widespread reflex arc, but, according to available data, this seems to be sufficient to produce the desired result in cases in which its hyperactivity has been definitely established.

The test for a sensitive carotid sinus should be carried out with some care and only one side should be stimulated at a time. The level of the bifurcation of the innominate and common carotid arteries is variable, although it is often behind the angle of the mandible. The carotid sinus is best located with the patient recumbent and the neck extended. It is then advisable to place the patient in a sitting or standing position, since the reflex is more easily evoked in this way. Several observations of the pulse and blood pressure are obtained until a base line is determined. Then pressure and massage of the sinus are carried out for from five to thirty seconds. Marked fall in blood pressure, slowing of the heart rate and general symptoms are evidences of a sensitive carotid sinus. Sudden loss of consciousness without alteration in the heart rate or arterial tension may also be indicative of hyperactivity of the carotid sinus reflex. It is extremely important to determine which of the two sinuses is the more sensitive, particularly in cases in which surgical intervention is contemplated. To exclude psychogenic factors the carotid sinus region is anesthetized with 1 per cent procaine hydrochloride; this procedure fails to abolish only those reactions which are psychogenic in origin. Stimulation of the carotid sinus has no effect in cases of narcolepsy, catalepsy, petit mal and grand mal.

After the diagnosis and classification have been established, medical therapy may be undertaken. For the vagal type of reflex atropine, ephedrine, epinephrine and benzedrine¹² are used. For the depressor type only the sympathomimetic drugs are useful. For the cerebral type, general measures—correction of systemic defects, avoidance of tight collars, fatigue and emotional upsets—are attempted. If medical therapy fails, surgical denervation of the sensitive sinus should be carried out unless some contraindication, such as local aneurysmal dilatation or sclerotic thinning, is present. The local presence of a mass, such as a tumor of the carotid body or a group of calcified nodes, of course constitutes a surgical indication. The operation consists in exposure of the carotid artery in the neck, careful stripping of the outer coat of the main arterial trunks for 2.5 cm.

below and above the bifurcation and removal of the tissue—including the carotid body—between the internal and external carotid arteries.

REPORT OF CASE

A man, aged 41, presented himself for examination Sept. 23, 1936. There was no familial history of any paroxysmal nervous disorder. At the age of 17 the patient was treated for pulmonary tuberculosis, which was subsequently stated to be healed.

The first of the attacks occurred in 1928 when he was 33. At that time, while crossing a street, he suddenly and unexpectedly experienced a sensation of tightness and fullness in the head. He became confused and noted sweating and drawing sensations in the hands. His face became flushed and he complained of throbbing in the head. He then lost consciousness, fell on the sidewalk and became incontinent of feces.

Attacks followed at the rate of from one to three a year. They were preceded by a brief aura of about five minutes' duration. The patient had never sustained any injury during an attack, and there were no known convulsions. It was not possible to determine with any accuracy the duration of the periods of unconsciousness. After a severe attack he would feel weak for two or three days.

Two physicians who had been summoned to give emergency treatment reported that during the attacks the pulse was very slow and irregular.

Rather intensive questioning failed to disclose any important psychogenic background. There was no history of constriction of the neck, as with a tight collar or pressure of the hand, preceding any of the attacks.

Sept. 20, 1936, at 7:30 p. m., the patient had another attack, which will be described in detail. Without antecedent nervousness, insomnia, constipation or ingestion of alcohol he experienced cramps in the lower part of the abdomen followed by an apparently normal bowel evacuation. On leaving the bathroom he noted a sensation of "blood rushing to the head" and his head seemed to "swell up like a balloon." While he was walking to his bedroom his fingers and toes began to tingle and sweat. He felt "uncertain and dizzy." His face was red but not blue; there was no foaming at the mouth. On reaching the bedroom he again experienced cramps in the lower part of the abdomen and attempted to return to the bathroom, where he fell unconscious into the tub, had a loose bowel movement and urinated. He was unconscious for from half an hour to an hour. There was no injury or biting of the tongue. A physician was summoned, who administered two hypodermic injections. At about 9 o'clock the patient regained consciousness, felt weak and stumbled into bed.

Physical examination September 23 was essentially negative. Neurologic and retinal examinations were likewise negative. The blood pressure was 120 systolic, 80 diastolic. X-ray examination of the skull showed no abnormality in the vault or sella. Radiographic examination of the chest showed small calcified and fibrotic deposits in both apical regions of the lungs, more marked on the left; there were old adhesions elevating the midportion of the left diaphragm. The basal metabolic rate was plus 9 per cent. The urine showed no abnormality. The blood count showed hemoglobin 106 per cent, red blood cells 6,380,000 per cubic millimeter and white blood cells 9,900, of which the polymorphonuclear neutrophils constituted 55 per cent, lymphocytes 39 per cent, eosinophils 5 per cent, basophils 1 per cent. The urea nitrogen content of the blood was 22.4 mg. per hundred cubic centimeters, sugar 100. The blood Wassermann and Kline reactions were negative. A routine electrocardiogram showed left axis deviation. With the patient holding a deep inspiration, the axis deviation was abolished, the R wave in lead 3 becoming large and the S wave small; a striking fall in pulse rate was noted.

The patient was seen by Dr. Israel Strauss, who expressed the opinion that idiopathic epilepsy and brain tumor could be excluded. During a subsequent joint observation, studies of the carotid sinus reflexes were made. Pressure on the right sinus produced a fall in blood pressure from 110-120 systolic and 70-80 diastolic to 80-90 systolic and 60 diastolic. The pulse rate fell from 84 to 60 beats per minute. In addition

12. Robinson, L. G.: Benzedrine Sulfate in the Treatment of Syncope Due to a Hyperactive Carotid Sinus Reflex, *New England J. Med.* 217: 952 (Dec. 9) 1937.

there were induced well marked symptoms such as the patient had experienced during the early stage of an attack: sensation of fulness in the head, tendency to labored breathing, numbness and sweating of the hands, tendency to unconsciousness. Even after stimulation for from twelve to fourteen seconds, however, unconsciousness and convulsions were not induced. Pressure on the left carotid sinus produced a similar fall in blood pressure and slight bradycardia but no abnormal subjective effects. The patient was instructed to take phenobarbital and atropine and to carry with him readily soluble tablets of atropine ($\frac{1}{100}$ grain, or 0.0006 Gm.) to take when a severe attack impended.

In December the patient had a severe attack, which he believed was somewhat modified by the use of atropine. From this time until the end of May 1937 he had two milder episodes without loss of consciousness.

May 26, at midnight, the patient entered his car to drive home. Nothing remarkable had occurred during the earlier part of the evening; he had taken one glass of beer. After driving for a few minutes through a congested district he "felt an attack coming on." The preliminary symptoms were those already noted in the description of the attack of September 1936. He took one tablet of atropine and stopped his car. He then attempted to leave his car to defecate. At this point he lost consciousness. At 3:30 a. m. he was seen by an ambulance surgeon and at 4 o'clock I saw him. He had regained consciousness but complained of pain in the back of the neck, of intense fatigue and of headache. He again stated that his head felt "like a balloon."

On examination the face was flushed. The patient was fully conscious but slightly drowsy. There was no pain on movement of the neck, and no meningeal signs. The lower part of the back and the buttocks were soiled with feces. The blood pressure was 130 systolic, 90 diastolic. The pulse rate was 84 beats per minute, pounding in quality. The pupils were equal in size and were not dilated; the left pupil reacted more sharply to light than the right. The mouth was dry (the patient had taken atropine). The knee and ankle reflexes on the left were somewhat more brisk than on the right. There was a neutral plantar response on the right; the response on the left was normal.

Six hours later the patient appeared fully recovered. The blood pressure was 110 systolic, 80 diastolic. The pulse was from 76 to 80 beats per minute. A sense of fatigue was present which cleared up in the course of the next three days.

June 6, 1937, the patient was seen by Dr. Soma Weiss, who confirmed the observations of the carotid sinus reflexes previously recorded. Procainization of the right carotid sinus abolished its reflexes. The surgical indications were analyzed as follows: 1. Medical therapy with atropine, phenobarbital and, later, ephedrine had been essentially unsuccessful. 2. The velocity of evolution of the severe attacks precluded successful self medication with atropine. 3. There was obvious inherent danger in some of these sudden attacks, such as the one recorded in which the patient was driving an automobile.

Consequently, surgical denervation of the right carotid sinus was carried out June 17 by Dr. Donald Munro at the Boston City Hospital. No gross pathologic changes were encountered. Recovery was uneventful. No subsequent attacks have occurred. Four months and six months after operation pressure over the right carotid sinus region produced no symptoms and no fall in blood pressure or pulse rate.

COMMENT

The interesting features of this case may be outlined briefly. There was nothing in the history to point to the carotid sinus as the origin of the widespread autonomic disturbances. However, in only approximately 25 per cent of cases is an important lead obtained in the anamnesis.^{2a} The avoidance of constriction of the neck by the use of loose collars is sometimes observed. Disturbances of the bowel such as occurred in this case are due, as has already been indicated, to severe widespread autonomic discharge with the afferent limb of the reflex arc in the carotid sinus. They are

relatively unusual and may further confuse the differential diagnosis between hyperactive carotid sinus reflexes and idiopathic epilepsy. It is not unlikely, however, that with more general recognition of these disorders more cases of this type will be observed. Of interest was the prolonged duration of the attacks of syncope noted in this case, since ordinarily these are of relatively short duration, usually lasting only a few minutes.

Further intensive study of this and related conditions is of great importance, since it opens to improved clinical approach the field of frank and borderline autonomic and vegetative disorders.

941 Park Avenue.

CONCENTRATED STREPTOCOCCUS (HEMOLYTIC) ANTITOXIC SERUM IN PUERPERAL FEVER

FURTHER THERAPEUTIC STUDIES

A. F. LASH, PH.D., M.D.

CHICAGO

Many years passed between the time that Pasteur (1878)¹ first cultivated the hemolytic streptococcus from a patient with puerperal sepsis and the time that attempts were made to combat the disease with serum. Of all the bacteria that may produce puerperal sepsis, the hemolytic streptococcus has been found the most common invader in the fatal types of the infection. Since 1895, when Marmorek² produced a serum which was supposedly valuable in the treatment of all types of streptococcal infections, other investigators³ employed polyvalent serums with discouraging results. Of all the types of serum therapy for puerperal sepsis subsequently reported,⁴ the most promising employed human convalescent serum.^{4b} However, the inadequacy of the supply made this mode of therapy impracticable.

The Dicks⁵ demonstrated the importance of streptococcus antitoxin in the treatment of scarlet fever by a controlled therapeutic study. In one series of patients with moderately severe attacks (thirty-five controls and twenty-one treated), there were no deaths, but a higher incidence of complications occurred among the controls, or untreated patients. In another series of patients with severe attacks (fifteen controls and twenty-nine treated), there was a mortality of 20 per cent in the control group and of only 3.4 per cent in the treated group.

The demonstration in 1925 of the production of toxin by hemolytic streptococci from patients with puerperal sepsis⁶ and the subsequent production of an antitoxin⁷ introduced a new and rational basis for serum therapy

Eli Lilly & Co. prepared the serum and furnished the author with an adequate supply for this study.

for puerperal sepsis. Subsequent clinical studies of the effect of the antitoxic serum on puerperal sepsis indicated its therapeutic value in the early stages.⁸ The contemporary studies of Warnekros, Louros and Becker⁹ and Gaessler¹⁰ corroborated the definitely favorable effect of treatment with antitoxic serum. That the serum was of value only when used early in the course of the disease was in accord with the experience with serum therapy for any toxin-produced disease, such as diphtheria, infection with *Bacillus welchii*, scarlet fever and erysipelas. Although an advance was made over the old antistreptococcus nonantitoxic serum, the therapeutic evaluation of the preparation was very difficult because of known spontaneous recoveries from streptococcal infections and the absence of any published studies checked by adequate controls. The present study, begun in 1928, was undertaken to check the value of serum therapy in a series of patients with puerperal sepsis in which alternate patients were treated with serum.

PREPARATION AND DOSAGE OF SERUM

The serum was prepared by immunization of horses with the toxin and organisms isolated from the blood and cervixes of women with severe puerperal sepsis due to the hemolytic streptococcus. The details have been

described in another study.⁸ The immune serum was utilized when a high antitoxic titer was demonstrated, as compared with scarlet fever antitoxin and after concentration. The initial dose was 40 cc. of the concentrated serum. It was given after the patient was tested and found to be free of idiosyncrasy to horse serum.

Patient	Character of Delivery	Onset of Puerperal Sepsis	Clinicopathologic Diagnosis	Bacteriology		Serum Therapy	Comment
				Cervix	Blood		
D. T., white, aged 25, P-I, G-II	Self induced abortion with catheter	3d day post abortion entered hospital; 104.2, 118, 22; chills, lower abdominal pain for 48 hours	Acute metritis; early peritonitis	Str. hem.	Neg.	5th day post abortion 40 cc. intravenously; 6th day post abortion 20 cc. intramuscularly; 7th day post abortion 40 cc. intravenously (104, 160, 44)	Died 8th day post abortion; generalized peritonitis; no autopsy
S. J., white, aged 21, P-I, G-II	Self induced abortion with catheter	5th day post abortion; pains in lower abdomen; 6th day post abortion entered hospital; 103.4, 124, 40	Acute metritis; early peritonitis	Str. hem.	Neg.	7th day post abortion 40 cc. intravenously; 8th day post abortion 40 cc. intramuscularly; 9th day post abortion 20 cc. intramuscularly	Died 12th day post abortion; autopsy: generalized peritonitis
M. M., white, aged 22, P-V, G-V	Forceps delivery at home followed by daily douches for chills, fever	6th day P.P. entered hospital; 104.4, 182, 32; toxic; abdomen slightly distended but soft	Acute metritis; early parametritis; peritonitis	Str. hem.	Str. hem.	7th day P.P. 40 cc. intravenously; 8th day P.P.; 40 cc. intramuscularly; 9th day P.P. 20 cc. intramuscularly; 10th day P.P. 20 cc. intravenously	Died 11th day P.P.; generalized peritonitis; no autopsy
M. S., white, aged 40, P-V, G-VI	Spontaneous delivery, 6 hours, 27 min. labor	3d day P.P.; 103.4, 120, 20; pain in lower abdomen	Acute metritis	Str. hem.	Neg.	8th day P.P. 60 cc. intramuscularly	Died 9th day P.P.; generalized peritonitis; no autopsy

The intravenous route was used if the patient was very toxic, but usually the intramuscular route was chosen. The same dose was repeated in twenty-four hours if the clinical course of the patient required it. A third dose of 20 cc. was given twenty-four hours later if necessary. From clinical experiences it was observed that as a rule 100 cc. of the concentrated antitoxic serum was sufficient to obtain a favorable response.

CLINICAL MATERIAL

The patients treated were all in the sepsis ward of the Cook County Hospital, having been delivered there or elsewhere. All of them had cultures taken of material from the cervix which yielded hemolytic streptococci. Cultures of the blood were also taken. In order for a patient to receive serum therapy or to be included in our series for study, the comprehensive diagnosis had to be puerperal sepsis, acute metritis, septicemia or toxemia, hemolytic streptococcus infection. Although the plan followed was to give serum to alternate patients, in compiling my statistics I found several more in the serum group, the reason being that

8. Lash, A. F.: *Am. J. Obst. & Gynec.* 17: 297 (March) 1929.9. Warnekros, K.; Louros, N., and Becker, M.: *München. med. Wehnschr.* 73: 2155 (Dec. 17) 1926.10. Gaessler, E.: *München. med. Wehnschr.* 75: 164 (Jan. 27) 1928.

the inclination of the house physician occasionally was to use the serum in cases of severe involvement despite the rule. All the patients fulfilled the criteria of having early severe sepsis on the basis of clinical, pathologic

and bacteriologic changes, as discussed in a previous publication on nomenclature.¹¹ There were forty patients in the treated group and thirty-three in the control group. Although the stage of the disease was judged early, on the basis of duration of fever and symptoms, careful examination and the clinical course demonstrated variations in the rate of the progression of the infection and resulting pathologic changes. Thus acute metritis and toxemia were usually present from three to five days after the onset of the infection, but in some instances generalized peritonitis or septicemia occurred within the same time. Therefore, the evaluation of the clinical material of puerperal sepsis was difficult, but these factors were considered in the analysis of the two groups. There were seven positive blood cultures for hemolytic streptococci in the control group and six positive blood cultures in the treated group.

The clinical statistics given in table 1 indicate a similar incidence of the usual etiologic factors of puerperal sepsis, particularly the high incidence of operative deliveries. Table 2 shows the incidence of the pathologic stages in the two series of patients studied when first seen. The diagnosis of early puerperal sepsis was a chronologic one; that is, a duration of from two to five days. The varying rate of progression of the infection during this interval is evident from table 2. The two groups of patients were, however, similar, allowing for the determination of the value of serum therapy.

The results of the antitoxic streptococcus serum therapy are given in table 3. The residual pathologic changes found clinically when the patients were discharged are also given. The favorable effect of the serum therapy is apparent in a comparison not only of the mortality but also of the incidence and extent of the residual pathologic changes. When the early cases of my last report were included, the total number of patients treated was sixty, with a mortality of 8 per cent (five patients), and there were forty-four control patients, with a mortality of 48 per cent (twenty-one patients); the latter rate is comparable to the mortality reported by Fitzgibbon and Bigger¹² (51 per cent in fifty-seven patients not treated with serum).

The amount of serum used depended on the clinical response. Of the forty patients, twelve received 40 cc., nine received 60 cc., six received 80 cc., six received 100 cc., five received 120 cc. and one received 160 cc. No immediate reaction followed the use of the concentrated serum. Although the intravenous injection gave a quicker therapeutic response, the intramuscular route was most often chosen for the sake of safety. The difference in rate of absorption between the two may not be great, but the effect is much more striking with intravenous administration. Late serum sickness, that is, erythema, urticaria and swollen and tender joints, occurred from six to nine days after the administration of the serum in 40 per cent of the patients, which is a high incidence. No serious consequence followed the serum sickness, except in two patients: one had persistent sciatica and the other had toxic encephalitis (no organisms on smear or culture). They recovered, and the relation to serum therapy was dubious.

An analysis of the deaths in the treated group (table 4) shows that the cause of death was generalized peritonitis. The negative value of the serum in this group was not due to the delay in the administration of

11. Lash, A. F.: *Am. J. Obst. & Gynec.* 27: 793 (June) 1934.12. Fitzgibbon, G., and Bigger, J. W.: *J. Obst. & Gynec. Brit. Emp.* 32: 298, 1925.

the serum except in probably one instance (M. S.) but rather due to the rapidity of the extension of the infection (generalized peritonitis). It is again evident that serum is of no value in the treatment of this type of infection.

The deaths in the control group (table 5) may be considered as those due to early fulminant peritonitis and, in a larger group, to delayed development of peritonitis and other pathologic states. The assumption might be warranted that in the latter group the early use of serum might have prevented the progression to peritonitis and the other fatal complications (septicemia, thrombophlebitis and septicopyemia). There were no deaths from septicemia or thrombophlebitis with septicopyemia in the treated group.

Mention may be made of the procedure of sending an adequate supply of serum to ten different obstetric clinics for further clinical evaluation. The reports were incomplete and could not be used for any statistical study.

CONCLUSIONS

1. The value of antitoxic serum therapy in the treatment of early hemolytic streptococcus puerperal sepsis is demonstrated by the marked reduction in mortality and residual pathologic changes in a controlled series of cases.

2. The early diagnosis of hemolytic streptococcus puerperal sepsis is essential for the successful use of the antitoxic (hemolytic) streptococcus serum.

3. Failures despite early therapy may be due to the abnormally rapid progression of the infection (fulminant form of generalized peritonitis).

R. C. GASKILL, M.D.
Captain, Medical Corps, U. S. Army
WASHINGTON, D. C.

While studying a series of cases of syphilis of the central nervous system we were impressed by the number of patients who entered the hospital complaining of nausea, vomiting, hematemesis and epigastric pain. Complete study of these cases gave results which are at variance with our previous conceptions and constitute the basis for this report.

MATERIAL AND METHOD

All cases of syphilis of the central nervous system admitted to an active, large general hospital during a period of approximately four years were studied. Each case was examined by one or more of us. A few of these cases presented other primary causes for hospitalization, such as pulmonary tuberculosis. In each case complete examination facilities were utilized, so that gastric analyses and roentgenologic study of the gastrointestinal tract were accomplished in all indicated cases. All pathologic changes found on roentgen examination were verified after the administration of belladonna

From the Neuropsychiatric and Genito-Urinary Sections, Fitzsimons General Hospital, U. S. Army, Denver.

and atropine. Only patients in whom abnormalities were found on repeated roentgen examination and who had definite gastric symptoms were placed in the ulcer group.

All cases presented clear-cut neurologic, psychiatric and spinal fluid signs of syphilis of the central nervous system. A minimum of two examinations of the spinal fluid was made in each case included in the series. Wassermann and Kahn reactions of the blood were both obtained at least twice in each case. These sero-

logic reactions of the blood were negative or only incompletely positive in approximately 30 per cent of our cases. Cases incompletely studied or those presenting questionable clinical conditions were excluded from the series. This accounts for an additional thirty-seven cases. Two hundred cases of syphilis of the central nervous system remained for study.

The controls for our observations on these patients with syphilis of the central nervous system were three other groups of patients in the hospital during the period of study. The method of study was identical with that outlined for the neurosyphilis group. These control groups consisted of:

1. Two hundred patients with latent syphilis. Each of these patients repeatedly had completely positive blood Wassermann and Kahn reactions without any demonstrable clinical or serologic involvement of the cardiovascular or central nervous systems.

2. One hundred patients with pulmonary tuberculosis, none of whom had syphilis.

3. One hundred patients consecutively admitted to this hospital.

In addition to the basic study of 200 patients with syphilis of the central nervous system and the control groups, we studied the records of 100 patients with peptic ulcer, who had been examined and treated in the hospital, for evidence of syphilis of any type.

OBSERVATIONS

The incidence of peptic ulcer in our series of cases of syphilis of the central nervous system was 10.5 per cent, while this condition occurred in the control series in from 1 to 3 per cent of the cases, as shown in table 1.

The characteristics of peptic ulcer as we observed them in our series of patients with syphilis of the central nervous system were of interest and, we believe, of significance. The symptoms presented in this group were characteristic of ulcer of the duodenal, gastric or anastomotic areas. The roentgenologic aspects were those of peptic ulcer of these areas without reference to any underlying or accompanying systemic disease. The gastric analyses were, however, of considerable interest in that thirteen of the twenty-three patients having both syphilis of the central nervous system and peptic ulcer had repeatedly low determinations of total and

clinically or roentgenologically to differentiate syphilitic from nonsyphilitic ulcerations.

Several workers have engaged in prolonged arguments over the validity of so-called biopsy-proved cases of syphilis of the upper gastrointestinal tract. Thus Singer¹³ is skeptical that McNee's¹⁴ case is one of true syphilis of the stomach. Harris and Morgan,¹⁵ however, appear to have definitely established the existence of syphilis of the stomach as an experimental, if not a clinical, entity. Unfortunately, some of the cases of so-called syphilis of the gastrointestinal system reported are diagnosed on questionable evidence.

We are not able, from our data, to correlate the many divergent views on the subject of involvement of the upper gastrointestinal tract by syphilis. From our data it is clear, however, that peptic ulcer occurs with significant frequency in cases of syphilis of the central nervous system. It is interesting to note that Hunt and Lisa¹⁶ also noted the occurrence of the two conditions in the same patients but they reported their observations as clinical curiosities. Since we found no increase in the incidence of peptic ulcer in our patients with syphilis without involvement of the central nervous system, we have no justification for regarding peptic ulcers occurring in syphilitic patients as necessarily syphilitic in origin. This view is further confirmed by our failure to find an increased incidence of somatic syphilis in our patients known to have peptic ulcer.

Cushing's⁴ observations suggest the possibility that syphilis of the central nervous system is an etiologic factor of significance in our cases of peptic ulcer. Instead of gastric hyperacidity, however, as would be anticipated from Cushing's nerve irritation theory, we noted gastric hypo-acidity (table 2) in a significant number of our cases. We did note gastric hypermotility in all our ulcer cases. Rivers¹⁷ has suggested that "peptic ulcer is the result of several interacting and variable factors." Since syphilis may involve not only the central nervous system but also the vascular system, it is possible that abnormalities of both these systems played a part in the production of the peptic ulcers we found. The work of Mayo,¹⁸ of Reeves¹⁹ and of Wilkie²⁰ all show clearly the significance of vascular pathologic changes in the etiology of peptic ulcer. Among our twenty-one patients with syphilis of the central nervous system and peptic ulcer, nine also had syphilis of the cardiovascular system of such severity as to preclude treatment by fever therapy. The possibility that the role of syphilis in the production of such peptic ulcers is by involvement of the central nervous and vascular systems is interesting but is not proved by our data.

CONCLUSIONS

1. There is a greater incidence of peptic ulcer in patients with syphilis of the central nervous system

than in those with latent syphilis or pulmonary tuberculosis without syphilis or in unselected hospital patients.

2. Syphilis does not appear to be of direct etiologic significance in such cases.

3. The incidence of peptic ulcer in cases of neurosyphilis in this series (10.5 per cent) is much higher than that reported from other clinics.

St. Elizabeths Hospital.

VITAMIN D COMPLEX IN KERATOCONUS

ETIOLOGY, PATHOLOGY AND TREATMENT OF
CONICAL CORNEA: PRELIMINARY REPORT

ARTHUR ALEXANDER KNAPP, M.D.

NEW YORK

Graves¹ describes keratoconus as "a hyperbolic bulging of the central part, or whole, of the cornea, with thinning of the center, unaccompanied by inflammation or increased tension." In a recent paper from the department of pharmacology of Columbia University College of Physicians and Surgeons, Blackberg and I² reported the consistent production of keratoconus in dogs fed a vitamin D deficient, low calcium diet. We have repeated these experiments on rats this past winter and have noted similar results.

In our experiments on dogs, we enucleated the eyes of some of them. These eyes were examined microscopically. The results of our pathologic examinations, corroborated by Drs. Reese and Laidlaw, have been published.³ The basic changes in the corneas were thinning of the epithelium, edema of the substantia propria with irregularity of its lamellar structure and reduplication of the endothelium, with hydropic degeneration.

Nineteen eyes (twelve patients) with keratoconus are included in this study. One patient is presented so that the marked ectasia of the right cornea before beginning treatment may be observed. The other eleven patients have been treated for periods ranging from three months to three years. Of these eleven, seven have bilateral involvement. Four show the condition to be present in one eye and absent in the other. Of these four, three have a right keratoconus and one a left. There is a range from the slight degree of conical cornea, not readily made out, to the very marked case with perforation of the posterior layers of the membrane, epithelial cyst formation and central opacity.

Vitamin D, in the form of viosterol, and calcium, in the form of mineral mixture tablets, were prescribed.⁴

Assistance was given by Miss Diana Shrage of the New York Eye and Ear Infirmary.

This work has been financed through the kindness of the Mead Johnson Company of Evansville, Ind.

From the New York Eye and Ear Infirmary and the Montefiore Hospital, through the generosity of the attending eye surgeons of these two institutions.

Read before the New York Academy of Medicine, Section on Ophthalmology, Dec. 20, 1937, and the North Jersey Academy of Medicine, Section on Ophthalmology, May 9, 1938.

Dosage of the latter varied with the milk intake. If a patient drank one quart of milk daily, one tablet was prescribed. For each glass less than this, two tablets were added. The calcium was taken before breakfast, in one dose. As a routine, sixty drops of viosterol was given daily, after the morning meal. Lately the dose has been increased to 200 drops in some cases. No other change was made in the diet or regimen.

COMMENT

All of the eleven patients treated with viosterol and mineral mixture tablets have improved subjectively and objectively. Subjectively there is improved vision. Objectively there is corresponding improvement. Refraction, macroscopic, corneal microscopic and ophthalmometric examinations were done to give an adequate index of how much progress had been made. Recently, to be more accurate, I have been using plaster-of-paris casts of the anterior segments of the eyes, before and after treatment. Six molds were made of the eyes of three patients before this therapy was started and then repeated three to six months later. Without exception the later casts showed the cones to be flatter, with less of a hyperbolic curve. With the assistance of Prof. Carlos de Zafra of the engineering department and Prof. Louis Granath of the physics department of New York University the relative height of the corneas was measured.

More detailed examination shows that in five of the six eyes—both eyes of patients 1 and 2, and the right eye of patient 3—a reduction in the height of the cone took place. The sixth—the left eye of patient 3—showed an increase. These figures may represent an underestimation of the decrease in the height of the cones, for it must be remembered that the underlying pathologic condition of keratoconus in dogs, and probably in man too, is edema of the cornea; and with the type of measurement employed, a standard base line of fixed length, a greater chord of the shrunken globe after treatment would be included in the examination. Thus it can be seen that the eye which apparently had a more pronounced protrusion after the treatment had been taken for three months; actually may have had a less prominent cone. The twelfth patient brings out this point more vividly. She has been taking viosterol and mineral mixture tablets for three years. At the onset, both interpalpebral fissures were approximately equal in the vertical meridian. She had a severe keratoconus of the right eye, with epithelial cyst formation, and a mild myopia in the left. Today there is a definite ptosis of the right upper lid. Probably this ptosis is due to a shrunken globe; for in a subsequent paper I will show, by actual measurements, that the sclera, too, may undergo shrinkage after the administration of this therapy.

CONCLUSION

A consideration of this material suggests that the calcium-phosphorus metabolism is an important factor in the development of the cornea. It would appear that the lack or deficiency of these metabolic factors would favor weakness of the membrane. This weakness then may manifest itself as a primary, noninflammatory ectasia of the cornea. The administration of vitamin D and calcium in this condition has given gratifying results. In fact, the results apparently are so encouraging that it may be we have come upon a factor or the factor in the etiology of this perplexing pathologic condition. It is true that but eleven patients (eighteen

eyes) with a rare condition have been treated. Still, the regular decisive improvement of all suggests that the vitamin D complex has a definite place in the therapy of keratoconus. It is hoped that further observations along this same line will serve to give a more conclusive conception of its place in our understanding and treatment of keratoconus.

BENZEDRINE SULFATE

ITS LIMITATIONS IN THE TREATMENT OF THE
SPASTIC COLON AND A PHARMACOLOGIC
STUDY OF ITS EFFECTS ON THE
GASTROINTESTINAL TRACT

DAVID H. ROSENBERG, M.D.

ROBERT A. ARENS, M.D.

PHILIP MARCUS, M.D.

AND

HEINRICH NECHELES, M.D., Ph.D.

CHICAGO

Since the advent of benzedrine as a useful topical applicant to the nasal mucosa, benzedrine sulfate (benzyl methyl carbinamine sulfate¹), by virtue of its central stimulating action, has been exhibited for the relief of so many symptoms and disorders as to become almost a panacea. Such excellent reviews of the literature have already appeared, notably by Wilbur, MacLean and Allen² and by the Council on Pharmacy and Chemistry of the American Medical Association³ as well as an editorial in the *British Medical Journal*⁴ that similar summaries would at this time be wholly supererogatory. Suffice it to say, benzedrine sulfate appears to be of definite value in the treatment of narcolepsy and post-encephalitic parkinsonism and, only to a restricted degree in the management of certain mild depressive states and in some cases of chronic exhaustion. Although it has been reported as beneficial in the treatment of orthostatic hypotension,⁵ migraine⁶ and syncope due to a hyperactive carotid sinus reflex,⁷ the number of patients studied have been too few to permit of any conclusions. More recently, Lesses and Myerson⁸ found it helpful in the treatment of obesity.

Myerson and Ritvo⁹ directed attention to the value of benzedrine sulfate in relaxing spasm of the gastrointestinal tract and pyloric sphincter. Its gastric effects

Aided by the Oscar Aberle and Otto Baer funds.

Read before the Chicago Society of Internal Medicine, Jan. 24, 1937.

J. Roentgenol. 26: 868 (Dec.) 1936.

included a moderate decrease in tonicity and a decrease in the emptying time; peristalsis diminished little if any, although in some cases it was increased. Hence, they advocated it as a roentgenologic aid in the differential diagnosis between functional and organic spasm. Therapeutically, they found it efficacious in the treatment of "spastic colitis" and pylorospasm. Smith and Chamberlin¹⁰ observed a delayed emptying of the stomach and delayed motility of the small intestine and noted relaxation of spasm of the the duodenum and of the colon.

In an effort further to define its scope of usefulness, we undertook a cooperative study of its value in the treatment of the spastic colon ("unstable colon," "irritable colon") and of its pharmacologic action on the stomach, small intestine and colon.

SPASTIC COLON

Method.—Careful, detailed histories were taken and complete physical examinations, including a blood count, analysis of the urine and stool, an Ewald test meal, Wassermann and Kahn tests, cholecystograms and roentgenographic studies of the gastrointestinal tract were made in all cases. Only those patients presenting no physical abnormalities other than a spastic, irritable colon were selected for therapy. All patients with the exception of two (1 and 3) had been receiving but were refractory to the usual orthodox regimen (bland diet, atropine sulfate or belladonna, and sedation). Sedatives and antispasmodics were discontinued, and benzedrine sulfate (from 5 to 10 mg. orally) was substituted before breakfast and before lunch; in three cases an additional 10 mg. dose was taken before supper.

Results.—Of eighteen patients who were treated with benzedrine sulfate, three were improved, one noted improvement followed by a recurrence while taking the drug, eleven were unimproved, and in three the symptoms were aggravated (table 1). The results obtained were both unpredictable and varied, for in some cases improvement followed the administration of from 15 to 30 mg. daily (cases 1, 2 and 3), while in others untoward effects and exacerbations occurred after as little as 10 mg. (cases 16 and 17). Increasing the dose to as much as 30 mg. orally afforded no benefit when smaller doses were ineffective, notwithstanding the production thereby of undesirable side effects (cases 4 and 10). It is noteworthy that the patients manifesting improvement presented symptoms of lesser severity than the others and that those individuals reporting exacerbations of their symptoms possessed, in common, a more unstable, poorly integrated personality. Paradoxically, the duration of illness seemed unrelated to the therapeutic outcome.

Patient 5, unrelieved by benzedrine sulfate, subsequently responded well to the combined use of sodium bromide, bismuth subcarbonate and calcium gluconate. Patient 16, whose symptoms were intensified, noted distinct improvement when sodium bromide and atropine sulfate were substituted for benzedrine sulfate. Of interest is the diminished frequency and intensity of menopausal flushes and perspiration reported by patient 3, and relief of dysmenorrhea by patient 4.

Untoward effects, recorded by most observers and differing only in their nature, intensity and incidence, were noted in ten cases, although in three of these the effects were transitory. The more common symptoms were exhilaration, increased alertness, insomnia and

dryness of the mouth and throat. The other symptoms were diverse and included marked weakness, dizziness, faintness, intense headache, tremor, palpitation, dyspnea, tachycardia, anxiety, increased irritability, numbness, pollakiuria and transitory deafness. A fine papular, erythematous rash appeared on the face, neck and upper extremities of patient 10 three and a half hours after the onset of a severe reaction to 30 mg. of benzedrine sulfate orally and was accompanied by itching and tingling of the skin; a temperature of 95.5 F. by mouth was recorded an hour and a half later. In all cases these effects subsided within twenty-four hours.

Roentgenologic Observations.—The action of benzedrine sulfate on the colon was studied roentgenographically¹¹ in five cases (2, 8, 9, 11 and 12). Myerson

Fig. 1 (case 9).—Physiologic variations in the pattern of the colon when two successive enemas are given (A and B; C and D). The barium enema following 30 mg. of benzedrine sulfate orally (D) shows no greater degree of relaxation in the transverse and descending colon than the control (B) one day earlier. The spasm in the ascending colon and hepatic flexure in the control B is not present in the controls A and C.

and Ritvo⁹ observed roentgenoscopically that, following the oral administration of benzedrine sulfate, in cases of spasticity of the colon, a subsequent barium sulfate enema may be given more rapidly and with less discomfort and that the lumen of the colon is increased, the haustrations are broader and shallower and the contractions and irregularities are markedly diminished, if not abolished.

It is a matter of frequent observation, however, to note such changes with a second barium sulfate enema after a period of rest and without any medication. Hence patients 8 and 9 were given a barium sulfate enema and a film of the colon was taken. Fifteen minutes after evacuation this procedure was repeated. On

10. Smith, O. N., and Chamberlin, G. W.: Benzedrine Sulfate: Its Effects on the Motor Function of the Digestive Tract, on Gastric Acidity, and on Evacuation of the Biliary System, *Radiol.* 29: 676 (Dec.) 1937.

11. Drs. S. D. Mesriow and Philip Levitsky assisted in the radiographic work.

the following day, similar examinations were made, 30 mg. of benzedrine sulfate being given fifteen minutes before the second enema. In case 9 the second enema without medication (fig. 1 B) shows less marked and fewer haustrations and the lumen of the colon is broader than that of the preceding enema (fig. 1 A),

spasm in the ascending colon in the other control films (A and C) illustrates clearly the normal variations in the pattern of the colon from day to day and from one observation to the other. In case 8 the film taken after benzedrine shows a wider lumen in the descending and transverse colon and a contracted ascending colon and

TABLE 1.—Results in the Treatment of the Spastic Colon

Patient			Symptoms and Duration	Benzedrine Sulfate	Effects		Comment
No.	Age	Sex			Gastrointestinal	Miscellaneous	
1	50	♀	Right lower quadrant and umbilical pain; bloating, constipation; chronic exhaustion; 3 yrs.	10 mg. three times a day for 4 wks.	Improved	Nose, mouth and throat very dry	No previous therapy
2	40	♀	Right lower quadrant pain, 3 wks.; belladonna, bromide and diet ineffective	10 mg. and 5 mg. daily for 1 wk.*	No pain since benzedrine was started	1 yr. ago symptom* relieved by belladonna, bromide and diet
3	50	♀	Sharp lower abdominal pains after meals for years; 2-3 bowel movements daily; 1 mo.	10 mg. and 5 mg. daily for 1 wk.*; 10 mg. twice a day for 1 wk.	Pain disappeared in 1 day; b.m.'s. normal after larger dose was given	Nose, mouth and throat very dry	Hot flushes (menopausal) less frequent and milder
4	33	♀	Right lower quadrant pain and diarrhea when tired, 1 mo.; bland diet and atropine gave much relief but not complete; mucus 4+	10 mg. and 5 mg. daily for 7 days, then 10 mg. twice a day*	No pain after 4 days; recurred in 12 days while on benzedrine; mucus as before	Peppler and tender; less tired; 20 mg. daily caused headache 4+; very irritable, more alert	Same symptom* 2 yrs. ago; complete relief by belladonna and bromide; dysmenorrhea relieved
5	33	♂	Epigastric pressure; flatulence; "pencil" stools; tiredness 4+ off and on; 3 yrs.	10 mg. and 5 mg. daily for 12 days*	Unimproved	½ hr. after 10 mg. felt "peppy" for 1 hr.	Improved on bromide, bismuth sub-carbonate and calcium gluconate
6	20	♀	Marked constipation; occasional cramps and diarrhea; mucus; chronic exhaustion; 1 yr.; refractory to all therapy	5 mg. twice a day for 4 days; 10 mg. twice a day for 10 days	Unimproved	Basal metabolic rate -2
7	19	♀	Severe abdominal cramps; bloated; constipation; mucus, 1 yr.; refractory to all therapy	10 mg. twice a day for 2 wks.	Unimproved
8	39	♀	Nausea; abdominal pains; exhaustion; 1 yr.	10 mg. twice a day for 17 days	Unimproved	Exhaustion improved for 1 wk.; then relapse
9	27	♀	Abdominal pains; alternating constipation and diarrhea; mucus; marked diffuse abdominal tenderness; tired; 8 mos.	10 mg. twice a day for 4 wks.	Unimproved	Frequent urination; tiredness unimproved
10	29	♀	Right lower quadrant and umbilical pains; bloating; alternating constipation and diarrhea 4+ mucus; tired; weak; 2 yrs.	10 mg. and 5 mg. daily for 7 days; 10 mg. twice a day for 7 days; 10 mg. three times a day for 7 days	Unimproved	30 min. after 50 mg.: tremor, severe abdominal cramps, "faintness," numbness, dizzy, pressure in head, diminished hearing; very weak, rash; temperature 95.5 F., nausea
11	36	♀	Abdominal cramps, diarrhea mucus, bloating, constipation, tired; 3 yrs.	10 mg. twice a day for 24 days	Unimproved	Tiredness unimproved
12	34	♀	Abdominal cramps, recurrent diarrhea, urgency, mucus, distention, nausea; 2 yrs.	10 mg. twice a day for 24 days	Unimproved	Temporary insomnia, palpitation and dyspnea; mouth dry
13	50	♀	Abdominal cramps, diarrhea, mucus 4+, diffuse abdominal tenderness; 6 yrs.; refractory to all therapy	10 mg. twice a day for 8 days	Unimproved
14	46	♀	Epigastric cramps, fullness, diarrhea and urgency after meals; 7½ yrs.	10 mg. and 5 mg. daily for 1 wk.*; 10 mg. twice a day for 1 wk.	Unimproved
15	42	♀	Generalized abdominal pains, and constipation	10 mg. twice a day for 1 wk.; 10 mg. three times a day for 1 wk.	Unimproved
16	25	♀	Epigastric cramps; alternating constipation and diarrhea; mucus; exhaustion; 1 yr. off and on	10 mg. twice a day for 1 day	Pain and diarrhea increased	Markedly weak, dizzy, "faint," palpitation, tachycardia, tremor and anxiety 3 hrs. after 1st dose; lasted 20 hrs.	Bromide and atropine resumed; improvement
17	19	♀	Abdominal pains, diarrhea, urgency, mucus 4+; 4-5 yrs.; refractory to all therapy	5 mg. twice a day for 1 day	Severe cramps; diarrhea increased	"Exhilaration"; insomnia
18	33	♀	Abdominal cramps; alternating constipation and diarrhea; mucus; 8 yrs.; drowsy, exhausted	10 mg. twice a day for 2 wks.	Pain increased; developed mild right upper quadrant pain; b.m.'s. unchanged	More alert; insomnia; dry mouth

* Ten mg. before breakfast, and 5 mg. before lunch.

thus demonstrating the physiologic effect sometimes noted with successive enemas, as previously referred to. Following benzedrine sulfate (fig. 1 D), little if any change can be demonstrated when compared with the preceding control enema (fig. 1 C). When the filling of the colon following benzedrine (D) is compared with that of the control (B), the latter shows a slightly wider lumen in the descending colon and spasm of the ascending colon and hepatic flexure. The absence of

cecum, the number of haustrations in the transverse colon being the same as in the control (fig. 2). It is worthy of note that the spasm in the ascending colon may in itself, by distal expulsion of the barium, account for the wider lumen in the transverse and descending colon, without the latter being ascribed to a benzedrine effect.

A different series of observations were made in cases 2, 11 and 12. A barium sulfate enema was given on

one day, and the film taken was used as a control. Two days later this procedure was repeated, 30 mg. of benzedrine sulfate being administered orally twenty-five minutes before the enema was given. In case 2 no apparent change in the pattern of the colon was noted following benzedrine, yet clinically distinct improve-

Fig. 2 (case 8).—Control (A) followed by second enema (B) fifteen minutes after 30 mg. of benzedrine sulfate orally. Apparent relaxation of the transverse and descending colon with contraction of the ascending colon and cecum following benzedrine (B).

ment was reported (table 1). In case 12 there appeared to be little if any effect other than slightly increased spasm in the descending colon and better filling in the

ascending colon. Patient 11 showed definite relaxation of the colon following benzedrine (fig. 3), although no improvement was manifest therapeutically (table 1).

PHARMACOLOGIC STUDY OF THE EFFECTS OF BENZEDRINE SULFATE ON THE STOMACH AND SMALL INTESTINE OF DOGS

A study on dogs was undertaken first in order to exclude "reversal" effects with increasing doses of benzedrine and, secondly, in order to analyze the action of this drug more closely than could be done on human subjects.

All dogs used were thoroughly trained to our procedures. They were used only twice a week and the interval was sufficient for complete emptying of residual

barium from the bowels. Before and after every experiment controls were performed without drugs, and only such experiments are reported in which the dogs appeared to be in good health and in which the controls were uniform. The barium meal was given by stomach tube and consisted of 130 Gm. of barium sulfate, 30 Gm. of dried whole milk (Klim)¹² and 300 cc. of water. This meal was found to be very satisfactory and to yield rather constant control values. The emptying time was counted from the first appearance of barium in the duodenum until from 95 to 100 per cent of the barium had left the stomach. Benzedrine sulfate was given by subcutaneous injection at the time of the barium meal. In a number of tests roentgenograms were taken in addition to the fluoroscopic observations. Forty-five tests with benzedrine sulfate and more than 200 control observations were performed on six dogs.

From table 2 it appears that in most experiments a delay in emptying occurred with small and large doses of benzedrine sulfate and that the prolongation of the emptying time was roughly proportional to the dose. According to body weight, the dose of 5 mg. in dogs 2, 3, 7, 8 and 9 corresponds approximately to the dose of 30 mg. given to human beings. In a few experiments the emptying time was shortened. It is not believed, however, that this represents a true reversal effect, because the changes were too inconsistent (e. g., dog 8 in table 2). For approximately fifteen minutes after injection of benzedrine sulfate the stomach emptied with normal speed; thereafter an almost complete closure of the pylorus occurred, which lasted from an hour to an hour and a half. This was true for doses from 0.5 to 30 mg., but with the smaller doses this effect was of shorter duration. From ninety to 120 minutes after injection practically normal emptying was resumed. While the stomach appeared to have less tonicity when its emptying was inhibited by benzedrine, nevertheless waves of peristalsis were observed (figs. 4 and 5). These were not able, however, to propel

Fig. 3 (case 11).—Barium enema on different days. A, without benzedrine; B, twenty-five minutes after 30 mg. of benzedrine sulfate orally. Relaxation of the transverse colon (B) apparent. Clinically no improvement.

barium through the pylorus. Neither tilting of the dogs nor manual pressure exerted on the stomach was effective in forcing barium into the duodenum. At the time when more or less complete arrest of emptying of the stomach occurred, the duodenal cap, which was usually seen in our controls, was not visible; further, we observed during this time a state of spasticity of the

12. The Borden Company supplied the Klim for this study.

small bowel and an arrest of propulsion, with a thinning and in part beady appearance of the barium, which before was present in large, more or less continuous masses. The spasm of the small intestine disappeared when the effect of benzedrine wore off and normal emptying of the stomach was resumed. This observa-

Fig. 4 (dog 3).—Upper row: controls thirty, sixty, ninety and 120 minutes following barium meal; lower row: thirty, sixty, ninety and 120 minutes following barium meal and injection of 20 mg. of benzedrine sulfate. At the end of thirty minutes a second injection of 5 mg. of benzedrine sulfate was given. Note the disappearance of the duodenal cap and the contraction of the small intestine at the sixty and ninety minute periods as compared to the control. A lump of barium is retained in the descending part of the duodenum, and the barium in the small intestine appears discontinuous, thinner and in parts beady.

tion of a spastic contraction of the small intestine was more apparent when the benzedrine sulfate was injected thirty or sixty minutes after the giving of the barium meal. In the latter experiments a considerable amount of barium had by this time left the stomach and had accumulated in the small intestine in large, more or less continuous masses. Approximately fifteen minutes after injection propulsion of these masses ceased, and they assumed a streaky, beady appearance as already described.

In view of these observations, the emptying time of the stomach was studied in two normal human subjects, the control observations of one day being compared with those noted three days later after 30 mg. of benzedrine sulfate administered with the barium meal. In both cases benzedrine prolonged the emptying time approximately one hour. Spasm of the pylorus appeared fifteen minutes after the administration of benzedrine and lasted thirty minutes, and motility of the small intestine was delayed, thus concurring with the studies on dogs.

COMMENT

The disappointing clinical results observed in the treatment of the spastic colon are at variance with the beneficial effects reported by Myerson and Ritvo,¹³ but find corroboration in the variety of antithetic symptoms noted by Davidoff and Reifstein.¹³ Moreover, the diverse effects observed roentgenographically and herein recorded afford some explanation of our clinical failures and leave much to be desired therapeutically.

It must be pointed out that in the treatment of this disorder, the symptoms of which are so closely correlated with the psychic state of the individual, very often the mere change to a bland diet, reassurance, warm applications to the abdomen, rest, relaxation or mild sedation will effect improvement and that, unless carefully controlled studies are conducted, evaluation of the efficacy of this drug is difficult. Further, the differentiation between the physiologic variations and the pharmacologic effect of benzedrine sulfate by means of barium enemas may yield untrustworthy results, as indicated by the foregoing studies.

Pharmacologically, benzedrine has been described as a drug with prevailing effects through the sympathetic nervous system. It may therefore be that per se, like the closely related ephedrine,¹⁴ it produced in our dogs a contraction of the pylorus similar to that observed frequently following stimulation of the splanchnic nerves. The same mechanism may also have produced a relative relaxation of the distended stomach. Another explanation may be found in the observation of Luckhardt, Phillips and Carlson,¹⁵ who noted contraction of the pyloric sphincter resulting from mechanical irritation of the duodenum; this would apply to our results if we assume that benzedrine sulfate produced primarily a spasm of the duodenum. The biologic mechanism of benzedrine seems to be rather complicated, however, and in consequence of a number of fundamental differences between the pharmacologic effects of epinephrine and benzedrine, Tainter¹⁶ designated the latter

Fig. 5 (dog 7).—Same as in figure 4. The inhibition of emptying is more marked than in figure 4.

a pseudosympatheticotropic drug. From their studies on excised segments of the intestine of rabbits, rats, guinea pigs and cats, Detrick, Millikan, Modern and Thienes¹⁷

concluded that, for visceral structures, benzedrine is neither a true sympathicotropic drug nor a typical muscle stimulant. One of its most frequent side effects in patients is distinct dryness of the mouth, which may be due to an atropine-like action. Probably it also has a direct effect on muscle.¹⁸

From our observations in dog and in man, benzedrine sulfate does not effect a relaxation of the pylorus but produces pylorospasm, prolongation of gastric emptying time and spasm of the small intestine. Our results are thus opposed to those of Myerson and Ritvo,⁹ and in part to those of Smith and Chamberlin,¹⁰ who observed a release of pylorospasm following benzedrine in patients with ulcer and retardation of emptying of the stomach and small intestine in both normal persons and patients with duodenal ulcer. Spasm of other sphincters, namely urinary and rectal, has also been observed following the use of benzedrine sulfate.¹⁰

It is a frequent observation on patients that after a barium meal no gastric emptying occurs for periods up to fifteen minutes; transitory pylorospasm seems to be present and is believed by some to be due to apprehension and fear. Myerson and Ritvo⁹ noted that the effect of benzedrine sulfate on the pylorus began from five to ten minutes after oral administration, whereas Smith and Chamberlin¹⁰ noted almost immediate relaxation of spasm of the duodenum and colon after parenteral administration. This does not necessarily mean that these results should be ascribed to benzedrine, for in man (orally) and in dog (parenterally) we observed a period of approximately fifteen minutes before the drug became effective and a much longer period before its maximum action occurred. This, we believe, explains the discrepancy between our finding of pylorospasm and that of pyloric relaxation noted by the earlier observers.

SUMMARY AND CONCLUSIONS

1. Of eighteen patients with a spastic, irritable colon treated with benzedrine sulfate, three improved, one showed improvement followed by relapse, eleven were unimproved and three were worse. The lack of uniformity in its effects on the spastic colon, as observed roentgenographically in five patients, restricts its clinical usefulness to a considerable degree.

2. In two normal subjects and in the dog, benzedrine sulfate produced pylorospasm and enterospasm and prolonged the emptying time of the stomach and small intestine.

3. Benzedrine sulfate is not recommended in the treatment of spastic disorders of the gastrointestinal tract.

Bismarck Challenged Virchow.—For years Virchow was a member of parliament, where he was one of a group, including Mommsen, who were in opposition to Bismarck. In 1865 Virchow defeated the government on a motion to create a German navy, and Bismarck was so enraged that he challenged the professor. The chancellor informed the professor by letter that the minister of war would be one of his seconds. Virchow declined the challenge, saying that his life was too valuable to mankind to be put to the chance of a duel with a politician but proved his courage, ere many years had passed, by his promptitude in going to the front with the medical corps when the Franco-Prussian War broke out.—Carr, James G.: *Rudolph Virchow, Northwestern University Bulletin* 38:1 (Jan. 31) 1938.

HEMOPTYSIS IN MALIGNANT HYDATID MOLE

EDGAR R. PUND, M.D.

ROBERT B. GREENBLATT, M.D.

AUGUSTA, GA.

AND

CLEVELAND THOMPSON, M.D.

MILLEN, GA.

Pulmonary hemorrhage, when associated with a neoplasm elsewhere in the body, is a symptom fraught with great concern and is usually regarded as evidence of an early demise on the part of the patient. The portent of pulmonary hemorrhages when associated with invasive hydatid mole has not the same ominous prognosis. We have had the opportunity to study by repeated roentgen examinations and biologic hormone assays a patient with an invasive hydatid mole. In spite of

multiple metastatic (?) pulmonary foci and the resultant bouts of hemoptysis, she made an uneventful recovery following total hysterectomy.

REPORT OF CASE

A married white woman aged 22 was admitted to the Millen Hospital, Millen, Ga., Dec. 9, 1936, with backache, abdominal pain, irregular bleeding from the vagina of five weeks' duration and incessant vomiting

Fig. 1 (Jan. 14, 1937).—Circumscribed foci can be seen scattered throughout both lungs, particularly behind the first, second and third anterior interspaces on left. Biologic hormone assay for gonadotropic substance revealed 5,000 mouse units per liter of urine.

for three weeks. Eleven weeks had elapsed since her last normal menses. She lost 24 pounds (11 Kg.) and now weighed 114 pounds (52 Kg.). Examination revealed a uterus which was enlarged to the size of a three and a half months pregnancy. Pain and bleeding ceased with rest in bed and she was dismissed one week after admission. Jan. 11, 1937, she was readmitted to the hospital because of irregular bleeding, which had become profuse during the ten preceding days. Her weight was further reduced to 102 pounds (46 Kg.). Shortly after admission she had a pulmonary hemorrhage. Six hours later this was followed by a second but more profuse one. Pulmonary hemorrhages recurred every two or three days. The uterus was emptied of a hydatidiform mole, which was examined in the pathologic laboratory of the University of Georgia School of Medicine. Bleeding was so excessive as to necessitate packing of the uterus.

Fig. 2 (March 2, 1937).—Note the regression of shadows behind first anterior interspace on both sides. Focal mass still prominent behind right second interspace. Biologic hormone assay for gonadotropic substance revealed 150 mouse units per liter of urine.

The patient was given several blood transfusions. Roentgen study of the lungs January 14 revealed many focal nodules throughout both lung fields (fig. 1). January 15, biologic assay

of the urine for its gonadotropic content revealed 5,000 mouse units per liter.

January 21 a supracervical hysterectomy was performed and the specimen submitted to the University of Georgia School of Medicine for pathologic study.

The first specimen was a bulky hydatidiform mole. Microscopically there was pronounced proliferation of the Langhans cells. This suggested the possibility of invasion. When the uterus was removed it was found to be enlarged to one and a half times the normal size. Two small rounded hemorrhagic areas 1 by 1 cm. were found bulging the serosal surface on the posterior and fundal aspects of the uterus. The lateral serosal surfaces of the uterus showed a bluish mottled discoloration in contrast to the pinkishness of the remaining surfaces. On section

Fig. 3 (Jan. 15, 1938).—Note the disappearance of all focal masses throughout both lung fields. Friedman test negative Nov. 11, 1937.

tion the endometrial cavity and the inner muscular layer of the uterus, particularly near the fundal margins, were filled with a granular, spongy bluish gray tissue. The bluish areas were recognized as enlarged, hydropic villi. The underlying myometrium was deeply invaded by a few of the villi (fig. 4).

Many sections of the uterus revealed the myometrium invaded by villi covered by proliferating layers of Langhans' cells and syncytium. A marked syncytial cell reaction in the surrounding myometrium accompanied this process (fig. 5). In other sections villi were absent but occasional zones of syncytial cell hyperplasia were noted. In some of the venous sinuses, sheets of syncytial cells were observed (fig. 6).

The hemorrhagic nodules previously mentioned showed on section only blood cells and fibrin and were void of trophoblastic elements.

The diagnosis was invasive hydatid mole.

The lung fields were again roentgenographed Feb. 7, 1937 (fig. 2), and some regression of the focal pulmonary masses was in evidence. Another biologic assay of the urine at this

Fig. 4.—Uterus sectioned to demonstrate the invasiveness of the lesion and the site of the two hemorrhagic nodules.

time revealed but 150 mouse units of gonadotropic substance per liter.

On roentgen study of the chest June 15, 1937, the lung fields were clear. Repeated examination of the sputum for tubercle bacilli was negative.

The patient's convalescence was slow but steady and at the present time she is perfectly well.

No radiation therapy was ever attempted. A Friedman test performed Nov. 11, 1937, was negative. Roentgenograms of the chest Jan. 15, 1938 (fig. 3), showed complete regression of the tumor masses.

COMMENT

Schmorl first presented evidence that in pregnancy syncytial masses are often carried from the uterus and lodged in pulmonary and other capillaries. He found these detached cells in the pulmonary veins in 80 per cent of 150 eclamptic patients studied at autopsy. Schmauch,¹ in his exhaustive study on chorionepithelioma, emphasized that the mere presence of chorionepithelial cell masses inside of veins was no proof of a malignant condition. He gave notice that the destructive hydatid moles or placental polyps do not give rise to metastases but often lead to embolism of the lungs and villous infarcts of the vagina. Ewing² quoted Fleischman as having collected from the literature in 1905 seven cases of recovery from "chorioma" with pul-

Fig. 5.—Section of uterus. Note the invasion of the myometrium by villi and the accompanying marked proliferation of the Langhans cell and syncytium layers. In lower right corner a marked syncytial cell hyperplasia pervades the myometrium.

monary metastases. McClellan³ reported a case of atypical chorionepithelioma in which the patient during the course of her illness was seized with sharp pains in the left side of the thorax and began to cough with a bloody expectoration. Examination of the sputum showed syncytial cells. The patient recovered. Lackner and Leventhal⁴ recently reported a case of chorionepithelioma with pulmonary metastases and their patient recovered following extensive courses of radiation therapy.

3. McClellan, B. R.: *Tr. Am. Assn. Obst. & Gynec.* 38: 161, 1915, quoted by Rosenzweig, Maxwell: Syncytial Endometritis and Syncytiorrhoea, *Am. J. Obst. & Gynec.* 13: 563 (May) 1927.
4. Lackner, J. E., and Leventhal, M. L.: Chorionepithelioma of the Uterus, *J. A. M. A.* 98: 1136 (April 2) 1932.

Our patient made a complete recovery without any radiation therapy. This type of case is frequently interpreted as chorionepithelioma with pulmonary metastases in which spontaneous regression has occurred. We are inclined to regard such neoplasms as (locally) malignant hydatid moles and not as true chorionepitheliomas,⁵ although it is quite possible for chorionepitheliomas to arise from such growths. Deportation of syncytial masses or even villi are not infrequent catastrophes in invasive mole. These deportations often lodge in the lungs or vagina and are notoriously known to regress in the majority of instances, particularly after removal of the uterus.

In a process which normally impinges on and proliferates within blood spaces, an occasional pulmonary infarct should not prove astonishing. Therefore pulmonary symptoms, from a prognostic standpoint, should not be valued too highly. However, deported placental cells may proliferate. In molar pregnancy progressive changes will be found constantly in placental cells deported to the lungs, and even in partial mole Schmorl was able to demonstrate an invasion of the wall of blood vessels in the lungs by these cells. Transitory proliferation of these syncytial cells may take place, but their ultimate fate is demonstrated by the cicatrices frequently observed in such lungs. Ewing² doubted that malignant tumors could develop from deported, normal or originally harmless cells of the chorion and placenta.

SUMMARY

In a case of invasive mole, hemoptysis was a prominent feature. Roentgen studies of the chest revealed metastatic foci in the lungs. Following hysterectomy

Fig. 6.—A mass of syncytial cells lie free in one of the uterine sinuses.

and without radiation therapy, the metastatic pulmonary foci regressed and the patient recovered. The biologic hormone assay for gonadotropic substance in the urine was only 5,000 mouse units per liter before hysterectomy and 150 mouse units per liter three weeks after operation. These low hormonal values were in harmony with the regressive features of the neoplasm and were

indicative of a hopeful prognosis. The hemoptyses in such cases are due to pulmonary deportation of villi or syncytial cell masses with transitory proliferation rather than true metastases. Removal of the primary focus, i. e., hysterectomy, should always be performed regardless of the seeming hopelessness of the situation.

Clinical Notes, Suggestions and New Instruments

PYOGENIC OSTEOMYELITIS OF THE SPINE, MEDIASTINAL ABSCESS AND COMPRESSION OF THE SPINAL CORD

NORMAN Q. BRILL, M.D., AND DAVID E. SILBERMAN, M.D., NEW YORK

We are reporting this case because of the rarity of the condition (only one similar case is recorded in the literature) and because it illustrates the proper therapeutic approach to osteomyelitis of the spine when it is complicated by mediastinal abscess and compression of the spinal cord.

REPORT OF CASE

S. S., a white boy, aged 17, was admitted to the Montefiore Hospital on May 27, 1937, with a diagnosis of active rheumatic fever. His past history included measles and a tonsillectomy in early childhood. In September 1936 a furuncle appeared on the right cheek, and he squeezed it. Three days later fever and a chill developed. The fever persisted, and after ten days there developed pain, swelling and limitation of motion in the left knee and the right elbow, which lasted three weeks. A diagnosis of rheumatic fever was made by the family physician and a consultant.

The patient was admitted to a hospital, where a heart murmur was allegedly found. After three weeks he returned home and experienced a recurrence of pain in his knee and a transient involvement of his right shoulder. In the middle of November there developed throughout the lower half of the chest a moderately sharp, intermittent and nonradiating pain, which persisted for several weeks.

In the latter part of December he had a severe, viselike, agonizing pain in the back, which radiated around both sides of the chest to the front and was brought on by the slightest motion of his body, even by the slight motion in breathing. This pain subsided after one week.

During all this time an irregular fever and tachycardia were present.

In January 1937 epigastric pain and anorexia occurred. At the same time the patient noted weakness of the left leg and spontaneous movements of both lower extremities. In February he noticed loss of sensation in the lower portion of the trunk and the right lower extremity. His condition remained unchanged until two weeks before his admission to the Montefiore Hospital, in May, at which time he complained of loss of sensation in the bladder, marked dysuria and difficulty in voiding.

On admission, he appeared chronically ill. His weight was 99 pounds (45 Kg.), his temperature 100 F. and his pulse rate 135. Examination gave negative results except for the neurologic observations. No heart murmur was detected.

There was weakness of both lower extremities, with bilateral Babinski signs and ankle clonus. In addition there was impairment of sensation to the level of the eighth dorsal segment. A neurologic consultant confirmed the bilateral signs referable to the pyramidal tract and found an irregular sensory level between the sixth and the ninth dorsal segment. A diagnosis of epidural abscess with compression of the spinal cord was made.

Examination of the blood revealed 75 per cent hemoglobin (Sahli), 4,700,000 red cells and 17,500 white cells, of which 74 per cent were polymorphonuclear. A blood culture and the Wassermann reaction were negative.

Lumbar puncture yielded clear fluid. The initial pressure was 160 mm. of water. There were poor rises on jugular

Fig. 1.—Anteroposterior view, showing the spindle-shaped mass in the mediastinum.

compression and delayed return to normal, indicative of partial block. The Pandy test showed a 3 plus reaction; there were 63 mg. of total protein per hundred cubic centimeters and 2 white cells per cubic millimeter.

Roentgenograms of the chest and the vertebral column showed a spindle-shaped mass in the mediastinum, adjacent to the spine (fig. 1), and partial absorption of the fifth and sixth dorsal vertebrae anteriorly (fig.

2). The diagnosis was modified to osteomyelitis of the vertebrae, with mediastinal abscess, and extension of the infection into the spinal canal, with compression of the spinal cord.

On June 4 a diagnostic aspiration was performed posteriorly in the fifth intercostal space, 2 inches to the right of the midline, and sanguineopurulent material was obtained. This showed *Staphylococcus aureus* on smear and culture.

On the following day the patient was operated on under general anesthesia. Portions of the fifth and sixth ribs were

removed paravertebrally on the right side, and a large abscess was incised and drained. The abscess cavity was in direct communication with the vertebral column.

At operation the patient suffered an accidental pneumothorax, and after a rather stormy postoperative course, during which pyopneumothorax developed, he began to improve. At the present time (October 1937) he is up and about and has gained 25 pounds (11 Kg.) since the time of his admission to the hospital, five months ago.

Fig. 2.—Lateral view, showing (a) the mediastinal mass, (b) the trachea displaced anteriorly and (c) partial destruction of the bodies of the fifth and sixth dorsal vertebrae.

A neurologic examination done six days postoperatively showed some return of sensation to the bladder and a moderate increase in the power of the lower extremities. There was slight improvement in sensation, and no Babinski sign could be elicited.

The temperature of the patient gradually fell to normal, and three weeks after the operation no sensory level was demonstrable.

At present there is still a residual hyperreflexia, with slight impairment of the vibratory sense in the lower extremities and minimal weakness of the left lower extremity. Spinal

fluid pressures are normal, and there is no evidence of block. There has been complete resorption of the pleural empyema (fig. 3), and the vertebrae show marked evidence of repair.

COMMENT

The illness probably began with transient bacteremia, secondary to the furuncle on the face. Metastatic involvement of the joints and the dorsal spine followed. There was extension from the latter into the mediastinum anteriorly, with abscess formation, resulting in the diffuse pain in the chest, and later posterior extension into the epidural space, with consequent severe root pain. Slowly progressive compression of the cord then ensued, due possibly either to pressure of frank pus or to the formation of chronic epidural granulation tissue or both. It may have been due to changes in the cord secondary to involvement of the vessels. Operative intervention through the mediastinum permitted drainage and relieved the compression, as was revealed by the neurologic status six days postoperatively.

Schwarz¹ reported a very similar case. A 5 year old girl had osteomyelitis of the vertebrae which ruptured posteriorly and became evident as an abscess of the back. After simple incision and drainage, slight meningeal signs developed. A laminectomy was performed, and pus drained from the epidural space. The dura was covered with granulation tissue. Another laminectomy was necessary at a lower level to permit adequate drainage. The patient did not improve, and it was only after an interval of two months, when x-ray examination revealed the presence of a mediastinal abscess, that a posterior rib resection was done and the abscess drained. The child then recovered. There was no evidence of compression of the cord in this case.

Fig. 3.—Anteroposterior view, showing complete disappearance of the mediastinal abscess. The evidence of the rib resection is apparent on the right.

In our case the decision to drain the abscess through the mediastinum was a fortunate one and resulted in rapid recovery. Had a laminectomy been performed to relieve the compression of the spinal cord, the result (as in Schwarz's case) would not have been as dramatic as it was and the condition might have terminated with fatal meningitis.

In 1904 Hunt² maintained that all acute epidural abscesses are secondary to osteomyelitis of the spine. This view has been accepted by several others but in general has not found wide favor. In July 1937 Browder and Meyers³ reported seven cases of epidural infection; a definite vertebral lesion was discovered in six and could not be excluded in the seventh. Our case is another which illustrates the fundamental relationship of osteomyelitis of the spine to epidural inflammations.

SUMMARY

In a case of osteomyelitis of the spine complicated by mediastinal abscess and epidural inflammation, with compression of the spinal cord, posterior rib resection resulted in adequate drainage of the mediastinal abscess and prompt relief of the compression and permitted healing of the osteomyelitis. In a case of this kind, a mediastinal approach is preferable to a laminectomy as a method of drainage.

ALLERGY TO ORAL ADMINISTRATION OF LIVER
CONCENTRATE

JOSEPH W. GARDNER, M.D., GLASGOW, MO.

In a recent issue of THE JOURNAL Cripp¹ recorded an instance of allergy to the injection of liver extract. I have recently observed a similar instance of allergic reaction to liver concentrates administered orally, which allergy had not been acquired from the previous administration of liver, and the reaction was accompanied by uterine bleeding. I have been unable to find any record of a similar instance; therefore, the following case would seem worthy of being recorded:

REPORT OF CASE

Mrs. L. W., a white woman aged 32, gave a history of regular menstruation every twenty-one days since the age of 12. Her periods had been interrupted only by two pregnancies, once in 1933 and again in 1936. She gave a history of allergic reaction to strawberries and any product containing sodium bicarbonate of any appreciable amount. She also suffered from ragweed hay fever in season.

Jan. 19, 1937, curettement and perineal and cervical repair were done for injuries received during labor in 1933. Physical examination was essentially negative except for lack of free hydrochloric acid in the stomach, which finding was associated with sporadic attacks of diarrhea that were controlled by taking diluted hydrochloric acid with her meals. The patient had an uneventful recovery from her operation and a month later consulted me because of weakness and a tired feeling. The red blood cell count was 4,000,000 and hemoglobin 80 per cent. Hence she was given lextron,² two capsules three times a day. Immediately after the administration of this liver concentrate she complained of severe weakness, dizziness and palpitation and was forced to go to bed. The following day she began to menstruate very profusely, and it was necessary to give her fluidextract of ergot, 1 drachm (4 cc.) every three hours; and elevate the foot of the bed to control the bleeding. She inquired at that time whether she was taking liver and stated that she had had a spell similar to the present one following the administration of jeculin,³ after the delivery of her first child, and that she continued to flow heavily until the jeculin was discontinued. I immediately discontinued the lextron and two days later the patient was able to get out of bed but was still weak and dizzy. May 4 I decided to find out whether her symptoms were coincidental or were an allergic response to the administration of the liver concentrate. During the months of March and April she had been quite regular in her periods. Thus, on the 4th of May she was given one capsule of lextron. The following day two capsules were given and she became weak and dizzy and complained of palpitation. The next day, after the administration of two more capsules of lextron, bleeding began with cramps, and the next day the uterine hemorrhage was very striking. Medication was discontinued but she continued to flow for two more days. May 12, regular menstruation began, lasting two days and requiring two pads daily. She had no bleeding then until the 16th, when she was given two capsules of extralin with a recurrence of all her symptoms and some spotting. Medication was discontinued and she had a normal menstrual period on May 31. On June 9 she was again given two capsules of extralin with the same symptoms as on the previous occasion. Since that time she has been given no more liver concentrate and her periods have been quite regular. After discontinuing the liver, the patient was given iron and ammonium citrate and numerous other iron preparations in capsule, tablet and liquid form and she suffered no untoward manifestations. None of the liver extracts were administered intramuscularly or intravenously.

I concluded that, since extralin contains liver-stomach concentrate, lextron contains in addition iron and ammonium citrate and extralin contains vitamins B₁ and G and liver-stomach

concentrate, and jeculin contains red bone marrow in addition to the ingredients of lextron but no stomach, the only ingredient common to the three products, each of which produced the allergic manifestations, was the liver extract, and the iron preparations were ruled out by trial.

HOSPITAL AIR CONDITIONING

C. P. YAGLOU, M.S.

BOSTON

Medical research and hospital experience in the past ten years have indicated the value of air conditioning as an aid in certain therapeutic procedures. The experience of nearly fifty institutions using air conditioning in one or more wards has been reviewed in a recent report¹ of the American Hospital Association.

In the present paper are outlined the objectives and special problems arising in the control of ward atmospheres, with special reference to operating rooms, post-operative wards, nurseries for premature infants, fever cabinets or rooms, allergen-free rooms and oxygen chambers, where air conditioning has proved of value.

AIR CONDITIONING OPERATING AND POST-
OPERATIVE ROOMS

The main objectives in air conditioning operating rooms are to reduce the risk of explosion of certain anesthetic gases and to protect the patient and operating personnel against extremes of heat or cold in summer or winter.

Explosion Hazard.—Ether and ethylene in themselves are not explosive, but they become explosive when mixed with air or oxygen in certain proportions.

TABLE 1.—Approximate Limits of Inflammability of Ethylene and of Ether
(After Coward and Jones,² Courtesy, U. S. Department of Commerce)

	Lower Limit %	Upper Limit %
Ethylene in air.....	3.0	30±
Ethylene in oxygen.....	3.0	80±
Ether in air.....	1.7	6 to 50
Ether in oxygen.....	1.7	40±
Ether in nitrous oxide.....	3.8	26±

In table 1 are shown the limits of inflammability of these two common anesthetics. Although the lower limits are fairly definite, the upper limits may vary considerably, depending on a number of factors.³

It is evident from table 1 that the most critical period is during the "washing out" process at the end of the operation, when the concentration is diluted to the explosion range. The most serious cause of accidents is static sparks in dry atmospheres,³ a factor that cannot be entirely eliminated by grounding the anesthesia apparatus because it is difficult to make the rubber parts conductive to electricity. By means of an

This is the fifth report of the committee established by the American Medical Association to study air conditioning. The committee includes Carey P. McCord, Detroit, chairman; Emery R. Hayhurst, Columbus, Ohio; William F. Petersen, Chicago; Horatio B. Williams, New York, and Constantin P. Yaglou, Boston.

electroscope, Herb⁴ has shown that grounding affects but a small section of the rubber and that segments an inch or two away retain their charge. The same probably holds true for woolen blankets and clothing.

The measures recommended by the Committee on Anesthesia Accidents of the American Medical Association⁵ are humidifying the air to 55 per cent relative humidity, grounding the operating table and apparatus and making the floor conductive to earth by the use of a large sheet of metal, so that everything, including the personnel, is kept grounded at all times. In new buildings "terrazzo" floors with grounded brass strips are often installed for this purpose.

Explosion may also result from a combination of oxygen with oil and grease and from several other circumstances which need not be gone into here. A high humidity in winter is advantageous not only from the standpoint of explosion but also from the beneficial effect it might have in reducing loss of fluid from exposed viscera and from the wet skin of the patient, and by permitting a lower room temperature. Humidifying apparatus and controls require constant supervision to guard against drops of humidity which might prove serious.

Desirable Air Conditions in Operating and Postoperative Rooms.—It has long been known that patients under the influence of anesthesia lose ability to regulate their own body temperature, but we still do not know much about the optimum range of air conditions that will keep the body temperature normal and in this way reduce the possibility of shock and some other postoperative complications.

Barbour and Bourne⁶ found that for etherized fasting dogs the optimum temperature was about 88 F. Below 88 the body temperature fell and the blood solids increased, while above 88 the body temperature rose gradually. Administration of fluids in sufficient amounts to offset the concentration of blood induced by ether lowered the body temperature, and an air temperature of about 91.5 F. was required to maintain at normal both body temperature and blood fluids. Humidity made little difference. Such high temperatures are unbearable for the operating personnel, and a compromise is often made by keeping the room between 72 and 80 F. in cold weather with the patient carefully protected with blankets and hot water bags during and for some time after the operation.

Postoperative Heat Stroke.—Postoperative complications are probably as serious with overheating as with underheating. About twenty-five years ago, Moschcowitz⁷ discovered that deaths after surgical operations were greater during summer heat waves than in cool weather and that in a number of cases the symptoms were identical with those of heat stroke. Since then, numerous other cases have been described in the literature by Botteselle,⁸ Walton,⁹ Martin,¹⁰ Everett and Whitham¹¹ and others. Patients apparently convalesc-

ing satisfactorily from operations suddenly became prostrated in hot weather with symptoms that were typical of heat stroke. In a number of instances, the heat stroke was verified at necropsy. Dehydration from excessive loss of water and blood is believed to have been an important factor in the production of heat stroke in many cases. Collier and Maddock¹² attempted to reduce excessive water loss by lowering the room temperature and by removing blankets from the patient, but these measures had no effect.

Cooling of operating and convalescent rooms in warm weather not only protects against heat stroke during the crucial period of recovery but also improves the recuperating power of the patient as well as the comfort and efficiency of the surgical staff. In warm weather the comfortable air conditions for the operators do not differ much from those of the patient, and a compromise is, as a rule, not difficult. With a relative humidity of about 55 per cent, a temperature of about 80 will probably prove acceptable. Additional heat may be applied to the patient locally or by suitable covering, according to body temperature in individual cases. In convalescent rooms the temperature may be lowered gradually to approach the normal ward temperature, and the humidity is relatively unimportant.

Air Conditioning Equipment.—Central station plants and individual room air conditioners have proved satisfactory in operating and postoperative rooms, furnishing between six and fifteen air changes per hour of filtered and suitably humidified air, with provision for cooling and removal of excess moisture in warm summer weather. The chief disadvantage of room conditioners is their noise. Recirculation of air is not used extensively in operating rooms partly because of odors and partly because of the more expensive spark-proof equipment necessary.

A high airflow in operating rooms is desirable for three reasons: (a) to reduce anesthetic concentration below the physiologic threshold in the vicinity of the operating team, (b) to remove excessive amounts of heat given off from sterilizing equipment if inside the operating room from the powerful surgical lights, from solar radiation on walls and glass and from the bodies of the operators and (c) to allow extra capacity for quick preparation for emergency operations. A separate exhaust system is often desirable in order to remove gases and odors at the source. Good insulation of sterilizing equipment and thorough exhaust ventilation of sterilizing rooms adjoining operating rooms will help in reducing considerably the capacity and running cost of the cooling equipment.

Sterilization of Air.—An important recent development is the sterilization of air of operating rooms and contagious wards by the use of ultraviolet lights.¹³ Hart¹⁴ believes that many operating room infections are air borne and that the hazard may be materially reduced by direct ultraviolet radiation over the operating table, with the operators protected from radiation by means of suitable gowns, masks, gloves and goggles. In about fifty operations with large incisions there have been no infected wounds, healing was more rapid, there was little rise in temperature, and postoperative pains were less severe.

AIR CONDITIONING NURSERIES FOR PRE-MATURE INFANTS

It has long been known that one of the most important requirements in the care of premature infants is the stabilization of body temperature, because their heat-regulatory mechanism is not fully developed. The usual means for controlling the body temperature are heated beds, electric incubators, hot water pads, and the like, but most of these have not entirely fulfilled the environmental needs of premature infants, owing to limited air space, inadequate ventilation, insufficient humidification in winter, and failure to provide for cooling and dehumidification in warm summer weather.

Optimum Air Conditions.—The effects of air conditions on the growth and development of premature infants have been studied in three air-conditioned nurseries at the Infants Hospital of Boston.¹⁵ Four criteria were used in establishing optimum conditions; viz., stability of body temperature, incidence and severity of digestive syndromes, gain in weight and mortality rate. Wide variations were found in the requirements for air temperature (from 75 to 100 F.) according to general constitution and body weight. The optimum relative humidity was placed at 65 per cent. The requirements in all cases consisted in providing (a) the lowest temperature that would stabilize body temperature, (b) a relative humidity of 65 per cent and (c) a ventilation rate between fifteen and twenty-five air changes per hour to maintain uniform temperature and humidity in extremes of weather and to eliminate objectionable odors which ordinarily are detected when one enters such nurseries.

Significant departures from these optimum air conditions exerted demonstrable harmful effects in these extremely sensitive reactors. When relative humidities between 25 and 50 per cent prevailed for two weeks or longer, the body temperature became unstable irrespective of air temperature, the incidence and severity of digestive syndromes increased, gains in weight diminished, and the mortality rose. On the other hand, air conditions with from 55 to 65 per cent relative humidity proved satisfactory over a period of years.

In table 2 are summarized the results of this study, including data obtained in the old nurseries prior to the installation of air-conditioning apparatus and in the conditioned nurseries with high and low humidities. All data shown are weighted averages and include all infants. Actually, the smallest infants benefited most by high humidities and the biggest least (see original report¹⁵). The benefits are attributed not only to improved air conditions but also to advances in medical and nursing care.

Suitable Methods for Air Conditioning Nurseries.—Most of the air-conditioning installations now in use for nurseries are of the central station type, providing for humidification and heating in cold weather and for cooling and dehumidification in warm weather with filtration and ventilation at all times.¹⁶ Compact unit air conditioners are available at reasonable cost for installation inside, or preferably outside, the nursery, owing to noise. There are also available now completely air-conditioned incubators, the merits of which remain to be tested. Recirculation is seldom used in these

wards, owing to odors and the possibility of cross infection. Improvements of methods for sterilizing air may permit partial recirculation with a significant reduction of initial and operating costs.

A single nursery conditioned to 77 F. temperature and 65 per cent relative humidity would fulfil the requirements of the majority of premature infants. Additional heat for weak infants may be furnished in the cribs, or by means of electric incubators placed inside the conditioned nursery, and the heat adjusted according to individual requirements. In this way the necessity for multiplicity of rooms and of air-conditioning units is obviated; the infants in the heated beds derive the benefit of breathing cool humid air, and the nurses and doctors need not expose themselves to extreme conditions.

AIR CONDITIONING IN ALLERGIC DISORDERS

Usefulness and Limitations.—The use of pollen-free air for relieving symptoms of hay fever and pollen asthma is credited to Storm Van Leeuwen.¹⁷ He obtained pure air from the top of a shaft 30 meters

high; he then cooled the air to -5°C . in order to condense out microdroplets and finally reheated it to a comfortable temperature in a specially constructed room where patients were exposed.

In the past ten years, various kinds of filters have been tried with results that are comparable to those secured by desensitization treatment, so long as the patients remained in a pollen-free atmosphere.¹⁸ Filtration and other air-conditioning methods will never replace medical treatment, because they are not preventive but give only temporary relief; the symptoms recur on exposure to pollen-laden air. Moreover, only extrinsic forms of allergy are benefited by air conditioning. Patients with bacterial asthma may not respond at all and the symptoms may even be aggravated by air conditioning.

Despite these limitations, air-conditioning methods have definite advantages in the simplicity and con-

venience of treatment. Hay fever patients are usually relieved of most of their symptoms within an hour's exposure to filtered air.¹⁹ Relief to patients with pollen asthma comes slower, depending on the severity of symptoms.²⁰

A pollen-free atmosphere is especially valuable when medical methods are not entirely successful or when desensitization is not advisable owing to concurrent illness. It offers a good means for diagnosing sensitivity, as the failure of the asthmatic to obtain relief in such a room would exclude pollens as the cause.²¹

Nonseasonal asthma is sometimes attributed to sensitization to house or street dust,²² odors and irritating gases²³ or to any stimulus capable of exciting the vagus system of allergic individuals to activity.²⁴

Suitable Air Conditions.—Although the chief remedial factor in the treatment by conditioned air appears to be filtration of pollens, there is considerable evidence that heat or cold, direct drafts, and particularly sudden temperature changes are important in initiating or aggravating asthmatic attacks.²⁵ It is often stated in the literature that heat regulation in asthmatic individuals is likely to be unstable, with a tendency to hypothermia. Humidity may benefit a few²⁶ but aggravates the condition in the majority of cases.²⁷

In the experience of Rappaport, Nelson and Welker,²⁸ temperatures between 76 and 82 F. in warm weather with relative humidities about 30 per cent were found more comfortable to patients than lower temperatures with high humidities. Still uninvestigated is the connection between thunderstorms and attacks of pollen asthma in symptom-free patients who lived in a pollen-free and comfortable atmosphere. Changes of barometric pressure or ionization are suspected but not as yet proved.²⁹

Methods of Filtering Pollens from the Air.—Paper and cloth filters of suitable area proved quite satisfactory in removing all but traces of pollens (from 95 to 99 per cent). Allergens may also be removed by electro-

static precipitation³⁰ and by passing the air through a suitable water spray, or over cooling coils kept at a temperature low enough to cause precipitation of nuclei on the surface of the coils.

Inexpensive filter units are now available for home or office use, with or without cooling. In the simplest type, which fits in the window like an extension screen, outdoor air is drawn in by means of a small fan and passed through a fine cloth filter before diffusing into the room. All other windows in the room are kept shut. There are also masks which fit tightly over the nose and mouth and in this way remove pollens from the inspired air. For best results, some method of cooling and dehumidification is desirable in warm weather.

AIR CONDITIONING IN FEVER THERAPY

The therapeutic possibilities of artificial fever have been reviewed recently by Hench,³¹ Desjardins,³²

Fig. 1.—The Kettering hypertherm (Courtesy Walter M. Simpson, M.D., Miami Valley Hospital, Dayton, Ohio).

Metz,³³ Bierman³⁴ and others. Many diseases have been treated, in the past four years, with various degrees of success. The greatest field appears to be in the treatment of acute and chronic gonorrhea, since the specific pathogenic organisms involved can be killed by heat³⁵ within the limits of tolerance of man (from 105 to 107 F.). Lately, fever therapy has appeared to be of value in the management of painful neuritic states in

which heretofore no single procedure has given satisfactory relief. Bennett and Cash³⁵ present extensive clinical evidence on the relief of painful neuritic meningitic and radicular states with systemic fever at 103-105 F. in treatments of two to three hours each, from two to six treatments altogether.

Since 1918, when Wagner von Jauregg introduced malaria therapy as a means of producing artificial fever, various other methods have been tried, including injection of vaccines, colloid or crystalloid substances, and various physical means, such as hot baths, radiant heat, diathermy, radiotherapy, heat blankets and air-conditioned cabinets. The relative advantages and limitations of these methods were recently discussed by Doub³⁶ and by Desjardins, Stuhler and Popp.³¹ Although comparable results may be obtained with most of these methods, the air-conditioned cabinets are believed to offer a safer and more effective means, by permitting more accurate control of temperature and by reducing the hazards inherent to certain other methods. Some workers have secured better results by combining systemic fever with chemotherapy or with additional local heating by diathermy or other means than by the use of heat cabinets alone.

Simpson³⁷ described the first practical heat cabinet for hospital use, known as the "Kettering hypertherm." Briefly, it consists of an insulated cabinet about 6 feet long, 3 feet wide and 2½ feet high, equipped with electric heating and humidifying apparatus. Hot air at from 130 to 150 F. and from 30 to 50 per cent relative humidity is circulated to the patient's compartment at the rate of 425 cubic feet per minute by means of a centrifugal fan. The temperature and humidity are automatically controlled by the setting of a knob and their values are indicated conspicuously on large dials with warning pilot lights on the front end of the cabinet. The nude patient lies on an air mattress with his head protruding outside the front end of the cabinet through a rubber collar (fig. 1). Any degree of fever can be induced quickly or slowly and maintained as long as desired according to individual requirements. Simpson finds that the body temperature rises to 105 F. in forty to sixty minutes. Water and chlorides lost in the sweat are replaced by mouth during the treatment.

In the past three years, several heat cabinets have appeared with some improvements. Probably the most important improvement is the substitution for hot dry air of nearly saturated air at a comparatively low temperature. In this way burns of the skin are eliminated, the loss of water and chloride may be less,³⁸ and the room in which the hypertherm is located is not heated as much as when hot dry air is used.

It can be seen in figure 2 that with a relative humidity of 30 per cent it would take too long to raise the body temperature 6 degrees F. (from 99 to 105) without resorting to excessively high air temperatures. With 60 per cent relative humidity and air movement of 400 feet per minute over the body, a temperature of about 120 F. will raise the body temperature 6 degrees in one hour, whereas with saturated air the cabinet temperature need only be from 106 to 107 F. These values will vary in different individuals and in different diseases.

Few data are available on the combinations of temperature and humidity required to maintain the body at various fever temperatures after initial heating. With saturated air a temperature of about 100 F. appears to be sufficient to keep the body at 105.

Extensive work in fever therapy is continuing on a wide variety of pathologic conditions. While this form of therapy is rapidly gaining wide recognition, its application, according to the American Medical Association, "should remain strictly a hospital procedure surrounded with the safeguards commonly employed in a major operation and under the direction of skilled physicians." The dangers associated with fever therapy were disclosed in recent papers by Kopp and Solomon,³⁹ Hartman⁴⁰ and others.

AIR CONDITIONING IN OXYGEN THERAPY

Excellent reviews of the underlying physiologic principles of oxygen therapy and its value in various diseases have been written recently by Boothby,⁴¹ Potts⁴² and Barach.⁴³

Fig. 2.—Rise of body temperature (rectal) in a group of normal men after one hour's exposure in an air-conditioned room (after McConnell, W. J., and Yaglou, C. P.: Air Motion, High Temperatures and Various Humidities: Reaction on Human Beings, Tr. Am. Soc. Heating and Ventilating Engineers 30: 167, 1924; courtesy American Society of Heating and Ventilating Engineers).

Oxygen Tents.—In oxygen tents, or chambers, air conditioning is concerned with the conservation of expensive oxygen gas by removal of excessive heat, moisture and carbon dioxide, in a closed space in which there is no outside air supply other than that from leakage.

In tents, the cooling medium is usually ice. A small motor blower circulates the air over soda lime to remove carbon dioxide and then over ice for cooling and dehydration. The concentration of oxygen is regulated by means of a pressure-reducing valve and flowmeter. The usual rate of flow is from 5 to 10 liters per minute in tight tents, and the usual oxygen concentration is

50 per cent or less. Temperatures down to 75 F. and humidities between 40 and 50 per cent are approximately the limits of the equipment in warm weather.

Oxygen Chambers.—Oxygen chambers were introduced by Barcroft, Hunt and Dufton⁴⁴ in England and by Stadie⁴⁵ and Binger⁴⁶ in America. The conventional chamber is made of sheet steel and is large enough to accommodate one or two beds. All entrances

Fig. 3.—Line drawing of a conventional oxygen chamber with gravity air circulation.

are provided with trap doors to avoid loss of oxygen. Illumination comes through a glass window in the ceiling. The conditioning system is either the gravity type first used by Barach⁴⁷ or the fan type using silica gel and mechanical refrigeration. Circulation in the gravity type is induced by means of a heating coil and a cooling coil on opposite walls (fig. 3), the former regulating the temperature, and the latter the humidity with automatic controls. Soda lime at the bottom of the cooling coils removes excessive carbon dioxide. The main objections to gravity circulation are stratification of cold air near the floor and accumulation of odors.

In the fan-circulation system (fig. 4) moisture is absorbed in silica-gel beds and the air is cooled by compact finned coils through which cold brine is circulated. Spray dehumidifiers are unsuitable for this purpose because the air must be cooled often below 32 F. in order to obtain relative humidities well below 30 per cent, for the treatment of pneumonias and bronchial conditions.

The factors which determine the selection of proper temperature and humidity in oxygen therapy are primarily individual; the patient rather than the disease is given first consideration. For pneumonias, Bullowa⁴⁸ and Barach⁴⁹ place the desirable temperature range between 60 and 75 F., with relative humidities between 20 and 50 per cent. The consensus favors as low a humidity as is consistent with economy.

Oxygen chambers are more comfortable than oxygen tents, particularly to the restless and delirious types of patients. Nursing and medical care is unhampered and oxygen concentration, temperature and humidity can be accurately controlled at any desired level.

The main disadvantage is high initial and operating costs in comparison with tents and other simpler methods. The cost may be justified in large hospitals

and for research purposes, but for routine oxygen therapy alone conventional metal chambers have proved to be a liability rather than an asset, because they are not used continuously and cannot be used for anything else.

There is no reason why an ordinary room cannot be made fireproof and reasonably airtight without expensive metal construction. In addition to pneumonias and respiratory and heart disorders, many diseases affected by heat, cold, humidity or chemical constitution can be taken care of in one or two such rooms without serious difficulties in the design of air-conditioning apparatus. The rooms can also be used as ordinary wards with or without running the conditioning apparatus, when they are not needed for special treatment.

GENERAL HOSPITAL AIR CONDITIONING

Complete conditioning of large hospitals is much too expensive in initial and operating costs to be justified on the basis of any available evidence.

In the cold season of the year, the requirements of almost all general and private wards can be satisfactorily fulfilled by rational heating in conjunction with window ventilation and gravity or mechanical exhaust. Insulation for heat and sound is very important. Excessive outside dust and noise may be controlled by the use of suitable air filters and silencers in the window openings. The preferred method of heating is by hot water with radiators under the windows extending the entire length of the window. The preferred exhaust system in large buildings consists of one or more fans installed in the attic or in a penthouse on the roof. One or more vertical shafts connect the fan or fans with trunk ducts on the ceiling of each floor, and the exhaust openings in individual rooms communicate with these trunk ducts.

Cooling in warm weather deserves serious consideration, particularly in the South and Middle West. High cost precludes cooling the entire hospital, but the needs

Fig. 4.—A one-patient oxygen chamber of the fan-circulation type, using silica gel for dehydration (courtesy Silica Gel Corporation).

of the average hospital may be satisfactorily fulfilled by the use of built-in room coolers in certain sections of the hospital and a few portable units which can be wheeled from ward to ward when needed. In the past few years, these units have been improved so that they are now less noisy, easier to move and less costly. From the standpoint of noise and cost there are definite advantages in multiple built-in units furnished with refrigerant from one or more central compressors in the basement.

49. Barach, A. L.: A New Type of Oxygen Chamber, *J. Clin. Investigation* 2: 463 (Aug. 20) 1926.

Cooling in warm weather is of great value in maternity and delivery rooms, children's wards, x-ray rooms, and in the treatment of fevers, heat stroke, heart failure, enteric disorders and a number of other ailments that accompany summer heat waves.

A more thorough description of air-conditioning apparatus for hospitals, including initial and operating costs, is given in a Report of the American Hospital Association.⁵⁰

The operation of hospital air-conditioning plants is as important as the installation. Unless they are kept clean and are serviced periodically by competent engineers, they will not prove satisfactory in the hands of inexperienced hospital engineers.

55 Shattuck Street.

Council on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED.

FRANKLIN C. BING, Secretary.

SWISS BRAND EVAPORATED MILK

Manufacturer.—Ewing-Von Allmen Dairy Company, Louisville, Ky.

Description.—Canned, unsweetened, evaporated milk.

Manufacture.—Carefully selected milk is collected, shipped to the main plant in insulated tank trucks, pumped into storage tanks, cooled to 40 degrees, preheated, and held at 95 to 99 C. for thirty minutes. The milk is partially evaporated under vacuum, homogenized, standardized, cooled, filled into cans and sterilized.

Analysis (submitted by manufacturer).—Moisture 74.1%, total solids 25.9%, ash 1.5%, fat (ether extract) 7.9%, protein (N × 6.38) 7.3%, lactose (by difference) 9.2%.

Calories.—1.4 per gram; 40 per ounce.

DROMEDARY BAKED APPLES

Manufacturer.—Hills Brothers Company, New York.

Description.—Canned baked apples packed in syrup of granulated cane sugar, water and honey.

Manufacture.—Carefully selected and graded York Imperial apples are cored and the skin punctured by machine, again inspected and any remaining core, seeds and blemishes removed. The apples are washed, baked for forty-five minutes, placed in individual waxed paper cups, packed in tins, covered with hot syrup, sealed, processed and cooled.

Analysis (submitted by manufacturer).—Moisture 67.1%, total solids 32.9%, ash 0.3%, fat (ether extract) 0.4%, protein (N × 6.25) 0.7%, crude fiber 0.7%, carbohydrates other than crude fiber (by difference) 30.8%, sucrose 2.4%, reducing sugars as dextrose 28.8%.

Calories.—1.3 per gram; 37 per ounce.

NUTRADIET BRAND WHOLE RED BEETS PACKED IN WATER

Distributor.—The Nutradiet Company, a subsidiary of S & W Fine Foods, Inc., San Francisco.

Description.—Canned whole beets, packed in water without added sugar or salt.

Manufacture.—Properly matured Detroit Dark Red Beets are graded and stored for one to three days to set the color, are

inspected and hand topped, blanched, mechanically peeled in a stream of water, graded and packed by hand in enamel-lined tins. Boiling water is added and the containers are exhausted, sealed and processed.

Analysis (submitted by manufacturer).—Moisture 81.7%, total solids 18.3%, ash 0.5%, fat (ether extract) 0.1%, protein (N × 6.25) 0.7%, crude fiber 0.5%, carbohydrates other than crude fiber (by difference) 16.5%.

Calories.—0.70 per gram; 20 per ounce.

Claims of Manufacturer.—For use in special diets in which sugar or salt is proscribed or in quantitative diets of calculated composition.

ANDERSON'S WHEAT GERM

Distributor.—Mrs. Catherine S. Anderson, Grosse Pointe, Mich.

Manufacturer.—Pillsbury Flour Mills Company, Minneapolis.

Description.—Wheat embryo as obtained from the milling of hard wheat.

Manufacture.—Select hard red spring and hard red winter wheat are cleaned, scoured, tempered and milled by essentially the same procedure as described in THE JOURNAL, June 18, 1932, page 2210. The germ is separated from the first break middlings, flaked on suitable rolls, freed from impurities on a special sifter and packed by hand. The Pillsbury Laboratory reports that the finished product is composed of about 85 per cent germ, 10 per cent bran and 5 per cent endosperm.

Analysis (submitted by manufacturer).—Moisture 6.0%, total solids 94.0%, ash 4.5%, fat (ether extract) 12.3%, protein (N × 5.7) 30.6%, sucrose 16.3%, reducing sugar as dextrose 1.2%, crude fiber 2.5%, carbohydrates other than crude fiber (by difference) 44.1%.

Calories.—4.1 per gram; 116 per ounce.

Vitamins.—Reports of assays show 3,600 International units (4,788 Sherman units) of vitamin B₁ per pound and 1,816 Bourquin-Sherman units of vitamin G per pound.

LARSEN'S BRAND STRAINED APPLES AND APRICOTS

Manufacturer.—The Larsen Company, Green Bay, Wis.

Description.—Canned, sieved apples and apricots.

Manufacture.—Selected fresh apples are cored, chopped and combined with canned fresh apricots, mixed, softened, double screened under vacuum, and filled into cans which are sealed in vacuum and processed for sixty minutes at 212 F.

Analysis (submitted by manufacturer).—Moisture 81.7%, total solids 18.3%, ash 0.6%, fat (ether extract) 0.2%, protein (N × 6.25) 0.8%, crude fiber 0.7%, carbohydrates other than crude fiber (by difference) 16.0%, calcium (Ca) 0.013%, phosphorus (P) 0.055%, iron (Fe) 0.0012%, ratio calcium/phosphorus 0.24%, ratio carbohydrates/protein 20%.

Calories.—0.7 per gram; 20 per ounce.

MRS. PALEY'S BABY FOOD— STRAINED APRICOTS

Manufacturer.—Paley-Sachs Food Company, Houston, Texas.

Description.—Cooked, sieved, sulfured dried apricots, packed with added dextrose.

Manufacture.—Dried, sulfured apricots are washed, soaked for twelve hours, pressure cooked with added dextrose, sieved, filled into glass jars, vacuum sealed and heat processed.

Analysis (submitted by manufacturer).—Moisture 70.4%, total solids 29.6%, ash 1.1%, fat (ether extract) 0.1%, protein (N × 6.25) 1.1%, reducing sugars as dextrose 10.3%, sucrose 10.8%, crude fiber 0.9%, total carbohydrates other than crude fiber (by difference) 26.4%, calcium (Ca) 0.024%, phosphorus (P) 0.048%, iron (Fe) 0.0023%, sulfur dioxide (SO₂) 0.0211%.

Calories.—1.1 per gram; 31 per ounce.

THE LYMPHATIC SYSTEM

In his Harvey lecture, last year, C. K. Drinker¹ of the Harvard School of Public Health reviewed our knowledge of the functional significance of the lymphatic system. Of all mammals man can probably claim the most extensive and elaborate lymphatic apparatus. One of the principal functions of this system is defense against inflammatory processes, but this is not the whole story. The study of lymphatic function under normal conditions has already yielded information of additional import. The lymphatics are a simple subsidiary circulatory mechanism and are steadily engaged in moving fluid which leaves the blood capillaries and returns again to the blood. In a series of experiments begun in 1930 in Professor Krogh's laboratory, lymph was collected from different regions in the dog. The most dependable figure on the amounts of lymph collectable per minute (exclusive of the thoracic duct and abdominal vessels) were obtained by cannulating the lymph in the foreleg of a dog under local anesthesia. Fluid equal to fifty times the total blood plasma may leave the capillaries and pass through the lymphatic system in twenty-four hours. Furthermore, it was found from analysis of the chemical and physical properties that lymph is essentially a reflection of the composition of the blood plasma after allowance for dilution. In the light of modern experiment, therefore, it appears that in mammals such blood proteins as leave the capillaries to enter the tissue fluid are removed by the lymphatics. Under normal circumstances this function is called into play by such factors as changes in position, movement and tissue pressure. The composition of lymph is due to the filtration of products from the blood and not, as has been suggested, to the universal production of this fluid in the tissues.

Further information on the functions of this system was obtained by Drinker and his co-workers in a series of ingenious experiments begun in 1932. These were based on the ablation of lymphatic function in a part.

The conclusions as to what is normal were dependent on what failed to happen when such lymphatics were rendered functionless. Repeated centrally directed injections of a suspension of finely divided crystalline silica in 2.5 per cent quinine hydrochloride were used. In this mixture the quinine caused a painless necrosis of the tissues and the silica induced progressive fibrosis. In this manner lymphedema was produced, followed by fibrosis, overgrowth, typically elephantiac change and eventually epithelial proliferation in the foot pads. The second definite result was the appearance of an astonishing susceptibility to streptococcic infections. In addition to these factors, the isolated limb subject to experiment at once began to grow and the growth was wholly at the site of fluid accumulation; that is, in the skin and subcutaneous tissues. The tissue fluid gained steadily in protein until concentrations as high as 5 per cent were reached. These regions became for the first time susceptible to infection not only with the streptococcus but with other organisms as well.

Drinker believes that the lymphatic system retains its primitive position as part of the circulatory apparatus. Because the permeability of peripheral blood capillaries to protein is not quantitatively great, this function is overlooked until lymph drainage becomes important in the presence of spreading infection, edema or elephantiasis.

Lymph nodes represent a portion of the lymphatic apparatus that is particularly puzzling. They are effective filters; it is questionable whether any extravascular protein can get back to the blood vessels without going through a lymph node. Lymph flowing to a node from a number of afferent vessels reaches the marginal sinus and is there in a relatively large umbrella-shaped lake where the rate of flow becomes exceedingly slow and opportunity for settling occurs. This mechanical effect is supplemented by the biologic actions of endothelial phagocytes in the lymph node reticulum. These two effects are particularly well devised for impeding bacterial growth and spread. Therefore, even relatively huge doses of organisms entering through the afferent lymphatics escape from the node with difficulty if at all. If the infection is so overwhelming, however, that actual lymph node infection is established, the node may act as a nidus to feed organisms steadily into the lymph stream.

Another function of the nodes is to pour lymphocytes into the lymph stream, and this activity can be augmented by massage of a node.

Slowly the increasing availability of direct methods of experiment on this interesting system is adding to the sum of physiologic knowledge. The experimental methods available today indicate that this circulatory system will be slowly taken to pieces physiologically and analyzed just as has been the case with the blood circulatory system.

COLLAPSE THERAPY FOR PULMONARY TUBERCULOSIS IN OLDER PATIENTS

Collapse therapy for pulmonary tuberculosis has become, in the last two decades, a most important measure in combating this disease. Various methods of accomplishing collapse of the lung, as well as the indications for each, have been established. With the improvement in the technic and in the results obtained, the indications have widened to include a greater number of cases. Although collapse of the lung was at first considered suitable only for unilateral cases, it is now regarded as applicable under certain conditions to bilateral cases as well.

Decker,¹ in a recent communication, raises the question of the age limit, more specifically, the question of the benefits to be gained from surgical procedures in patients past 40 years of age. He presents an analysis of a group of patients whose ages ranged between 40 and 60 years. About 25 per cent of the cases were moderately advanced and the remainder far advanced. About half of the patients had bilateral lesions. Cavities were present in 106 (69 per cent). Here was a group of patients largely incapacitated for work, dependent on their families or institutions for support, and with no other outlook than invalidism and death from the disease. They were submitted to various forms of collapse therapy. The clinical results observed for periods ranging from six months to ten years suggest that about 20 per cent of this group will ultimately be well, perhaps able to do some work, that 25 per cent will be improved, that 25 per cent will remain unimproved and will die of the disease, and that 30 per cent have already died or soon will die. A comparison with the results in the age group of 20 to 40 years, according to Decker, showed a difference of from 10 to 15 per cent in less favorable response.

The least violent of the surgical methods, namely, artificial pneumothorax, was much less satisfactory in its effects than might have been expected. The method was tried in seventy-eight cases and the treatment was continued for periods of from three months to six years. It was carried to completion in 20 per cent and was discontinued because of unsatisfactory collapse in 15 per cent and for other reasons in 35 per cent. Arrest was obtained in 16.6 per cent, improvement in 24.5 per cent, no benefit in 32 per cent and mortality in 26.9 per cent. The failure to induce a sufficient degree of collapse in these cases is due to the greater frequency of adhesive pleuritis. The most satisfactory results were obtained with phrenic nerve exeresis. Of the seventy-three operations performed, eighteen resulted in arrest and thirty-three in improvement. Fixation of the diaphragm was obtained in all. Cavities were

closed in 15 per cent. Results with thoracoplasty were anything but encouraging. Of seventeen patients submitted to thirty-four operations, eight, or 47.2 per cent, died. Among the contributing causes the author considers the lowered vitality, extensive pleural adhesions, fibrosis and emphysema in the contralateral lung, arterial sclerosis, greater tendency to postoperative nephritis and beginning degenerative changes in the myocardium.

Because of the generally hopeless outlook of this group, they should be given whatever benefit they may derive from collapse therapy. Apparently indications for thoracoplasty must be even more strictly limited rather than extended.

CIRCULATION OF BILE AND SYNTHESIS OF HEMOGLOBIN

A continuous cycle of secretion and absorption of bile from the intestinal tract is apparently necessary for normal synthesis of hemoglobin. This conclusion by Hawkins and his co-workers¹ of the Department of Pathology, University of Rochester School of Medicine, is drawn from a continuation of their studies of experimental bile fistula in dogs. By the fistulas which they establish the bile is drained into the right renal pelvis. From earlier studies they found that exclusion of bile from the intestinal tract by this technic led to several abnormalities. First was the development of general osteoporosis, often leading to spontaneous fractures. Physiologic analysis showed that this abnormality of bone was caused by lack of absorption of vitamin D from the intestinal tract. The lesion in bone could be prevented by the oral administration of bile. A second abnormality of major importance was a tendency to purpura; often leading to spontaneous bleedings. Analysis showed that this bleeding was due to lack of prothrombin in the blood plasma. Here also the lesion could be prevented by adequate feeding of bile.

In order to study the effects of bile fistula on the formation of blood pigment the Rochester pathologists combined experimental bile fistula with experimental anemia. The anemia was produced by repeated withdrawals of relatively large amounts of blood. In the anemic dogs with bile fistula the rate of hemoglobin regeneration was but about half that in their control anemic dogs with normal circulation of bile. Iron given by mouth was utilized at but half the rate of its utilization in control anemic dogs. Colloidal iron injected intravenously, however, was therapeutically effective in both groups. Apparently dogs with bile fistula are able to absorb iron from the intestinal tract at only about half the normal rate. Unlike the reduced

1. Hawkins, W. R.; Robschit-Robbins, F. S., and Whipple, G. H.: *J. Exper. Med.* 67: 89 (Jan.) 1938. Hawkins, W. B., and Whipple, G. H., *ibid.* 62: 599 (Oct.) 1935. Hawkins, W. B., and Brinkhous, K. M., *ibid.* 63: 795 (June) 1936.

absorption of vitamin D, however, the rate of iron absorption could not be increased by the oral administration of bile.

The fact that dogs with bile fistula can be maintained at a normal body weight over a period of years indicates adequate absorption of protein digestive products. The failure of oral administration of bile to compensate for this reduced absorption of iron seems to suggest the existence of labile hormones or enzymes in freshly secreted bile. Perhaps this "ferrosynthesin" is destroyed or denatured by routine methods of preparation and oral administration of bile. Such a hypothetic enzyme might conceivably be necessary not only for adequate absorption of iron from the intestinal tract but after absorption as a hepatic stimulant or chemical precursor in synthesis of hemoglobin. The Rochester pathologists, however, wisely refrain from all theoretic speculations of this type and limit themselves to modest conclusions: (1) that a constant secretion and absorption of bile from the intestinal tract is necessary for a normal rate of iron metabolism, and (2) that lack of adequate bile circulation cannot be compensated for by the oral administration of bile. Iron given by mouth is only partially effective.

SCARLET FEVER QUARANTINE

From two state boards of health come announcements indicating changes in the quarantine regulations for scarlet fever. The Oregon State Board of Health¹ promulgates a modification of scarlet fever quarantine, with the statement that it "has found it necessary to require more rigid measures to prevent this disease from spreading."

At the same time the Iowa State Department of Health² announces a liberalization of quarantine to the extent of permitting the breadwinner to enter and leave a quarantined home in which there is a case of scarlet fever "provided he is not a food handler, does not come in contact with the patient or with groups of children and gives satisfactory evidence of immunity to the disease. However, if he handles dairy products or ready-to-eat foods, the breadwinner or other adult should live elsewhere while the home is placarded and not resume employment until from three to seven days after last exposure. This arrangement also applies to teachers and others who come in contact with children."

Here are two diametrically opposite actions, each taken by a state health organization of competence and experience.

The Oregon State Board of Health permits release after twenty-one days from the time when the case

has been reported, provided there are no evidences of infectiousness and provided negative cultures of the nose and throat have been obtained. According to the Iowa announcement, the minimum period of isolation is also twenty-one days, but in this case "from the day of onset of illness." As to cultures of the nose and throat, the Iowa announcement states, "in some instances it may be advisable for a public health laboratory to report on the presence or absence of the scarlet fever germ."

Since the adoption of modern methods of control of contagious disease, scarlet fever has created the most vexing problems in epidemiology which confront the physician and the public health officials. The difficulty begins with diagnosis; many atypical cases without rash or sore throat, of doubtful type, and strawberry tongues without diagnostic significance add to the difficulties of recognition. The missed and mild cases and healthy carriers are undoubtedly responsible for epidemics more than is the frank case of the disease, especially if the patient is severely ill. Once quarantine has been established, the question of termination is immediately raised. Quarantine periods have ranged all the way from a minimum of twenty-one days to a minimum of forty-two days, with twenty-eight days a common intermediate figure. The utmost difficulty is always experienced in persuading quarantined persons that the number of days is a minimum and not a maximum. In mild cases in which apparent recovery may take place as early as the seventh or tenth day, or in extremely mild cases in which the child is scarcely ill, the utmost resistance is encountered to a minimum of even twenty-one days. The culturing of throats for hemolytic streptococci is less satisfactory than culturing for diphtheroid organisms because of the difficulties inherent in distinguishing the strains of the hemolytic streptococcus, and the absence of a relatively easy virulence test to settle problems of prolonged quarantine. If the health officer liberalizes quarantine and an outbreak follows, he may erroneously be blamed for what was in no way related to the official action. If he tightens his regulations to assist in the control of a threatened outbreak, he is faced with the problem of evasions and nonreporting.

Scarlet fever has apparently grown milder, if one may judge by reported death rates. This may be a reflection of modern hospital and nursing care, of such immunization as has been done, and of the use of serum therapy in severe cases. It may, however, be due merely to a zymotic cycle. The problem of scarlet fever is far from solved. What is needed more than anything else is a laboratory technic for the quick and inexpensive diagnostic culturing of hemolytic streptococci of the scarlet fever strains, and extensive observations in the field to observe the effects of release on the basis of negative cultures.

Current Comment

DISTRIBUTION OF HOSPITAL SERVICE

In the United States there are only five counties with a population density of five per square mile within thirty miles of which there is no registered general hospital. As vast programs of hospital construction are being advocated,¹ certain facts regarding the present distribution of hospital facilities should be kept in mind. In 1937 there were 6,128 hospitals registered by the American Medical Association with a capacity of more than a million beds and fifty-five thousand bassinets, to which well over nine million patients were admitted during the year.² True there are 941 counties without a registered hospital, but of these, 560, or 60 per cent, lie wholly within a thirty mile radius of hospitals in adjoining territory. There remain 368 counties parts of which are within thirty miles of existing hospital facilities and, in the whole country, but thirteen counties no part of which is within thirty miles of a registered general hospital. The population of these counties is 67,800. Eight of them support less than five persons per square mile. There may be some localities in which hospital facilities are needed. However, the Commonwealth Fund, which for the past ten years has been awarding hospitals to communities which seemed to be able to maintain such institutions with proper standards, has thus far made eleven awards.

RISK IN USING ZINC SULFATE FOR PREVENTION OF POLIOMYELITIS

About one year has passed since Schultz and Gebhardt reported that 1 per cent zinc sulfate solution applied to the olfactory mucosa in monkeys affords a high degree of protection against poliomyelitis virus instilled into the nose a month later. This method of prevention has been used experimentally in many places. The risk of producing permanent loss of the sense of smell must be considered in connection with its use. Schultz and Gebhardt (page 2024, this issue), point out that several cases have occurred in which the sense of smell has not yet returned after a period of more than six months. Cases of such lasting anosmia have not been discovered in children, however, perhaps because of anatomic differences in the nose. Schultz and Gebhardt recently observed after the application of zinc sulfate to the olfactory area of monkeys a severe exudative inflammation of the olfactory mucosa, together with desquamation of epithelial cells. Caution is advised, therefore, in the further use of zinc sulfate in man until more is known about the risk of permanent anosmia and of the mechanism underlying the protection against poliomyelitis in monkeys. The full answer to this problem cannot be obtained from experimental work on animals. Physicians will be able to help investigators by transmitting to them their individual experiences.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST; SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Symposium on Oxygen Therapy.—The Jefferson County Medical Society sponsored a symposium on oxygen therapy at a meeting in Birmingham May 16. The speakers-included:

Allen D. Keller, Ph.D., professor of physiology and pharmacology, University of Alabama School of Medicine, Physiology of Oxygen Want.
J. I. Banash, B.S., consulting engineer, Chicago, Mechanical Considerations of Oxygen Therapy Apparatus.
Dr. James S. McLester, professor of medicine, University of Alabama School of Medicine, Clinical Response to Oxygen Therapy.

CALIFORNIA

Plague Infection in Squirrels.—According to *Public Health Reports*, plague infection has been proved by animal inoculation in one beecheyi squirrel from a ranch four miles east of Watsonville and in a pooled specimen of organs from five squirrels from a ranch six miles east of Watsonville, Santa Cruz County. These specimens were submitted to the Hooper Foundation for Medical Research, San Francisco, April 13.

Changes Among Health Officers.—Dr. Ellis D. Sox, Berkeley, has been appointed health officer of Tulare County; the unit has recently been placed on a full time basis. Dr. Elmo R. Zumwalt, Tulare, health officer of the unit under the old setup, continued on a part time basis until June 1. Dr. Elmer M. Bingham, San Luis Obispo, health officer of Yolo County, has been appointed to a similar position in San Luis Obispo County. He succeeds Dr. Allen F. Gillihan, who retired on account of ill health. Dr. John O. Rafferty, Oakland, has been appointed to succeed Dr. Elmer McK. Bingham, San Luis Obispo, as health officer of Yolo County. Dr. Seth H. Miles, Santa Monica, has been appointed health officer of Mono County, succeeding Dr. Robert K. Harker, Bridgeport.

CONNECTICUT

Society News.—The New Haven Medical Association was addressed April 20 by Dr. Arthur Krida, New York, on "Treatment of Fracture of the Hip."—At a meeting of the Yale Medical Society in New Haven May 11 the speakers were, among others, Abraham White, Ph.D., on "Chemical Studies of Anterior Pituitary Hormones" and Dr. Hebbel E. Hoff and Richard G. Horton, Ph.D., "Cortical Control of Cardiovascular Reflexes." A special meeting of the society was addressed May 18 at the Sterling Hall of Medicine by Dr. Herbert W. Wade, medical director, Leonard Wood Memorial, Culion, P. I., on "Leprosy as a World Problem." Dr. Wilder G. Penfield, Montreal, discussed "Circulatory Changes in the Epileptic Brain" before the society April 13.

Thirty Years of Mental Hygiene.—The Connecticut Society for Mental Hygiene observed its thirtieth anniversary at a two day celebration May 6-7 in New Haven. A founders' dinner commemorated the event May 5. Other features included a public jubilee celebration in the auditorium of the Law School of Yale University and an institute of mental hygiene at which sessions were conducted for social workers, public health nurses and teachers. At the public meeting the speakers were, among others, Gov. Wilbur L. Cross, Charles-Edward A. Winslow, Dr. P.H., president of the society; Dr. Clarence M. Hincks, New York, general director, National Committee for Mental Hygiene in the United States and medical director of the Canadian Committee for Mental Hygiene, and Mr. Clifford W. Beers, founder of the mental hygiene movement.

Dr. Yandell Henderson Retires.—Yandell Henderson, Ph.D., who has been associated with Yale University since 1900, will retire as director of the laboratory of applied physiology, Yale University School of Medicine, New Haven, at the end of the academic year, according to *Science*. He will be succeeded by Dr. Howard W. Haggard, associate professor of applied physiology, who also becomes professor. Dr. Henderson was born in Louisville, Ky., April 23, 1873. He received his degree of doctor of philosophy at Yale in 1898 and at the universities of Marburg and Munich in 1899 and 1900 respec-

tively. He joined the staff at Yale in 1900 as instructor in physiology, becoming professor of applied physiology in 1921. An Associate Fellow of the American Medical Association, he served as secretary of its Section on Pathology and Physiology in 1909-1910 and as chairman in 1910-1911.

DISTRICT OF COLUMBIA

Dr. Parran Awarded Mendel Medal.—Dr. Thomas Parran, surgeon general, U. S. Public Health Service, has been awarded the Mendel Medal for 1938 by Villanova (Pa.) College in recognition of his scientific approach to the problems of public health. The medal was established by the college in 1929 as a mark of recognition for the work of the outstanding Catholic scientist of the year.

New Officers of District Society.—Dr. John H. Lyons, Washington, was named president-elect of the Medical Society of the District of Columbia at its annual session May 11, and Dr. William J. Mallory, Washington, was inducted into the presidency. Vice presidents are Drs. William T. Gill Jr. and David Davis. Dr. Coursen B. Conklin, Washington, was reelected secretary. The next annual session will be held in Washington May 3-4, 1939.

Hospital News.—The Medical Society of St. Elizabeth's Hospital, Washington, held its first annual dinner at the Kennedy-Warren Hotel, April 14. Dr. Winfred Overholser, recently appointed superintendent of the hospital, and Mrs. Overholser were guests of honor. Cloyd Heck Marvin, LL.D., president, George Washington University, was the speaker. It was announced that a portrait of the late Dr. William A. White, formerly superintendent of the hospital, would probably soon be presented to the hospital.

FLORIDA

Annual Short Course for Physicians.—The sixth annual graduate short course for physicians will be held at the Osceola Hotel, Daytona Beach, June 27-July 2, under the auspices of the Florida Medical Association and the state board of health. The instructors will be:

Dr. Maurice C. Pincoffs, professor of medicine, University of Maryland School of Medicine, Baltimore.

Dr. Wilbur Emory Burnett, associate professor of surgery, Temple University Medical School, Philadelphia.

Dr. Jesse O. Arnold, professor of obstetrics at Temple.

Dr. Alexander J. Schaffer, associate in pediatrics, Johns Hopkins University School of Medicine, Baltimore.

Dr. Robert J. Crossen, assistant professor of clinical obstetrics and gynecology, Washington University School of Medicine, St. Louis.

Dr. Beverley R. Tucker, professor of neuropsychiatry, Medical College of Virginia, Richmond.

Registration will begin promptly Monday morning June 27, although any one wishing to register in advance may do so through Dr. George C. Tillman, Gainesville. A registration fee of \$5 will be charged.

IDAHO

Society News.—At a meeting of the Pocatello Medical Society in Blackfoot, April 7, Dr. James O. Cromwell, medical superintendent of the state hospital at Blackfoot, discussed "Schizophrenia and Modern Treatment with Insulin Shock Therapy." V. R. Fisher, Ph.D., also on the staff of the hospital, spoke on negativism and suggestibility in schizophrenia.

Annual Registration Due July 1.—All practitioners of medicine and surgery holding licenses to practice in Idaho are required by law to register annually on July 1 with the department of law enforcement and at that time to pay a fee of \$2. If a licentiate has not paid the annual registration fee by October 1, his license can be canceled but will be restored within five years thereafter on payment of the delinquent fees and a \$10 penalty. If a license has been canceled for more than five years, it can be reinstated only on the payment of \$25 and on the licentiate's passing an examination, the nature of which shall be determined by the department of law enforcement.

ILLINOIS

Society News.—Dr. Morton Hamburger Jr., Chicago, discussed "Serum Therapy of Lobar Pneumonia" before the Kane County Medical Society April 13.—At a meeting of the Champaign County Medical Society in Urbana April 14 Dr. French K. Hansel, St. Louis, spoke on "Various Manifestations of Allergy."—Dr. James Paul Bennett, Chicago, addressed the Bureau County Medical Society April 12 in Princeton

on "X-Ray of the Chest and Mediastinum."—Dr. Paul H. Harmon, Chicago, discussed "Poliomyelitis: the Treatment of Acute Poliomyelitis" before the Morgan County Medical Society at Jacksonville April 14.—Dr. Leon Unger, Chicago, addressed the Winnebago County Medical Society at Rockford, April 12, on "Differential Diagnosis and Treatment of Asthmatic Conditions."

CHICAGO

Courses on Cancer.—James W. Cook, professor of chemistry, University of London, will present two courses on cancer at the University of Chicago this summer, June 15-July 21. One will be on "Cancer-Producing Chemical Agents and Their Biological Effects" and one on "Polycyclic Hydrocarbons and Their Relationship to Biological Problems." The latter course is concerned with the relationship of cancer to hormones.

Seek to Lower Maternal Mortality.—New regulations will be enforced in Chicago hospitals in an effort to reduce maternal deaths. In the future maternity divisions of hospitals are required to be separated from other services. There must be isolation quarters for infected mothers and a separate nursery for infectious infants. Delivery rooms must be separated from surgical and medical departments. Visitors in the maternity division must be limited to two a day in addition to the husband and must be excluded during nursing periods. Children may not be admitted. Contact with babies is prohibited and visitors must not be permitted to sit on the beds. Other provisions pertain to the personnel, sanitation and facilities used in the care of maternity patients.

INDIANA

District Meetings.—The Tenth District Medical Society was addressed in Michigan City April 8 by Drs. Percival Bailey, Chicago, on "Technic and Results of Operation for Brain Tumor"; Newell C. Gilbert, Chicago, "Cardiorenal Diseases," and Frederick H. Falls, Chicago, "Management of Eclampsia and Toxemia" and Reuben L. Kahn, Sc.D., Ann Arbor, Mich., "Interpretation of Some Paradoxical Reactions in Syphilis" and "Role of Skin Immunity and Allergy."—The Twelfth District Medical Society was addressed at the Potawatomi Inn, Pokagon, May 19, among others, by Dr. David Benjamin Martinez, Pittsburgh, on "Cesarean Section—Indications and Contraindications" and J. H. Muyskens, Ph.D., Institute of Human Adjustment, University of Michigan, on "The Emergent Process of Speech"; other speakers included some officers of the state medical association.—At a meeting of the Ninth District Medical Society in Noblesville May 17 the speakers included Dr. Norman R. Kretzschmar, Ann Arbor, on "Toxemias of Pregnancy"; in the evening, Jepson Cadou, Washington, D. C., and Indianapolis, addressed the banquet.

IOWA

State Medical Election.—Dr. Felix A. Hennessy, Calmar, was named president-elect of the Iowa State Medical Society at its annual meeting May 13 and Dr. Arthur W. Erskine, Cedar Rapids, was installed as president. Dr. Robert L. Parker, Des Moines, was reelected secretary. Des Moines was selected for the next annual meeting May 10-12, 1939.

Outbreak of Trichinosis.—Eight persons were reported ill with trichinosis in O'Brien County, according to the state medical journal. Four hogs had been butchered on a farm March 1. The woman developed diarrhea and abdominal discomfort March 7, after having eaten some of the raw pork. March 11 the mother, father and five children began eating smoked sausage; and they became ill, March 21. The symptoms were diarrhea, muscular pains, puffiness of the eyelids, swelling of the legs and body, urticarial lesions and itching. Some of the ground pork had been given to relatives in town; a girl became ill after eating uncooked meat but the mother and father, who ate only cooked meat, escaped infection. Examination of the sausage in the state hygienic laboratory showed it to be heavily infested with larvae of *Trichinella spiralis*. It was estimated that 27,000 larvae were present in five ounces of sausage, about 180 larvae per gram.

KANSAS

State Medical Election.—Dr. Clifford C. Nesselrode, Kansas City, was chosen president-elect of the Kansas Medical Society at its annual session May 12, and Dr. Noble E. Melencamp, Dodge City, was inducted into the presidency. Dr. Harry L. Chambers, Lawrence, is the secretary. The next annual meeting will be in Topeka May 1-4, 1939.

MAINE

State Medical Meeting.—The Maine Medical Association will hold its eighty-sixth annual meeting at Bar Harbor June 26-28 under the presidency of Dr. Ralph W. Wakefield, Bar Harbor. The program includes conferences on miscellaneous subjects and papers by the following, among others:

- Dr. Adam P. Leighton, Portland, The Low Transverse Cervical Cesarean Section.
- Dr. John R. Fraser, Montreal, Control and Management of Puerperal Infection.
- Dr. Fuller Albright, Boston, Endocrinology in Relation to Obstetrics and Gynecology.
- Dr. Frank H. Jackson, Houlton, Medical Publicity.

A symposium on acute respiratory infections will be presented by Drs. Frederick T. Hill, Waterville; Donald S. King, Boston; James L. Wilson, Detroit, and Edward D. Churchill, Boston. One on cancer will be conducted by Clarence C. Little, Sc.D., Bar Harbor, Maine; Miss Elizabeth Fekete, Bar Harbor; Arthur M. Cloudman, Ph.D., and John J. Bittner, Ph.D., all of the Roscoe B. Jackson Memorial Laboratory, Bar Harbor, Maine. Reunions of the alumni of Boston University, Johns Hopkins, Bowdoin, McGill and Harvard medical schools will be held and special luncheons for past presidents and county secretaries. The speakers at the annual banquet, at which "fifty year" medals will be presented, will include Gov. Lewis O. Barrows, Dr. Delmer Allan Craig, Bangor, on "The Doctor, Family Friend or Public Servant," and Dr. Frank H. Lahey, Boston, "The Medical and Surgical Management of Peptic Ulcer."

MARYLAND

New Officers of Medical Faculty.—Dr. Dean D. Lewis, Baltimore, was elected president of the Medical and Chirurgical Faculty of Maryland at its annual meeting April 27. Other officers include Drs. Victor F. Cullen, State Sanatorium; Frederic V. Beitler, Baltimore, and William D. Noble, Easton, vice presidents, and Dr. Walter D. Wise, Baltimore, who was reelected secretary. The next annual session will be held at Baltimore April 25-26.

Hospital News.—Construction will soon begin on additions at the Hospital for Women, Baltimore, to include a new four story wing, which will increase the capacity from ninety-five to 120 beds for adults; the improvements under consideration will cost about \$330,000. Work has begun on the new \$320,000 addition to the Negro branch of the Maryland Tuberculosis Sanatorium, Henryton; the unit is expected to be available for occupancy in November, with facilities for from 450 to 475 patients, an increase of 250 beds.

MICHIGAN

Appointments to Basic Science Board.—According to the state medical journal, the following have been appointed members of the recently created basic science board: Warren O. Nelson, Ph.D., Detroit; John P. Van Hartsma, Ph.D., Grand Rapids; Rev. Father George Shiple, Detroit, and Ralph C. Huston, Ph.D., Michigan State College, East Lansing. The appointees are all teachers who are not engaged in the actual practice of any of the healing arts. Another member will be selected from nominations among chiropractors, it was reported.

Graduate Course in Pediatrics.—The Michigan State Medical Society, the state department of health and the department of graduate medicine, University of Michigan, and the Michigan Chapter of the American Academy of Pediatrics sponsored a graduate course in pediatrics at Grayling, Traverse City, Petoskey and Alpena during May. Four lectures at weekly intervals made up the course and the instructors included:

- Dr. John L. Law, Ann Arbor, Management of Meningitis, Erysipelas, Scarlet Fever and Streptococcus Infections in General with Particular Reference to the Use and Abuse of Sulfanilamide.
- Dr. Wyman C. Cole, Detroit, Nontuberculous Infections in the Respiratory Tract as They Occur in Infancy and Childhood.
- Dr. James L. Wilson, Detroit, The Newborn Period: Asphyxia (role of analgesic in production of), Resuscitation, Hemorrhage, Atelectasis and Other Conditions of the Newborn.
- Dr. Joseph A. Johnston, Detroit, Nutritional Studies in Infant Feeding: Comparative Study of Various Types of Infant Feeding; Diet Requirement in the Older Child and the Adolescent; Relation Between Infection and Nutrition.

Society News.—Dr. Joseph Brennemann, Chicago, discussed "Bronchiectasis, Atelectasis, Emphysema and Allied Conditions in Children" before the Washtenaw County Medical Society in Ann Arbor April 12. The Oakland County Medical Society was addressed in Ann Arbor May 11; the speakers were, among others, Drs. Frederick A. Coller on "Surgical Aspects of Gastrointestinal Disease" and Raphael Isaacs, "Some Diagnostic Points in Diseases of the Lymph Nodes."

Carl E. Guthe, Ph.D., director of the museum of anthropology, University of Michigan, lectured in the evening.—The Bay County Medical Society and the Saginaw Valley Academy of Ophthalmology and Otolaryngology were addressed April 6 by Dr. William Mithoefer, Cincinnati, on "Nasal Sinus Problems of Interest to the General Practitioner."

MISSOURI

Endowment Fund for Medical Library.—The nucleus of an endowment fund for the library of the Jackson County Medical Society was derived from the proceeds of a tea May 6 given by the woman's auxiliary. The tea was designed as an antique exhibit and hobby show.

State Medical Election.—Dr. James R. McVay, Kansas City, was chosen president-elect of the Missouri State Medical Association at its annual meeting May 4, and Dr. Bernard W. Hays, Jackson, was inducted into the presidency. The next annual session will be held at Excelsior Springs.

District Meeting.—The Second Councilor District Medical Society was addressed in Hannibal April 7. The following, among others, spoke: Dr. Augustin P. Munsch, "Chronic Rheumatoid Arthritis"; Dr. Ralph A. Kinsella, "Streptococcus Infections and Sulfanilamide," and Dr. Cyrus E. Burford, "Urology in Children"; all are members of the staff of the St. Louis University School of Medicine, St. Louis.

Society News.—A symposium on undulant fever was presented before the St. Louis Medical Society April 6; the speakers were Drs. Omer E. Hagebusch, Harry G. Bristow, Roland S. Kieffer, Arthur H. Deppe, John Grey Jones and T. Wistar White. A symposium on office procedures in minor surgery was conducted before the society March 22; the speakers were Drs. Theodore H. Hanser on "Superficial Infections"; Edward L. Keyes, "Subcutaneous Tumors"; Robert W. Bartlett, "Ingrown Toenail"; Clinton W. Lane, "Warts, Moles and Keratoses," and Ralph M. S. Barrett, "Anesthesia in Office Practice."

NEW HAMPSHIRE

State Medical Election.—Dr. Clarence O. Coburn, Manchester, was elected president of the New Hampshire Medical Society at its recent annual session and Dr. James B. Woodman, Franklin, vice president. Dr. Carleton R. Metcalf, Concord, is the secretary.

NEW JERSEY

Dr. Stanley Awarded Rosenberger Medal.—Wendell Meredith Stanley, Ph.D., of the Rockefeller Institute, Princeton, will receive the Rosenberger Medal of the University of Chicago in recognition of his achievement in isolating crystalline forms of the filtrable viruses, it was announced May 25. The medal, founded by Mr. and Mrs. Jesse L. Rosenberger for distinguished achievement in the advancement of learning or for notably great service in the promotion of human welfare, has been awarded five times previously. Dr. Stanley received his degree of doctor of philosophy from the University of Illinois in 1929; he has been a member of the staff of the Rockefeller Institute since 1931.

Society News.—At a meeting of the Bergen County Medical Society in Bergen Pines May 10 Drs. Chevalier Jackson and Chevalier L. Jackson discussed bronchoscopy.—A symposium on comprehensive planning of medical care was presented before the Passaic County Medical Society in Paterson recently by Mr. Sherrard Ewing, executive director of the Paterson Community Chest and Social Planning Council; Emil Frankel, Ph.D., director, division of statistics and research, New Jersey Department of Institutions and Agencies, and Dr. Thomas K. Lewis, Camden, chairman, board of trustees and medical practice committee, state medical society.—Miss Margaret Ritchie, Newark City Hospital, Newark, was reelected president of the Association of Medical Record Librarians of New Jersey for her third successive term at its annual meeting May 4.—Dr. Ralph Colp, New York, discussed "Gallbladder Disease as a Surgical Problem" before the Academy of Medicine of Northern New Jersey May 26.

NEW YORK

Alumni Reunion.—The Association of the Alumni of Albany Medical College will hold its annual meeting and banquet at the Colonial Country Club, Albany-Schenectady Road, June 13.

State Medical Election.—Dr. Terry M. Townsend, New York, was chosen president-elect of the Medical Society of the State of New York at its annual meeting in New York City May 10. Dr. William A. Groat, Syracuse, was inducted

into the presidency. Dr. Walter W. Mott, White Plains, was elected a vice president and Dr. Peter Irving, New York, was reelected secretary.

New State Hospital Building Program.—About \$40,000,000 will be spent by the state in constructing public buildings, hospitals, schools and prisons through the use of funds authorized under the bond issue voted by the people at the last election, according to the *New York Times*. In the first year, beginning July 1, about \$26,000,000 will be spent. Most of this has been allotted to the department of mental hygiene. The plans include a state school for mental defectives with a capacity of 3,000 patients at a cost estimated at \$12,000,000. The site probably will be on Staten Island or elsewhere in the vicinity of New York City. The school is intended for male and female patients. An addition is now being erected to the building for infirm patients of the Brooklyn State Hospital which will increase the capacity for these patients by about 400 and will cost about \$437,000. Ten one story buildings for tuberculous patients will be added to the two existing buildings at the Central Islip State Hospital. This group of buildings will increase the patient capacity by about 1,000 and will house all the tuberculous patients for the hospitals under the department of mental hygiene in the metropolitan district. The cost of this project will be \$1,115,000. About 1,100 infirm patients at the Kings Park Hospital will be housed in a new building to be built at a cost of around \$1,940,000. At the Pilgrim State Hospital it is proposed to construct a group of interconnected buildings to care for about 1,500 patients, the cost to be about \$589,000. An addition is being constructed to the reception building at Creedmoor State Hospital which will increase its capacity by 100 patients and cost about \$1,940,000. Clinton prison at Dannemora is to have a new hospital for eighty-two general and 116 tuberculous inmates. It is intended to make this hospital the center for all tuberculous inmates in state prisons and the cost will be about \$630,000. A ward building is also to be erected at Dannemora State Hospital for Mental Cases with a capacity of 100 inmates, costing about \$122,000.

New York City

Plan for Free Maternity Care.—Every expectant mother in Brooklyn will receive full medical attention whether she can pay for it or not in accordance with a plan announced in the *New York Times* May 4. The plan is under the auspices of the Kings County Medical Society and provides that members of obstetric staffs in Brooklyn's forty-nine public and private hospitals will grant consultation when called on. Compensation will not be required except when the attending physician provides evidence that the patient can afford to pay for all or part of his services. Physicians attending maternity cases will be required to call consultants from the obstetric staffs in all instances in which complications develop, while interns will perform obstetric operations only if a member of the hospital staff is present. The new program was adopted following a survey by the committee on maternal welfare of the Kings County Medical Society.

Society News.—Dr. Kingsley Roberts addressed the Society of Medical Jurisprudence May 9 on "Relation of Voluntary Health Associations to a National Health Program."—Among others, Dr. William F. MacFee addressed the New York Surgical Society May 11, on "Malignant Tumors of the Salivary Glands."—The sixth clinical meeting of the Brooklyn Thoracic Society and the bureau of tuberculosis of the New York City Department of Health was addressed May 20 by Drs. Nagla M. Laf Loofy on "Case Finding Through Periodic Contact Examinations"; Mary R. Eleston, "Supervision of Primary Lesion in Children," and Herbert R. Edwards, "The Department of Health Program for the Control of Tuberculosis."—The section on laryngology, rhinology and otology of the Medical Society of the County of Kings gave a testimonial dinner to Dr. Wells P. Eagleton, Newark, N. J., May 11. Dr. Eagleton addressed the section meeting on "Toxic and Allergic Meningitis with an Overflow of Bacteria from the Ear, Nose and Throat."

New Cancer Hospital Nearly Finished.—The cornerstone of the new Memorial Hospital for the Treatment of Cancer and Allied Diseases was placed May 20. The speakers included Dr. James Ewing, director of the hospital, and the ceremonies were held on the anniversary of the laying of the cornerstone of the original Memorial Hospital fifty-four years ago. The structure when completed will cost about \$4,000,000, of which \$3,000,000 was originally granted by the General Education Board of the Rockefeller Foundation. The site,

opposite the Rockefeller Institute for Medical Research, the Cornell University Medical College and the New York Hospital, was given by John D. Rockefeller Jr. The twelve story penthouse building, which is nearly completed, will provide accommodations for 168 beds with provision for expansion. It will contain extensive facilities for diagnostic and treatment clinics, surgery, research laboratories and special provision for irradiation with x-rays and radium. According to the *New York Times*, the box placed in the cornerstone contained publications of the hospital; data on the present five year cure rates at the institution in the different types of cancer, external and internal; gold seeds filled with radon, and other radium applicators developed at the hospital; photographs of the nursing, laboratory, clinical, fellowship and resident staffs, and other articles and documents.

NORTH CAROLINA

Personal.—Dr. James Street Brewer, Roseboro, was appointed a member of the state board of medical examiners at its annual meeting in Pinehurst recently.—Dr. George Boyce Lynch, Brevard, has been appointed health officer of Transylvania County.

Society News.—The Buncombe County Medical Society was addressed in Asheville May 30 by Dr. Norris W. Vaux, Philadelphia, on "Breech Deliveries"; Dr. Walter R. Johnson addressed the society May 16 on "Value of the Galactose Tolerance Test in Differentiating Medical from Surgical Jaundice."—At a meeting of the Catawba Valley Medical Society in Morganton, May 10, the speakers were Drs. William L. Kirby, Winston-Salem, on "Newer Conceptions About Eczema" and John S. Gaul, Charlotte, "Fractures of the Extremities."—A symposium on pneumonia was presented at a meeting of the Iredell-Alexander County Medical Society, Statesville, March 8, by Drs. James P. Rousseau, Winston-Salem, Charles B. Herman, Charles L. Bittinger, Statesville, John Y. Templeton, Mooresville, and Joseph S. Holbrook.—Dr. Harry L. Johnson, Hickory, was elected president of the North Carolina Hospital Association at its annual meeting in Pinehurst April 13.—At a meeting of the Mecklenburg County Medical Society, Charlotte, April 5 the speakers were Drs. John Donnelly, Jasper S. Hunt and Andrew D. Taylor in a symposium on meningitis.

OHIO

Industrial Commission Names Silicosis Referees.—The Ohio State Industrial Commission has appointed three physicians as referees for claims to compensation for silicosis under the workmen's compensation law. Provision for the referees was made in a law recently enacted by the legislature adding silicosis to the list of compensable diseases. The appointees are Drs. Raymond C. McKay, assistant clinical professor of medicine, Western Reserve University School of Medicine, Cleveland; Joseph A. Muenzer, Toledo, formerly associated with the bureau of tuberculosis in the state department of health, and William M. Doughty, director of radiology at Christ Hospital and Children's Hospital, Cincinnati. All claims for disability or death due to silicosis will be referred to these physicians for examination and recommendation for all medical questions.

OREGON

Medical Coordinator Appointed.—Dr. Neil F. Black, Klamath Falls, health officer of Klamath County, has been appointed state medical relief coordinator. He will have charge of developing methods of handling medical aid to those receiving old age assistance, to the blind, and dependent children; he will also work with the profession and civil authorities in furnishing medical aid. Dr. Black graduated at the University of Oregon Medical School, Portland, in 1935.

PENNSYLVANIA

Society News.—Clinics were conducted at a meeting of the Cambria County Medical Society in Johnstown May 12 by Drs. Raymond W. McNealy and Chauncey C. Maher, both of Chicago; in the evening Dr. McNealy discussed "Some Phases of Gallbladder Surgery" and Dr. Maher, "The Problem of Hypertension."—Dr. Albert F. Doyle, Johnstown, addressed the Lebanon County Medical Society, Lebanon, April 12 on "Public Health Aspects of Syphilis." Dr. Hans May, Philadelphia, addressed a meeting of the society May 10 on plastic surgery.—The McKeesport Academy of Medicine was addressed May 23 by Dr. Frank A. Evans, Pittsburgh, on obesity.—Drs. Robert L. Gilman, Philadelphia, and William

W. Bolton, Upper Darby, discussed syphilis before a meeting of the Northampton County Medical Society, Bethlehem, May 20.—Dr. Carl E. Irvin, Harrisburg, addressed the Dauphin County Medical Society May 3 on "Diagnosis and Treatment of Undulant Fever."—Dr. George E. Bennett, Baltimore, addressed the Harrisburg Academy of Medicine recently on "Low Back Pain."—Dr. Wendell J. Stainsby, Danville, addressed the Shenandoah County Medical Society at its May meeting on chronic arthritis.

Philadelphia

Patterson Fellowship and Teaching Fund.—The Patterson Fellowship and Teaching Fund is to be established at Jefferson Medical College, in accordance with the will of the late dean of the college, Dr. Ross V. Patterson. Two trust funds for \$60,000 each and one for \$30,000 were set up in the will but on the deaths of the beneficiaries the money will be used for the fellowship and teaching fund. It will go to graduates "whose records indicate ability beyond the average, to make possible to them further medical study, investigation and training, the better to fit them for careers in the practice of medicine, in medical teaching, in public health service, or in research." During such training the recipients are to be known as "Patterson Fellows." The will also stipulates that the fund be used to pay salaries of full time teachers in the Training School for Nurses of the Jefferson Hospital. Newspapers report that, if for any reason the college cannot accept the benefaction, it is offered in the order named to the University of Pennsylvania, Temple University and University of Pittsburgh.

TENNESSEE

Dr. Mallowney Retires as President of Meharry.—Dr. John J. Mallowney, since 1921 professor of public health and president of Meharry Medical College, Nashville, has announced his retirement, effective July 1. He will be succeeded by Dr. Edward L. Turner, professor of medicine. Dr. Mallowney was born in Seacombe, England, July 20, 1878, coming to the United States in 1887. He received his degree in medicine at the University of Pennsylvania School of Medicine, Philadelphia, in 1908. He served as professor of nervous and mental diseases, North China Union Medical College, Peking, 1908-1911; inspector of tenement and lodging houses, Philadelphia, 1912-1913; assistant chief of the Pennsylvania State Department of Health, 1913-1917, and head of the department of science and professor of chemistry and hygiene, Girard College, Philadelphia, 1917 to 1921 when he went to Meharry. Dr. Turner graduated at the University of Pennsylvania School of Medicine in 1928.

TEXAS

Surgical Meeting.—The Texas Surgical Society met in Houston April 4. Dr. Elbert Dunlap, Dallas, gave the president's address on "Surgical Diagnosis." The other speakers were:

- Dr. Nathan A. Womack, St. Louis, The Diagnosis of Cancer of the Bronchus.
- Dr. Edward White, Dallas, Perinephric Abscess.
- Dr. Eutus P. Bunkley, Stamford, The Perforated Peptic Ulcer.
- Dr. Charles C. Cade, San Antonio, The Conservative Treatment of Carcinomas.
- Dr. Walter G. Stuck, San Antonio, Peripheral Nerve Injuries Complicating Fractures.
- Dr. Gomer F. Goff, Dallas, Sulfanilamide in Pelvic Infections.
- Dr. George W. N. Eggers, Galveston, Elbow Fractures.
- Dr. George R. Enloe, Fort Worth, Obstructive Lesions of the Colon.
- Dr. Herbert T. Hayes, Houston, Electrocoagulation of Tumors of the Rectum.
- Dr. Albert O. Singleton, Galveston, The Anatomy of the Sympathetic Nervous System.
- Dr. John T. Moore, Houston, The Physiology of the Sympathetic Nervous System.

The next meeting will be held in Galveston in October.

WISCONSIN

Personal.—Harry Steenbock, Ph.D., professor of agricultural chemistry, University of Wisconsin, known for his work on vitamins, will receive an honorary degree at the university commencement June 20.—Dr. William D. Stovall, professor of hygiene, University of Wisconsin Medical School, Madison, has been appointed acting superintendent of the State of Wisconsin General Hospital, Madison, during the leave of absence of Dr. Robin C. Buerki to become director of study of the commission on graduate medical education.—The Medical Society of Milwaukee County gave a dinner in honor of Mr. Theodore Wiprud recently, following his resignation as executive secretary to accept a similar position with the Medical Society of the District of Columbia. Dr. Eben J. Carey, dean and professor of anatomy, Marquette University School of Medi-

cine, was toastmaster and the speakers included Drs. Raymond G. Arveson, Frederic; Stanley J. Seeger, Milwaukee; Rock Sleyster, Wauwatosa; Ralph P. Sproule, Edward L. Tharinger and John S. Gordan, Milwaukee. Mr. Wiprud was presented with a set of golf clubs by the society.

GENERAL

Alumni Smoker.—Alumni of Jefferson Medical College, Philadelphia, will hold a smoker at the Union League Club, 555 Post Street, San Francisco, June 15.

Medical Women's Association.—The twenty-third annual convention of the American Medical Women's Association will be held in San Francisco June 12-14, with headquarters at the Fairmont Hotel. The program includes the following speakers:

- Dr. Anita M. Muhl, San Diego, The Doctor's Mental Attitude.
- Dr. Ann P. Purdy, San Francisco, Nutrition.
- Dr. Kathleen M. Murphy, San Francisco, Relationship of the Estrogenic and Gonadotropic Hormones to Climacteric Symptoms.
- Dr. Olga L. Bridgman, San Francisco, The Psychiatric Aspect of the Juvenile Court.
- Dr. Evelyn M. Anderson, San Francisco, Clinical Conditions Related to the Adrenal Cortex.
- Dr. Amy N. Stannard, Berkeley, Calif., Family Relationship Affecting Delinquency.

Meeting of Medical Librarians.—The fortieth annual meeting of the Medical Library Association will be held at Boston June 28-30 at the Hotel Somerset. Sessions will be held at the Boston Medical Library and Harvard Medical School with open house in the libraries of the city. The speakers will include Drs. Henry R. Viets, Boston, Sanford V. Larkey, Baltimore, John F. Fulton, New Haven, Conn., and Mrs. Eileen R. Cunningham, Miss Isabelle T. Anderson, Mr. James F. Ballard and Mr. Herman H. Henkle, director, school of Library Science, Simmons College, who will conduct an institute for medical librarians. Other features will include symposiums on a "Guide to Medical Literature" and "Medical Literature of the Past."

Meeting of Urologists.—The American Urological Association will hold its annual meeting in Quebec June 27-30 under the presidency of Dr. David W. MacKenzie, Montreal. The program includes a symposium on sulfanilamide with the following speakers: Drs. Eli K. Marshall Jr., Baltimore; Edwin P. Alyea, Durham, N. C.; John A. C. Colston, Baltimore; James I. Farrell, Evanston, Ill.; Clarence R. O'Crowley, William L. James and Harold Lawrence Sutton, Newark, N. J.; Pearl F. Summerfeldt and David R. Mitchell, Toronto, and John L. Crenshaw and Edward N. Cook, Rochester. The following, among others, will speak:

- Drs. Charles J. E. Kickham and Norman H. Bruce, Boston, Urologic Complications in Malignant Disease of the Rectum.
- Drs. Dorrin F. Rudnick and Edward L. Cornell, Chicago, Strictures of the Ureter in the Female.
- Dr. Arthur Elmer. Belz, Los Angeles, A New Anatomic Approach to the Prostatic Capsule in Perineal Prostatectomy.
- Drs. Ernest Rupel and Richard C. Travis, Indianapolis, Mandelic Acid Therapy: Action of Enteric Coated Tablets of Mandelic Acid (as Monoethanolamine Mandelate) and Ammonium Chloride.

David L. Thomson, Ph.D., Montreal, will deliver the Ramon Guiteras Lecture on "Endocrinology in Its Relations to Urology."

Special Society Elections.—Dr. Walter R. Steiner, Hartford, Conn., was elected president of the American Association of the History of Medicine at its annual meeting May 2 and Dr. Henry E. Sigerist, Baltimore, was elected secretary. The next annual meeting will be in Atlantic City in May.—At the annual meeting of the American Association of Pathologists and Bacteriologists May 4 the following officers were elected: Drs. Earl B. McKinley, Washington, D. C., president; Carl V. Weller, Ann Arbor, vice president, and Howard T. Karsner, Cleveland, secretary. The next annual session will be held at Richmond, Va., April 6-7.—Dr. Oscar B. Hunter, Washington, D. C., was elected president of the American Therapeutic Society at its annual meeting April 2, and Dr. Joseph F. Elward, Washington, D. C., secretary.—Dr. Stephen W. Ranson, Chicago, was chosen president of the American Association of Anatomists at its meeting April 14 and Dr. Eliot R. Clark, Philadelphia, was named secretary. The next annual session will be held at Boston April 6-8.—Dr. Frank D. Dickson, Kansas City, Mo., was chosen president-elect of the American Orthopedic Association at its annual meeting May 5; Dr. William W. Plummer, Buffalo, N. Y., is president, Dr. Ralph K. Ghormley, Rochester, Minn., was reelected secretary. The next annual session will be held at Buffalo.—Dr. Tinsley R. Harrison, Nashville, Tenn., was elected president of the American Society for Clinical Investigation at its annual meeting May 2 and Dr. Isaac Starr Jr., Philadelphia, was chosen secretary.

CANADA

Balfour Lecture.—Dr. Gordon Gordon-Taylor of the staff of Middlesex Hospital, London, England, delivered the Donald C. Balfour Lecture in Surgery at the University of Toronto April 5. His subject was "Gastric Hemorrhage."

Society News.—Dr. Henricus J. Stander, New York, addressed the Academy of Medicine of Toronto, March 1, on "Cardiac Disease in Pregnancy."—Dr. Lyon H. Appleby, Vancouver, delivered the Osler Lecture of the Vancouver Medical Association March 1; his subject was "Quo Vadis, Medicina?"

Anniversary of Medical Library.—The *Bulletin* of the Academy of Medicine of Toronto dedicated its April issue in honor of the fiftieth anniversary of the Ontario Medical Library Association. The first annual meeting of the association, formed by the Toronto Medical Society, the Ontario Medical Association and the College of Physicians and Surgeons of Ontario, was held July 13, 1888. At the annual meeting of 1889 it was reported that the association had ninety-one members, 1,300 bound and 250 unbound volumes in the library and fifty-nine journals on file. In 1907, when the academy of medicine was organized with the library as its nucleus, it had 4,602 volumes and now has 27,065. The first book presented to the library was a copy of Oliver Wendell Holmes's "Medical Essays" with an inscription by the author. The special issue of the bulletin describing the collections in the library, especially mentions the influence of Sir William Osler, who throughout his life made many gifts to the library. One of the prized possessions is a collection of medical portraits made by Sir William and presented by his brother, Sir Edmund Osler, in 1909. A recent addition is a collection of about 200 volumes on pathology assembled by the late Prof. Oskar Klotz.

Government Services

Dr. Treadway Placed in Charge of Narcotic Farm

Dr. Walter L. Treadway, assistant surgeon general, U. S. Public Health Service, Washington, D. C., has been appointed medical officer in charge of the federal narcotic farm at Lexington, Ky., succeeding Dr. Lawrence Kolb, who is transferred to Washington to become assistant surgeon general. Dr. Treadway was assistant physician of the Jacksonville (Ill.) State Hospital from 1908 to 1912. He was commissioned as assistant surgeon general in the public health service in 1913 and was made chief of the division of mental hygiene of the service in 1930. Dr. Kolb has been medical director of the narcotic farm, the first of its kind, since its opening in 1935. He graduated at the University of Maryland School of Medicine in 1908.

Warning on Filled Milk Act

The Food and Drug Administration of the U. S. Department of Agriculture warns that it will institute legal action against all interstate shipments of any product falling within the statutory definition of filled milk. The warning follows the recent decision of the U. S. Supreme Court in the case of *United States v. Carolene Products Company*, which upheld the Federal Filled Milk Act of 1923 as constitutional. By its terms the act prohibits the interstate distribution of any combination of milk, cream or skimmed milk with any fat or oil other than the milk fat so as to resemble or imitate milk or skimmed milk in any form. The legislation was enacted after a congressional hearing. Congress determined and declared "That filled milk, as herein defined, is an adulterated article of food injurious to public health and its sale constitutes a fraud upon the public." The indictment in the *Carolene* case alleged the unlawful interstate shipment of "Milknut" and "Carolene" manufactured by Carolene Products Company of Litchfield, Ill. Analyses by the Food and Drug Administration showed the products to be composed essentially of evaporated skim milk and coconut oil in semblance of evaporated whole milk. After prosecution was started, the manufacturer filed a demurrer to the indictment on the ground that the act was unconstitutional. The demurrer was sustained by the federal court for the Southern District of Illinois. The United States appealed to the supreme court of the United States, which upheld the filled milk act as constitutional, according to a release from the U. S. Department of Agriculture.

LONDON

(From Our Regular Correspondent)

May 14, 1938.

Advance in the Treatment of Cancer

At the annual meeting of the Royal Cancer Hospital, Mr. Cecil Rowntree, senior surgeon, said that the hospital was now supplied with the latest and most efficient apparatus that it was possible to wish for and that they had consolidated the somewhat tentative conclusions toward which they had gradually been feeling their way. "We have now learnt," he continued, "the best ways of dealing with the widely different types of malignant disease. We now know which are the types of cancer best treated by purely surgical operation. We know that in other forms, such as cancer of the tongue, mouth and throat, we can confidently expect such results from radium bomb treatment as have never been equaled or even approached by any other form of therapy and with the Schaoul type of x-ray machine we are constantly and consistently curing such diseases as cancer of the lip and face and cancer of the skin with such certainty, simplicity and safety as has never been experienced before. In fact, give us a case of cancer in any of these situations in a reasonably early stage, and we will now guarantee its complete and speedy disappearance."

Rapid Decline of London's Child Population

The London County Council has just published a new edition of the Statistical Abstract for London, which shows a rapid fall of the child population. In 1937 only 417,028 children were attending public elementary schools, as compared with 560,527 ten years previously. Thus the child population declined by more than a fourth in this short period, and if this rate of decline should continue for fifty years the total at the end of that period would become less than a fourth of the present number. This decline of child population shows what is not generally understood—why a fall in our general population is inevitable under the present birth rate although our population still shows an annual increase. The reason is that children are not being produced in sufficient number to replace their predecessors, while the level of population is being maintained by the number of adults and their greater longevity. But this effect can be only temporary, as the level of population must ultimately depend on the number of children born and reared. Indeed, the fall of the general population is not far off. It is calculated that in 1940 or thereabouts our population will reach its maximum and then begin to decline, at first slowly and later more rapidly.

Vulvovaginitis in Children

The London County Council has now the largest hospital system in the world, containing 36,000 beds in which all kinds of specialization are carried out. It has had a wide opportunity for observing vulvovaginitis in children and has for more than two years maintained a careful watch for this disease among the many thousands of children under its care. It has just published a report in which medical superintendents of its hospitals, gynecologists, pediatricians and pathologists have cooperated. In the period mentioned, 627 cases of vulvovaginitis were discovered in the council's general and special hospitals, residential schools and homes and nurseries for infants, of which only thirty-two were found to be gonococcal, and in the great majority of the latter were nonsexual in origin.

GNONOCOCCIC VULVOVAGINITIS

Infection is usually accidental, the result of contamination of the vulva with infected fomites, such as towels, sponges, bed linen or lavatory seats. The manner in which material for bacteriologic diagnosis is collected is of great importance. Swabs

should be taken only by a clinician expert at the task. A probe mounted with absorbent cotton must be passed well into the vagina and withdrawn with some discharge on it. In the treatment no packing of the vagina should be carried out and only nonirritating lotions should be used, such as 0.5 per cent strong protein silver. Estrogen in daily doses of from 3,000 to 6,000 units by mouth has proved useful. Sulfanilamide has given encouraging results, but it is too soon to assess its value. The vulva should be swabbed with a lotion and dusted with a drying powder as often as is necessary to keep it free from pus and as dry as possible. There is a tendency to relapse. Criteria of cure are negative tests (films, cultures and gonococcus complement fixation) for a minimum of four months.

NONGONOCOCCIC VULVOVAGINITIS

Nongonococcal vulvovaginitis is not uncommon between the ages of 2 and 7 years. It may be due to acute specific infections (chickenpox, measles and scarlet fever), acute throat infections or foreign bodies. Differentiation between the various types can be made only by bacteriologic tests, though clinical signs are highly suggestive. Thus, in diphtheroid infections, redness of the vulva with scanty discharge is present. Foreign bodies produce a blood-stained offensive discharge; staphylococci, a thick creamy discharge; streptococci, a thinner colorless discharge; *Bacillus coli*, an offensive discharge with characteristic odor. The treatment calls for considerable judgment. Many cases are mild and require little except baths and local cleanliness. Severe cases should be treated on the same lines as gonococcal cases. The great majority of cases clear up in two or three weeks.

ADMINISTRATIVE ASPECTS

Administrative aspects are of great importance, as an organization undertaking the care of children, sick or healthy, has two obligations: (1) to protect noninfected children from infection; (2) to detect, isolate and treat any case. In the council's schools and receiving homes the children's underclothing and bed linen are watched for evidence of discharge. For obvious reasons the examination of any little girl is not a light matter but must be undertaken if necessary. If there is definite evidence of vulvovaginitis, she must be transferred to a hospital. It is the practice of the council to concentrate at a special hospital all cases in which a report is made of the presence of "organisms morphologically resembling the gonococcus."

PARIS

(From Our Regular Correspondent)

May 14, 1938.

Decline in Birth Rate Alarms France

The drop in birth rate as compared to the increase in the number of deaths is causing much anxiety here. The present and future defense of the country calls for a birth rate which is at least equal to that of Germany and Italy. In these two countries there has been a constantly increasing excess of births over deaths during the past five years. A committee was appointed several months ago by the Académie de médecine of Paris to study methods of checking the drop in birth rate. At the April 26 meeting Professor Lereboullet submitted the report of the committee. The chief causes of the decline in the birth rate were found to be contraceptive methods and the widespread use of abortifacients or induced abortion. There were only 630,000 births in 1937 as compared to a little over a million in 1876. From 1935 to 1937 inclusive there were 57,117 more deaths than births in France, as compared to an excess of 950,000 births over deaths in Germany and of 775,000 in Italy during 1936 and 1937. The committee believed that the causes of the denatality in France were chiefly moral and economic. The following were the recommendations of the committee:

1. That the gravity of the denatality question be made known to the public by every possible method.

2. That an appeal be made to the moral and spiritual forces of the country to encourage the raising of large families, by granting large subsidies which increase proportionately to the number of children.

3. That the danger of induced abortions be impressed on the women of the country and that the laws already in existence which entail imprisonment and heavy fines for abortionists be rigorously applied.

Polycystic Disease of the Pancreas

Only ten reported cases of polycystic disease of the pancreas could be found by Loeper, Lemaire and Lesobre, who have published a personal observation in the May 7 issue of *Progrès médical*. Polycystic disease of the pancreas, although related to unilocular or multilocular cyst formation, so far as its pathogenesis is concerned, differs from these more common conditions in its gross and microscopic appearance as well as in its clinical manifestations. Polycystic disease of the pancreas is characterized by the formation of multiple minute cysts similar to those found at times in the parotid, breast, liver, kidney and ovary. The patient in question was a woman aged 77 who was admitted to the service of Professor Loeper Sept. 13, 1937, complaining of a severe diarrhea of a month's duration. Examination revealed an intense icterus, the urine containing both bile salts and pigments and stools, which although clay colored often showed the presence of blood. The clinical picture was that of an obstructive jaundice. The lower margin of a firm liver was felt three fingerbreadths below the costal arch, and the distended gallbladder could be plainly outlined on palpation. There was a marked loss of weight and a severe pruritus. The patient died five weeks after admission. At the necropsy a greatly enlarged liver and distended gallbladder and common duct were first noted. The head of the pancreas was hard and, on section, the pancreas presented innumerable cysts varying in size from that of a lentil to that of a pea. On microscopic study these cysts were seen, for the most part, to be empty, a few showing several layers of cylindric epithelium. But little pancreatic tissue was to be found anywhere, but there was a hyperplasia of the few persisting islands of Langerhans. The latter finding could explain the absence of a glycosuria which had been noted clinically. Sections of the liver, on microscopic examination, showed all the typical changes of an obstructive jaundice.

Of ten reported cases, in three the polycystic disease of the pancreas had not given rise to symptoms and was found at necropsy; in two cases there was an accompanying severe diabetes, one of the patients dying in coma; two showed clinical evidences of obstructive jaundice, one with glycosuria; only one presented symptoms of indigestion and the tenth patient had a progressive cachexia with anemia and steatorrhea.

It is impossible at present to explain the origin of this polycystic condition of the pancreas, except on a congenital basis.

Program of 1938 French Pediatric Congress

The tenth annual meeting of the French Pediatric Congress will take place October 6-8. The meeting place is the medical amphitheater of the Paris Children's Hospital. The following will form the subjects of special reports and general discussion:

1. Severe anemias in infancy, by Dr. Louise Weill of Lyons.
2. Toxi-infections in infancy, by Dr. R. A. Marquiez and Miss Ladet.

3. Megalocolon and dolichocolon, by Drs. Rohmer and Boppe.
American pediatricians who wish to take part in the discussions are asked to write to Dr. Maurice Lamy, 94 rue de Varenne, Paris (7).

Program of Seventeenth Annual Neurologic Reunion

This year's neurologic reunion will be held May 31 and June 1 at the Hôpital Salpêtrière, where the late Professor Charcot held his clinics. The chief subject for discussion will

be the role of the pupil in neurology. Papers will be read by Drs. Bollock, Edouard Hartmann, Monbrun, Velter and Tournay. Particular attention will be paid first to objective study (pupillometry) of the pupil while at rest and the pupillary reactions; second, to changes in the pupils in disease and, third, to search for physiopathologic explanations of the preceding. Other papers include as subjects cerebral blood supply, experimental polyneuritis, toxic epilepsy, nervous complications of leukemia and diagnosis and indications for operative intervention in craniocerebral injuries.

Program of 1938 Meeting of French Medical Congress

The twenty-fifth annual French Medical Congress will be held September 26-28 inclusive at Marseilles under the presidency of Professor Olmer. The subject chosen for reports and discussion are (1) spirochetosis of infectious jaundice, (2) hypochloremia and (3) present day treatment of avitaminoses in adults. American physicians who wish to attend the congress can receive information by writing to Prof. Henri Roger, 66 Boulevard Notre-Dame, Marseilles.

Proposed Statue to Honor the Memory of Laënnec

At a meeting of the Assemblée française de médecine held in May 1936 at the birthplace of the internationally known clinician Laënnec it was decided to ask for subscriptions to erect a monument near the site of the former Charity Hospital in Paris, where Laënnec taught for many years.

April 19, 1938.

News of the Universities

One of the important functions of a university is to maintain an adequate supply of prospective professors. Many qualified young scholars, however, find it impossible to remain at the universities as docents without financial assistance, and this economic consideration threatens a real shortage of younger teachers. Regulations relative to the compensation of docents have recently been planned to provide an official subsidy for every graduate who receives a teaching certificate. The young scholar would thus be guaranteed a steady means of livelihood. It seems that a critical situation has been developing in which promising young docents were forced to quit the universities for economic reasons and to seek a livelihood in other fields. The new plan was scheduled to go into effect April 1 but its inauguration has as yet not been possible. Temporary reforms to aid needy docents have, however, been introduced. Special subsidies are available to a docent who has a scholastic record and a personality which augur well for a successful academic career, good moral character, a disposition to act at all times "unreservedly in harmony with the national socialist state and to be an active exponent of the national socialist weltanschauung," and, further, eligibility under the German statute governing the racial extraction of public employees, an earnest desire to be of service to the university, and, finally, economic circumstances that justify the granting of a subsidy. A whole series of further conditions, based on the merits of the individual case, is imposed at the time the assistance is granted. A subsidy is extended for a period of two years but may be stopped sooner if reasonable grounds for dissatisfaction with the docent's academic activities develop or in the event of other disqualifying circumstances. Rectors of the universities and deans of the faculties are required to report any circumstance that might be a basis for disqualification. Other officials, the local *fuehrers* of docents, for example, may of their own initiative propose the revocation of a grant.

The statute to regulate dueling among students has lately undergone revision. There is a tendency to enlarge the jurisdiction of the student courts of honor. This trend has a justi-

fiable basis in the formerly too great powers of the courts of honor; these tribunals often undertook to decide cases that related to "honor" in only the most superficial sense and which really had to do with gross breaches of discipline. Under the last named classification fall all instances of public insults, malicious slander and unprovoked jostling which are perpetrated by a student while in an intoxicated or semi-intoxicated state. The new law places a more limited construction on the term "case of honor"; a valid case must now be based only on genuine, serious, deliberate affronts to a student's honor. Weapons must no longer be taken up for every trifling provocation.

The rules of the duel have been altered. Pistol duels among students are prohibited. In place of the stationary fencing bout, the "starke mensur" fought with heavy sabers, the law prescribes the mobile mensur with the light Hungarian saber. Moreover, the national *fuehrer* of students has until further notice reserved to himself the right of passing on the legality of all saber duels approved by the courts of honor. (The foregoing regulations do not apply to the military duel; the army has a code of its own which is much more stern than that of the students. It sanctions, for example, a pistol duel that must be carried on until one party is *hors de combat*.)

Officialdom has recently become particularly interested in improved dental services for students. Special dental services are to be made available to all university students. The fees asked for filling teeth will be fixed by law. Students unable to pay for such service will be treated free of charge; 220,000 marks has been allocated for this purpose by the government.

Finally, the *anschluss* with Austria has made necessary a vast number of changes within the universities of the annexed territory. The data available with regard to these changes are herewith summarized: The Austrian minister of education, Dr. Menghin, has issued decrees designed to place the universities in line with the new régime. Orders have been given for the dismissal of certain faculty members and the installation of new academic functionaries. Regulations governing examinations which derived from the political complexion of the late Austrian republic were immediately set aside when the nazis came to power. To keep the Austro-German universities from becoming overalienized by Jewish matriculants, the minister has imposed restrictions on the enrolment of Jewish students. No further registrations of Austro-German Jews will be accepted for the summer semester of 1938; already accepted registrations of Jews will be allowed to stand for the time being subject to cancellation. In future a numerus clausus of Jewish students will be established. Special rules apply to the matriculation of foreign Jews.

It has been decreed that all members of academic faculties who on racial or political grounds were unable to take the oath of allegiance to Adolf Hitler, and all those who were arrested or dismissed from their posts at the time the nazis took over, are until further notice ineligible for academic service. The former statute of higher education has been nullified. The government expects that former students who were expelled from the universities under the last mentioned law as adherents of the nazi movement will now resume their interrupted studies.

Vienna University has already lost a number of professors through dismissal. Professor Arzt, ordinarius in dermatology there, appears to be among those removed. Arzt is not a Jew. For many years he has been editor-in-chief of the *Wiener klinische Wochenschrift* but on the cover of the April 1 issue (No. 13) his name is absent from the accustomed place and in its stead appear the words "acting editorial staff." Whether this means that Arzt's connection with the journal is definitely severed cannot be stated at the present writing.

Dr. Kronfeld has for several decades edited the *Wiener medizinische Wochenschrift* and has also been especially active in the organization of international graduate study at Vienna. The April 2 (No. 14) issue of this journal carried the name

a new editor. Moreover, page 1 of this issue was given over to an appeal for support of the new régime and an announcement that the publication had been transferred to "Aryan ownership, Aryan management and Aryan editorship."

The Acceleration of Development in Childhood

It is common knowledge that an acceleration in the rate of growth among children has been reported from various countries. Dr. Bennholdt-Thomsen, senior physician at the children's hospital of the university of Frankfurt on the Main, has recently attempted to establish the scientific basis of this remarkable change by means of a questionnaire survey of girls in Hesse-Nassau province. On the basis of this study he formulates the following conclusions: (1) The growth of the present generation of children is more rapid as against that of earlier generations, (2) city children are taller than country children, (3) within the cities children whose parents are in good economic circumstances are taller than children of the poorer classes, (4) more premature appearance of the centers of ossification (evaluated as another sign of development) also takes place earlier among the city children with good economic backgrounds than among the poorer children, (5) menstruation unquestionably begins earlier among the present generation as against earlier generations, (6) city girls begin to menstruate at an earlier age than country girls, (7) among the urban population, daughters of well-to-do parents located in the largest cities menstruate earlier, whereas girls of the slum areas menstruate latest, (8) in a majority of families the daughters menstruate at an earlier age than did their mothers, (9) both primary and secondary dentitions, the former in particular, occur earlier among the daughters as contrasted with the mothers and (10) even with respect to the earlier eruption of primary dentition the geographic sequence remains: city, small town, country; this phenomenon too is manifested earlier among city children.

The author advances the following explanation of this earlier development: Emigration of the restless, more lively elements from the rural community has led to a great accumulation of nervous, sensitive, impressionable types of people in the urban areas. These elements have further multiplied within the city. Meanwhile the many sided phases of urban life have come to exert a cumulative effect on this more intelligent group of the population. The result has been an earlier beginning of growth and an accelerated rate of development among the youth of today. As a possible means of combating this phenomenon the author suggests planned decentralization to curb the further growth of the mammoth metropolis of today and an attempt to induce the struggling urban masses to return to the land.

Eightieth Birthday of Professor Pfeiffer

Prof. Richard Pfeiffer of Breslau, bacteriologist, celebrated his eightieth birthday March 27. Pfeiffer began his professional career as a military surgeon. From 1887 to 1891 he served as assistant to Robert Koch and in the latter year was appointed director of the Scientific Section of the Prussian Institute of Infectious Diseases, Berlin. In 1897 he served on the German Commission for Investigation of Plague in India and in the following year, with Robert Koch, he studied malaria in Italy. Pfeiffer became *ordinarius* in hygiene at Königsberg in 1899 and assumed in 1909 a similar post at Breslau, where he served until his retirement in 1925. He was the first to describe the development of the Coccidia. Best known and most associated with his name was the discovery and isolation of the influenza bacillus in 1892. Pfeiffer's phenomenon is of great value in the diagnosis of cholera. With Wilhelm Kolle he developed methods of immunization against typhoid, cholera and plague. His studies of the delimitation of resistance by genuine active immunity have become fundamental principles of immunology. His textbook of microbiology is perhaps the best known of his publications.

The Antianaphylactic Action of Vitamin C

Dr. Nitulescu made experiments by regularly giving from 100 to 200 mg. of vitamin C daily to children who were inoculated with antidiphtheritic serum, with a view of preventing anaphylaxis. His experience in these experiments was that vitamin C is actually capable of preventing anaphylaxis, though not in every case. Among forty-one children who received vitamin C, only six had anaphylactic symptoms, while among forty-five children not receiving vitamin C twenty-one had serum disease. Nitulescu states that continental experimenters are administering vitamin C also to overcome intolerance to arsphenamine. They state that by adding from 0.05 to 0.1 Gm. of ascorbic acid to the arsphenamine solution one can administer it to persons who otherwise could not bear it at all. They applied vitamin C orally too but the result was not satisfactory.

Hastening Healing After Operations

Dr. Campeanu, lecturer at the University of Bucharest, who is well known beyond the boundaries of Rumania, has methodically diminished the time spent in bed by surgical patients and at present he puts his patients on their feet directly from the operating table. During the period 1934-1938 3,150 laparotomized patients left their beds on the day following the operation. They did not experience any disadvantage that might have been caused by the early rising. Occasionally a patient observed some vertigo, but this may be observed also in patients kept in bed for the usual longer period. Encouraged by the experiences gained with the 3,150 patients, Campeanu went further and since Jan. 11, 1937, patients operated on under local anesthesia have been put on their feet directly from the operating table, whatever the operation may have been. Every patient was instructed to behave just like any other convalescent patient. They dressed themselves or with the help of a nurse. They went alone to the ward or to the hospital grounds and walked up or downstairs. Some of them walk in the park after the operation; others read books or listen to the radio. There are patients who take gymnastics, but there are also some who on reaching the ward take a rest in bed.

On the second day after operation patients who have been operated on under general or spinal anesthesia are similarly dealt with. Patients operated on for appendicitis or hernia, if living in Brasov, where Dr. Campeanu operates, are dismissed from the hospital on the third or fourth day, those from the country on the fourth or fifth day. They return on the seventh or eighth day for the removal of the sutures. In none of the 1,300 patients were there any complications which could have been the result of early rising. On the contrary, the patients remained free from such complications as pulmonary congestion or thrombophlebitis. All authors who have experimented with getting their patients out of bed early have found that motion is the means which prevents stasis. Campeanu says that motion promotes leukocytosis and that getting up immediately is a psychic as well as a physical stimulant, which curtails the duration of the disability. An assistant of Campeanu whose appendix had been removed, after having stepped down from the operating table, forthwith acted as assistant at the next operation and afterward walked about. His recovery was prompt. By shortening the stay of patients in the hospital, the surgical section of Campeanu's clinic in Brasov were able with the same number of beds to accommodate 500 more patients than in the previous year. This new method is of inestimable advantage in time of war. The evacuation of war

hospitals thus becomes simplified. Contraindications for such early rising are general debility of a major degree, high fever, serious complications on the part of other organs, and abdominal drainage. Of the 1,300 patients, three died: one of a perforated duodenal ulcer on the thirty-fifth day after operation caused by general peritonitis; one of pulmonary cancer well after the operation, as a result of hemoptysis from a mediastinal blood vessel; the third on the fourth day after unsuccessful decapsulation of the kidney from anuria due to mercury poisoning.

In Memory of the Late Professor Babes

On May 6, 1888, in Rumania the first antirabic injection was given to a patient bitten by a dog suspected of being infected with rabies. The physicians of the country celebrated, amid great solemnities, the memory of the founder of the Bucharest antirabic institute, Dr. Victor Babes, whose name is internationally known. The arranging committee gave a scientific character to the festivities by having lectures relating to the present status of the problem of rabies. The festivities were held in the Bucharest Babes institute. The committee on arrangements was headed by Professors Marinescu and Balacescu. Professor Babes, who was born in 1854, studied medicine in Vienna and worked in the clinics of Langer and Rokitanski, on whose recommendation he was appointed assistant at the Budapest anatomicopathologic institute from 1872 to 1888. In 1881 he was appointed lecturer on pathologic histology. Then he went abroad and worked with Professor Ziemssen of Munich, Arnold of Heidelberg, Recklinghausen and Waldeyer of Strasbourg, Koch and Virchow of Berlin and Pasteur and Cornil of Paris. In the latter's clinic in Paris, in conjunction with Professor Cornil, Babes edited the first textbook of bacteriology under the title *The Bacteria*. Professor Cornil recommended Babes to a professorship at Bucharest university, to which he was invited in 1888. In that year the legislative corporation voted a special law which accorded the necessary sum for the foundation and erection of a pathologic and bacteriologic institute, which was opened under the direction of Babes in 1889. This institute also served for teaching experimental pathology, bacteriology and pathologic anatomy. He wrote about 700 treatises. His greatest works are *Atlas der pathologischen Histologie des Nervensystems* (Berlin, 1892), *Traité de la rage* (1912) and *Original Researches on Pellagra in Rumania* (1915).

Marriages

LEE EDWARD PARMLEY, Big Spring, Texas, to Miss Thelma Lowery of Winter Haven, Fla., in Fort Worth, February 24.

FRANK ALBERTUS MOORE BRYANT, Bronxville, N. Y., to Miss Janice James of Beverly Hills, Calif., April 22.

EDMUND S. LOCKHART, Nokomis, Ill., to Miss Wilma V. Showers Reiser of East St. Louis, March 1.

JOSEPH HALFORD PATTERSON, Broadway, N. C., to Miss Gaynelle Seawell of Greensboro, March 5.

THOMAS MORTON RAINES, Wakefield, Va., to Miss Alice Virginia Hill of Dendron, February 24.

HOWARD C. RUFUS, Ann Arbor, Mich., to Miss Hilda Myers of Lancaster, Pa., February 28.

HOMER DAVID HICKEY to Miss Marguerite Eilene Bacon, both of Chattanooga, Tenn., recently.

MORRIS B. PAYNTER, Southport, Ind., to Miss Mabel Kearns of Plainfield, February 2.

EARL WILLIAM ROLES to Miss Nannie Evans, both of East Orange, N. J., April 14.

WILBUR E. BURNETT to Miss Peyton Bolling Jones, both of Philadelphia, May 24.

CLAIR G. SPANGLER to Miss Lillian Slater, both of Reading, Pa., April 19.

Deaths

Ellis Fischel ☉ St. Louis; Washington University School of Medicine, St. Louis, 1908; associate professor of clinical surgery at his alma mater and formerly associate professor of surgery at the St. Louis University School of Medicine; chairman of the state cancer commission; member of the Southern Surgical Association and the American Radium Society; fellow of the American College of Surgeons; at various times on the staffs of St. Mary's, DePaul, Barnard Free Skin and Cancer, Jewish and St. Luke's hospitals; aged 54; was killed, May 14, in an automobile accident.

Edward Frost Parker ☉ Charleston, S. C.; Medical College of the State of South Carolina, Charleston, 1889; an Affiliate Fellow of the American Medical Association; past president of the South Carolina Medical Association; professor emeritus of ophthalmology and otolaryngology and formerly dean at his alma mater; served on the medical advisory board during the World War; fellow of the American College of Surgeons; aged 70; died, March 28, of cerebral arteriosclerosis and chronic myocarditis.

Edward Josiah Brown ☉ Minneapolis; Dartmouth Medical School, Hanover, N. H., 1879; an Affiliate Fellow of the American Medical Association; member of the American Academy of Ophthalmology and Oto-Laryngology; past president of the Hennepin County Medical Society; formerly member of the city and state boards of health; aged 87; died, March 15, of cardiac decompensation and arteriosclerosis.

Joseph Walter Mills, Owensville, Mo.; National University of Arts and Sciences Medical Department, St. Louis, 1913; member of the Missouri State Medical Association; county health officer; member of the city board of health; aged 56; died, March 1, in the Missouri Baptist Hospital, St. Louis, of edema of the lungs and postoperative hernia.

Charles Henry Leonard, Providence, R. I.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1868; member of the Rhode Island Medical Society; Civil War veteran; for many years in charge of vaccination of the city health department; aged 95; died, March 19, of arteriosclerotic heart disease.

John Ross Mitchell ☉ Joliet, Ill.; Northwestern University Medical School, Chicago, 1916; member of the Clinical Orthopedic Society, American Academy of Orthopedic Surgeons and the Radiological Society of North America; aged 50; died, March 17, in St. Joseph's Hospital, of diabetes mellitus and bronchopneumonia.

Frederick Herrick Aldrich, Belview, Minn.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902; formerly member of the state legislature, mayor and postmaster; served during the World War; aged 66; died in March of myocarditis, diabetes mellitus and streptococcal infection.

Stanley Edward Stroube, Livermore, Calif.; University of Tennessee College of Medicine, Memphis, 1914; fellow of the American College of Surgeons; served during the World War; on the staff of the Veterans Administration Facility; aged 46; was found dead, March 21, of carbon monoxide poisoning, self administered.

Duncan MacCalman, Baltimore; Baltimore Medical College, 1895; served during the World War; formerly connected with the U. S. Veterans Bureau; aged 73; associated from 1895 to 1901, and superintendent from 1898 to 1900 of the Maryland General Hospital, where he died, March 14, of carcinoma of the colon.

John Alexander Robinson ☉ New York; University and Bellevue Hospital Medical College, New York, 1899; member of the American Laryngological, Rhinological and Otolological Society and the American Otolological Society; on the staff of the New York Eye and Ear Infirmary; aged 61; died, March 24.

Wallace Nelson Brown, Watertown, N. Y.; University of Vermont College of Medicine, Burlington, 1890; Bellevue Hospital Medical College, New York, 1892; aged 72; died, March 17, in the St. Lawrence State Hospital, Ogdensburg, following a prostatectomy, of chronic myocarditis and arteriosclerosis.

Willoughby Carr Pendill, Huntington, N. Y.; Syracuse University College of Medicine, 1913; member of the Medical Society of the State of New York; served during the World War; formerly on the staff of the Huntington Hospital; aged 49; died, March 13, in Yuma, Ariz., of angina pectoris.

Charles Samuel McIntyre, Hastings, Mich.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1896; member of the Michigan State Medical Society; on the staff of the Pennock Hospital; aged 68; died, March 2, in West Palm Beach, Fla., of coronary thrombosis.

Ira Mesick Garrison, East Greenbush, N. Y.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1876; for many years health officer of East Greenbush and Schodack; aged 82; died, March 29, in St. Peter's Hospital, Albany, of pernicious anemia and uremia.

Le Verne Holmes, Manchester, Conn.; Boston University School of Medicine, 1904; veteran of the Spanish-American and World wars; served on the staff of the Manchester Memorial Hospital in various capacities; aged 58; died, March 26, in Scarsdale, N. Y., of coronary occlusion.

Benjamin Arnauld Smillie, Gilmore City, Iowa; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1903; member of the Iowa State Medical Society; secretary of the Pocahontas County Medical Society; aged 68; died, March 7, of coronary embolism.

Wayne McKnight Shirley, Carroll, Iowa; Rush Medical College, Chicago, 1905; served during the World War; past president and secretary of the Carroll County Medical Society; health officer; on the staff of St. Anthony Hospital; aged 57; was found dead, March 20.

John Winford Stevens, Nashville, Tenn.; University of Nashville Medical Department, 1900; member of the American Psychiatric Association; owner of the City View Sanitarium; aged 58; died, March 18, in St. Thomas Hospital of carcinoma of the colon.

William Whitfield White, Houlton, Maine; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1874; Jefferson Medical College of Philadelphia, 1878; member of the Maine Medical Association; aged 87; died, March 6, of pneumonia.

Carl Lorraine McCallum, Sapulpa, Okla.; University of Nashville (Tenn.) Medical Department, 1895; member of the Oklahoma State Medical Association; past president of the Creek County Medical Society; aged 59; died in March of septicemia.

Charles Joseph McGurren, Devils Lake, N. D.; Minneapolis College of Physicians and Surgeons, 1904; formerly secretary of the state board of health; on the staff of the Mercy Hospital; aged 64; died, March 11, of carcinoma of the sigmoid and liver.

Anthony Joseph Thomas, Easton, Pa.; Georgetown University School of Medicine, Washington, D. C., 1935; aged 30; died, March 12, in the Newark (N. J.) Eye, Ear and Nose Hospital of streptococcal meningitis, chronic mastoiditis and otitis media.

Peter Albert Sundbury, Holdrege, Neb.; Keokuk (Iowa) Medical College, 1894; past president and secretary of the Phelps County Medical Society; on the staff of the Holdrege Hospital; aged 71; died, March 17, of chronic nephritis and arteriosclerosis.

Homer Francis Peirson, Austin, Minn.; Rush Medical College, Chicago, 1895; past president of the Mower County Medical Society; for many years county coroner; aged 71; died, March 24, in St. Olaf Lutheran Hospital of cerebral hemorrhage.

Clarence S. Beals, Wyoming, N. Y.; University of Buffalo School of Medicine, 1903; health officer of the town of Middlebury and the village of Wyoming; aged 59; died, March 20, of chronic myocarditis, arteriosclerosis and chronic nephritis.

Charles Ignatius Proben, New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1890; Bellevue Hospital Medical College, New York, 1890; aged 74; died, March 21, of heart disease.

Garfield Ray Salsberry, Lyons, Ohio; Detroit College of Medicine, 1903; member of the Ohio State Medical Association; member and past president of the county board of education; aged 58; died, March 23, in an automobile accident.

John Nelson Tector, Englewood, N. J.; Bellevue Hospital Medical College, New York, 1892; served during the World War; formerly on the staff of the Englewood Hospital; aged 67; died, March 5, of coronary occlusion.

Emory James Rhoades, Walla Walla, Wash.; University of Colorado School of Medicine, Denver, 1911; served during the World War; aged 54; died in March at a local hospital following an operation for gallstones.

George Corlett Radcliffe, Peninsula, Ohio; Cleveland Homeopathic Medical College, 1898; Medical Department of Ohio Wesleyan University, Cleveland, 1901; aged 63; died, March 22, of cerebral thrombosis.

Charles Kirtland Stillman, Mystic, Conn.; Columbia University College of Physicians and Surgeons, New York, 1904; served during the World War; aged 58; died, March 22, of pulmonary tuberculosis.

William V. Russell, Dalton, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1909; also justice of the peace; aged 68; died in March in the Hamilton Memorial Hospital of pneumonia.

S. I. Sturges, Azle, Texas; University of Tennessee Medical Department, Nashville, 1893; aged 69; died, March 21, in a hospital at Fort Worth of cerebral thrombosis, hemiplegia and bronchopneumonia.

Lillis Adora Wood Starr, Los Angeles; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1891; aged 72; died, March 4, of injuries received in an automobile accident.

Ralston William Sleeter, Medford, Ore.; State University of Iowa College of Medicine, Iowa City, 1909; member of the Oregon State Medical Society; aged 55; died, March 9, of coronary disease.

Charles Basil Murray, New York; Bellevue Hospital Medical College, New York, 1887; member of the Medical Society of the State of New York; aged 74; died, March 30, of myocarditis.

William Wesley Earles, Seattle; Milwaukee Medical College, 1910; member of the Washington State Medical Association; aged 54; died, March 5, at Rochester, Minn., of hypertension.

Clarence Rupert Morss, Zumbrota, Minn.; University of Pennsylvania Department of Medicine, Philadelphia, 1908; aged 57; died, March 23, in Rochester, Minn., of carcinoma of the lung.

James B. Smith, Dunlap, Tenn.; University of Nashville Medical Department, 1896; aged 65; died, March 28, in the Pine Breeze Sanatorium, Chattanooga, of tuberculosis of the kidneys.

Charles Roscoe Smith, Livermore Falls, Maine; Medical School of Maine, Portland, 1897; member of the school board; aged 72; died, March 21, of carcinoma of the brain and left lung.

Nathan Ryno Smith, Baltimore; University of Maryland School of Medicine, Baltimore, 1886; member of the Society of American Bacteriologists; aged 74; died, March 30, of erysipelas.

M. H. Proudfoot, Rowlesburg, W. Va.; Starling Medical College, Columbus, 1884; formerly member of the state board of health; aged 77; died, March 21, of cerebral embolism.

Anna M. Jack, New Castle, Pa.; Woman's Medical College of Pennsylvania, Philadelphia, 1897; aged 67; died, March 15, at Greenville, Tenn., of sclerotic cardiovascular disease.

Peyton Stark Lewis, Richmond, Va.; Medical College of Virginia, Richmond, 1919; member of the Medical Society of Virginia; aged 48; died, March 9, of myocarditis.

Philip Henry Berlenbach, Richmond Hill, N. Y.; Long Island College Hospital, Brooklyn, 1891; aged 75; died, March 23, in the Mary Immaculate Hospital, Jamaica.

Nicholson Few Curtis, Dobbs Ferry, N. Y.; Western Reserve University Medical Department, Cleveland, 1912; aged 53; died, March 20, of cerebral hemorrhage.

Iver Stoland, Eau Claire, Wis.; Rush Medical College, Chicago, 1911; served during the World War; aged 53; died, March 8, of a self-inflicted bullet wound.

Joseph Amedce Girouard, Lewiston, Maine; School of Medicine and Surgery of Montreal, Canada, 1889; aged 74; died, March 1, of carcinoma of the stomach.

J. Webb McGehee, Baton Rouge, La.; Tulane University of Louisiana Medical Department, New Orleans, 1900; aged 62; died, March 8, of angina pectoris.

James H. Hylton, Table Rock, Neb.; Lincoln Medical College of Coter University, 1903; aged 66; died, March 2, at Elmwood of obstructive biliary cirrhosis.

William F. Ashley, Shaw, Miss.; Tulane University of Louisiana Medical Department, New Orleans, 1901; aged 72; died, March 22, of cardiorenal disease.

Emerson Sumers Porter, Columbus, Ohio; University Medical College of Kansas City, Mo., 1895; aged 67; died, March 8, of coronary occlusion.

William Lovett, Detroit; McGill University Faculty of Medicine, Montreal, Que., Canada, 1870; aged 85; died, March 19, of arteriosclerosis.

Sollis Runnels, Indianapolis; Chicago Homeopathic Medical College, 1887; aged 83; died, March 13, of angina pectoris.

Paul E. Redd, Richmond, Va.; Medical College of Virginia, Richmond, 1895; aged 65; died, March 27, of myocarditis.

Correspondence

THE USE OF ZINC SULFATE SOLUTION FOR THE PREVENTION OF POLIO- MYELITIS IN MAN

To the Editor:—In THE JOURNAL a year ago (June 26, 1937, p. 2182) we reported that 1 per cent zinc sulfate solution thoroughly applied to the olfactory mucosa in monkeys affords a high degree of protection against poliomyelitis virus instilled intranasally a month later. Because susceptibility returned in most of the monkeys when they were retested some months later, and the anosmia following the application of zinc sulfate solution in man seemed to be only of temporary duration (Peet, M. M.; Echols, D. H., and Richter, H. J.: The Chemical Prophylaxis for Poliomyelitis, THE JOURNAL, June 26, 1937, p. 2184), we suggested a field test to determine the value of this solution in preventing the disease in man. Opportunities to carry out such tests appeared a few months later in several eastern cities. The results of one of these has been recently reported (Tisdall and others: *Canad. Pub. Health J.* 28:523 [Nov.] 1937). It is not our purpose to comment on the results of this test except to say that we believe the authors do not in any way answer the important practical question whether zinc sulfate solution properly applied is of value in preventing the disease in man. Our chief reason for regarding this test as uninformative on this point is the fact that the figures given indicate that probably not more than 14 per cent of those sprayed were actually treated thoroughly enough to cover all of the olfactory area. From the observations of Peet, Echols and Richter, of Pentecost (*Canad. Pub. Health J.* 28:493 [Oct.] 1937) and of Hayden (*M. Clin. North America*, January 1938), which show that anosmia almost always follows a thorough application of zinc sulfate, it would appear that about 85 per cent of those sprayed in the Toronto test were not treated thoroughly enough to cover all of the olfactory area. We believe that this failure can be laid largely to the difficulties which attend the effective use of the special atomizer suggested by Peet, Echols and Richter. A simpler and probably more efficient method of covering the olfactory area has since been suggested by Shahinian, Bacher, McNaught and Newell (THE JOURNAL, April 16, p. 1254). Our purpose in this communication, however, is not so much to deal with the technic of applying the solution as to point out an important risk attending the application of zinc sulfate solution to the olfactory area.

To obtain protection the solution should probably be applied thoroughly enough to induce a temporary anosmia, and to maintain such resistance as may be afforded the application should probably be repeated as soon as the sense of smell returns. But while anosmia is probably an important index of sufficiently thorough treatment and the persistence of anosmia possibly evidence of continued resistance, no one wants such a functional effect to be lasting. While in children the sense of smell seems always to return within a few weeks, in adults it may be much longer in returning. We know of a few cases in adults in whom this function did not return until after periods of from two to four months. What is especially important is that recently we have learned of several cases in adults in whom the sense of smell has not yet returned after a period of more than six months. We do not know of any cases of lasting anosmia in children.

In adults the pain that immediately follows the application of the solution is apt to be more severe and of longer duration than in children. We believe that both the severity of the immediate reaction and the duration of the anosmia may be based on certain anatomic differences which influence the length of time the chemical may act on the olfactory mucosa. We understand that in adults the superior common nasal meatus tends to be much narrower and deeper than in children. A

very narrow cleftlike meatus would tend to hold solutions by capillary attraction. Such retention would naturally result in a more prolonged and uncontrolled drug action, resulting in more intense and prolonged pain and a more profound injury to the olfactory mucosa. These considerations, together with our recent observation that in some monkeys there is a rather severe exudative inflammation of the olfactory mucosa, associated with desquamation of epithelial cells, especially in animals examined from one to two days after treatment with 1.5 per cent zinc sulfate solution, prompts us to sound a word of caution against the further use of zinc sulfate in man until more is known about the mechanism underlying the protection in monkeys; also about the risk of inducing permanent anosmia in man.

The fact that susceptibility in monkeys generally returns after several months and the fact that children generally regain the sense of smell within two weeks seems to show that a 1 per cent solution of zinc sulfate (U. S. P.) can be applied to many persons without much risk of producing permanent anosmia. At the same time it is clear that this risk does exist and that it is greater in adults. It may prove greater in children than experience thus far seems to indicate if the induction of anosmia is made a criterion of successful treatment and theoretically an index of the duration of the protection afforded by zinc sulfate solution.

The risk of inducing a lasting anosmia may possibly be reduced if the zinc sulfate solution is followed within a few minutes by drops of physiologic solution of sodium chloride instilled by the Shahinian method. This would have the effect of reducing the length of time that a full strength solution of zinc sulfate would be permitted to act, should it tend to be held by capillary attraction in the superior common nasal meatus. At any rate the treatments should never be repeated more than necessary to induce and maintain anosmia nor should they be carried out with solutions containing more than 1 per cent zinc sulfate (U. S. P.). The use of local anesthetics should probably be avoided.

We shall appreciate greatly additional information bearing on the duration of the anosmia in man following the application of zinc sulfate solution. Such information will help us in answering the many inquiries that come to us. While we are continuing investigations on the mechanism of chemically induced resistance in monkeys, we appreciate that the full answer as to the practicability of such a measure cannot be obtained from experimental observations in animals. We wish therefore to urge physicians to transmit to us their individual experiences.

THE DOSAGE OF ANTITOXIN IN A CASE OF TETANUS

To the Editor:—In THE JOURNAL April 16, page 1271, appeared a case report by Cables and West entitled "The Amount of Antitoxin Used in a Case of Tetanus." They report that 3,460,000 units of antitoxin was administered over a period of forty-one days. The authors state that "with the modern methods of preparation of tetanus antitoxin it is possible to give large amounts of it without serum sickness," and that it is best to continue serum administration as long as any increased tonus of muscles is present.

Such a course would result in unwarranted deaths in a disease that already has a high fatality rate.

For twelve years I have had supervision and management of all tetanus cases admitted to the Los Angeles County Hospital, which averages about twenty-five cases annually.

In a previous publication (Vener, H. I.; Bower, A. G., and McKillop, J. E.: *Clinical Tetanus, a Study of 131 Cases, California & West. Med.* 39:6 [Dec.] 1933) it was emphasized that "regardless of the age of the patient, the sex, the average incubation period, the etiological factor or the site of injury, or with the amount of antitoxin given as an initial dose up to 100,000 units, the fatality rate was at least 50 per cent. Furthermore, that the greatest number of deaths occurred within the first three days of hospitalization, and that if a patient could be kept alive for a period of nine days following admission the chances for recovery were 90 per cent in his favor."

The cost of the antitoxin must be given careful consideration. At the market price prevailing last summer, the approximate rate per hundred thousand units was \$50. As a result, approximately \$1,700 worth of serum was given when \$125 worth would have sufficed. At the current market price, the cost of the antitoxin has been reduced, on an average, about one third.

During the past thirty-four months I have instituted at the Los Angeles County Hospital a regimen of management, with certain modifications, for the treatment of clinical cases of tetanus and have published a preliminary report (*Treatment of Tetanus, California & West. Med.* 48:3 [March] 1938). According to this report, and up to April 1, 1938, I have supervised a consecutive series of seventy-five cases, with twenty deaths, a gross fatality rate of 26.6 per cent. This contrast is rather significant when compared with the death rate prior to the current study of approximately 52 per cent. The lowered fatality rate included some patients who died within a very short period of admission, and in several instances they did not receive any antitoxin. Crediting as hospital deaths the nine cases in which death occurred within the first twenty-four hours of admission, there was a series of sixty-six cases with eleven deaths, a net fatality rate of 16.6 per cent. I advocate that, as soon as a diagnosis of tetanus is made, the case be considered as a surgical emergency and immediate treatment instituted.

Cables and West stress the fact that serum sickness appeared about nineteen days after admission, but still they continued to give antitoxin. This administration of serum as cited, for a period of nearly six weeks, should be condemned. In my experience the average hospital stay of a patient has been about three weeks. The total dosage of antitoxin administered, exclusive of the desensitizing doses, is 200,000 units per case.

In our present series, despite the refinement in preparation of antitoxin, and all precautions as to sensitivity tests, serum sickness has occurred, approximately, in 35 per cent of the cases. Serum sickness frequently accentuates the irritability of the patient and the spasticity of the muscles. Experience has demonstrated that such a condition is not due to a relapse. I feel that it is not necessary to continue serum therapy as long as the patient has spasms. This condition may often continue for two or three weeks and occasionally a little longer, but it is not an indication for continued therapy. Titration studies on the blood (Spooner, E. T. C., and Cole, Leslie: *The Treatment of Tetanus, with Observations on the Fate of Injected Antitoxin, Quart. J. Med.* 4:295 [July] 1935), following the intravenous administration of 200,000 units as a single dose, revealed that the antitoxin disappeared rather rapidly at first and then more slowly. However, at the end of seven days there still remained about 10 units of antitoxin per cubic centimeter and at the end of fourteen days there was from 3 to 5 units of antitoxin per cubic centimeter of blood.

Assistant Epidemiologist, Los Angeles
City Health Department.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

INTRADERMAL TREATMENT IN HAY FEVER

To the Editor:—What evidence is there that the intradermal method of treating hay fever by means of extracts of timothy pollen is as efficacious as the usual subcutaneous route? M.D., New York.

ANSWER.—Injections for hay fever are given either preseasonally, coseasonally or perennially. Preseasonal injections are usually given subcutaneously; in the perennial method, according to which injections are given all the year round, the subcutaneous method is likewise in general use. However, in the coseasonal method, in which injections are given during the hay fever season, the intradermal (intracutaneous) technic is employed by many. Vaughan in 1923 advocated subcutaneous injections during the season; but Phillips in 1926 and again in 1933 advised intradermal pollen therapy during the attack. Phillips reported 91 per cent satisfactory results in 322 patients who were given low dosages of appropriate pollen extracts intracutaneously. The maximum amount injected was 0.17 cc.; if more was injected the dose was divided. Permanent scars were thus avoided. Phillips pointed out that glycerin extracts, especially if concentrated, tend to be painful and to leave scars. Phillips had twelve general reactions in this series. His patients were given extracts of the pollens of Bermuda grass, careless weed, Russian thistle and others.

Thommen is strongly in favor of the intradermal method for coseasonal treatment. He points out, however, that only small amounts can be used with safety. Unger and Moore brought out a new extracting fluid consisting of 5 per cent dextrose with 0.5 per cent phenol; this is not irritating and is especially valuable in intradermal therapy.

Rackemann and others have shown definitely that intradermal injections of pollen extracts give much larger local reactions and are much more likely to cause constitutional symptoms than equal doses given subcutaneously. The epithelial tissues seem to have much more histamine or a histamine-like substance than the mesenchymal subcutaneous tissue; this histamine substance seems to be important in initiating allergic reactions.

It must be added that many other men have not found good results by either subcutaneous or intradermal treatment during the hay fever season. Most still prefer the preseasonal method, and the perennial method is becoming more and more popular.

HUMAN ANTITYPHOID SERUM UNDESIRABLE— PREPARATION OF RABBIT ANTITYPHOID SERUM

To the Editor:—Will serum made in the human body be all right for antityphoid agglutination work? How much vaccine should be given? At what titer must the serum be? What are the chances of getting a typhoid infection with a high titer? What technic should be used for building up a sufficient titer in the rabbit?

HUGH EARLE, Fulton, Ky.

ANSWER.—Antityphoid serum from human sources is not desirable for use in identifying unknown organisms. Chief among the objections to its use are the facts that: (a) The patient may have had a mild case of paratyphoid fever or may have been inoculated with T. A. B. or T. A. B. C. vaccine in the past and the injection of typhoid vaccine will raise the paratyphoid antibody titer, resulting in a serum containing mixed antibodies. (b) Some human beings fail to develop H (flagellar) agglutinins in response to infection or inoculation. The antiserum would therefore contain only O (somatic) agglutinins. H agglutination is commonly used for the differentiation of types of enteric organisms. *Bacillus typhi* and *B. enteritidis*, for example, have the same somatic antigen. (c) Somatic agglutinins produced in human beings fail to show the specificity that rabbit serums show and that might be expected from the known antigenic structure of the typhoid and paratyphoid bacilli. (d) High titers, i. e., 1:1,000 or more, are not commonly found in human serums. For these and other reasons, human antityphoid serums are of doubtful quality.

The agglutinin titer of serums from typhoid patients varies not only with individuals but with the day of the disease on

which the specimen is taken. It is reasonable to conclude from recorded data that the great majority of typhoid infections will, during the third week, show an H titer of 1:200 and an O titer of 1:100 or better. Titers of 1:650 are not uncommon and titers of 1:1,000 may be regarded as exceptionally high.

Antiserums may be prepared in rabbits by the inoculation of twenty-four hour cultures of living motile typhoid bacilli. The suspension is ordinarily prepared by washing up the growth on agar with sterile saline solution and adjusting to a concentration of approximately 500 million per cubic centimeter. The following inoculation procedure has been found satisfactory: 0.5 cc. intraperitoneally, 1 cc. intraperitoneally, 0.5 cc. intravenously, 1 cc. intravenously, 2 cc. intravenously. The injections are made at five day intervals if the animal does not lose weight. If weight is lost, it is best to repeat the immediately preceding injection and then continue as before. Five days after the last injection a small amount of blood is removed from the ear for testing. If the titer is satisfactory the animal is exsanguinated from the heart. Such a serum should have a titer of 1:5,000 or better. It will contain both H and O agglutinins. Monospecific O antiserums may be prepared by growing the typhoid bacilli on phenol (1:1,000) agar. Monospecific H antiserums may be prepared by absorbing the mixed antibody serum with O antigen, i. e., bacilli grown on phenol agar, and leaving only the H agglutinins remaining.

PRECOCIOUS DEVELOPMENT IN CHILD AFTER ESTROGENIC TREATMENT FOR GONORRHEA

To the Editor:—A girl, aged 5, was infected with gonorrhea when she was 3. She was treated by a child specialist for one year with theelin, 1,000 units weekly. The family then moved to another city and, the child being still infected, she was given amniotin and vaginal treatment and has had that for a year now. She was recently brought to me, with the smear still positive and with definite signs of precocious development of the breasts and a slight pubic growth of hair. Could this development be from the long continued use of the endocrine treatment or is it something else? I have changed my method of treating childhood gonorrhea but would appreciate any information you would give me concerning this case.

J. O. HAMPTON, M.D., Blackfoot, Idaho.

ANSWER:—The treatment of gonorrheal vaginitis in the child before puberty has always been recognized as difficult and unsatisfactory. It is known that, in the immature girl, gonorrheal infection is limited to the vaginal mucous membrane and seldom involves the undeveloped accessory glands of the cervix. It is also known that in the adult woman gonorrhea rarely involves the vaginal mucous membrane and, if present, is of short duration.

The reason for these differences in localization is that in children the vaginal mucous membrane is thin and delicate, consisting of from four to eight layers of epithelial cells, with many rugae or folds. Gonococci flourish on this delicate mucous surface and eventually penetrate into the subepithelial spaces, where they become resistant to local treatment.

Edgar Allen (*J. Morphol.* 46:479 [Dec. 5] 1928) demonstrated that estrogen administered to immature monkeys increased the number of vaginal epithelial layers with cornification of the surface epithelium, a condition characteristic of the adult vaginal mucosa.

R. M. Lewis (*Am. J. Obst. & Gynec.* 26:593 [Oct.] 1933) reasoned that, if he could change the immature vaginal epithelium of the child to the adult type by the use of estrogen, he could eliminate the gonococcal infection. That this can be done has been proved many times, and it forms the basis for the estrogenic treatment of gonorrheal vaginitis in children.

Lewis and Adler (*THE JOURNAL*, June 13, 1936, p. 2054) thought originally that the mere histologic change involved in temporarily converting the thin vaginal mucosa of the child to the far thicker and partly cornified structure of the adult adequately explained the destruction of the invading gonococci. Further studies have convinced them that the curative result is in all likelihood due not to the histologic change alone but to a striking change in the reaction of the vaginal secretions. The nearly neutral reaction, normal in childhood, changes to acidity, which always accompanies temporary maturation of the mucosa.

It is the present belief that the treatment of gonorrheal vaginitis in children by the use of estrogenic vaginal suppositories is more effective than is the intramuscular administration of estrogen.

It is stated that "the child was given 1,000 units of theelin weekly for one year." The method of administration is not described. This was later followed by amniotin suppositories for one year. The frequency of treatment and the amount used is again not stated. The vaginal smears are still positive for

gonococci and the child has definite signs of precocious development of the breasts and a slight growth of pubic hair.

The child has had more than sufficient theelin to produce development of the adult type of vaginal mucosa with cornification of the epithelial layer, if it has been properly administered with regard to time and concentration. The evidences of precocious development are almost surely due to the prolonged administration of estrogen. With this patient it was correct and justifiable to discontinue the estrogen.

It seems best in this case to use nonestrogenic treatment now. Sulfanilamide might be tried. If other measures fail, perhaps after six months estrogen suppositories (1,000 international units) inserted each night for thirty days might again be tried. Smears should be examined to check success or failure.

FAMILIAL PERIODIC PARALYSIS

To the Editor:—About five years ago a man on lying down in bed, especially if he was to lie on his back, would at times hear a roaring in his ears, which was accompanied by absolute inability to move any muscles with the exception of his eye muscles and the muscles of his tongue. The feeling would wear away in a few seconds and entirely disappear. If during this time while the symptoms were present some one should lift his arm or shift his body in any way the symptoms would immediately cease. Physical examination and all laboratory reports were negative. Within the last three months two additional patients have complained of practically the same syndrome. One patient states that the syndrome is present in whatever position he lies and can be dissipated only if he is able to get his tongue between his teeth so that he can bite it. The other patient states that the syndrome comes on only as he is awakening from sleep. On awaking he finds himself unable to move. I am unable to account for this group of symptoms and any information that you can offer will be appreciated.

M.D., Massachusetts.

ANSWER:—Paralysis of the voluntary muscles coming on suddenly and disappearing with equal rapidity occurs characteristically in familial periodic paralysis, a rare disease, usually hereditary in character. Although most of the attacks begin in childhood, it is not uncommon for the onset to be delayed until the third decade of life. Often attacks occur early in the morning, just as the patient is awakening, although there may be prodromal symptoms the day before. Sweating often accompanies the paralysis, which reaches its maximum within a few minutes. The muscles supplied by the cranial nerves are not ordinarily affected. The tendon reflexes are lost during the attack, together with the electrical excitability of the muscles to both faradic and galvanic stimulation. There is a great variation in the frequency of the attacks, and patients are known to have attacks as often as every four or five days, particularly in winter.

The disease was described by Westphal and Oppenheim in 1885 and its hereditary character by Goldflam in the same year. The best recent account in English is by T. K. MacLachlan (*Brain* 55:47 [March] 1932). There is no treatment known which is effective either in preventing this disease or in shortening its course. It would be unusual for any physician to have two cases, both without hereditary factors. A further investigation is indicated along this line, as well as a more accurate description, particularly with regard to reflexes and electrical tests during a period of paralysis.

HOME SALTED PORK

To the Editor:—People of Italian extraction here are fond of preserved pork, which they preserve themselves from fresh pork. The meat is first salted for some time and then fresh salt and black pepper are added and the meat is wrapped up in waxed paper and kept in the cellar. While it is in the cellar a greenish mold develops almost invariably on the outside of the meat, which I don't see on the commercial type put out by the large packing concerns. Is there any danger from these molds? Could anything be added to the salt and pepper to prevent their formation, and if so what? Since this meat is eaten raw, how long a time should elapse, to be reasonably safe from trichinosis, before the meat is eaten? The meat is not ground but trimmed from so-called butts and sausage is made from the trimmings. The local name is "longetta," although other classes of Italian people refer to it as "capo-collo."

M.D., Pennsylvania.

ANSWER:—There is no evidence that the molds on this meat are dangerous to health. No safe material can be added to salt and pepper to prevent the formation of molds. The large commercial packing concerns make a product called capicola. The pork in this product is cured for twenty-five days in 3 per cent salt at from 36 to 38 F. It is then stuffed in casings and smoked for two days at 90 F., after which it is held for twenty-five days in a drying room at 52 F. Trichinella is not reported to survive this process. In answer to the third question, the home prepared meat could not be considered safe, since under the conditions mentioned Trichinella might survive for many weeks.

NUMOTIZINE AND PLASTERS IN RESPIRATORY DISEASE

To the Editor:—What is the value of medication applied in the form of ointments or plasters to the chest wall in upper respiratory infections, acute bronchitis and pneumonia? The chief constituents of such—judging by the odor—are guaiacol, oil of pine needles and menthol. Some are offered by reputedly ethical pharmaceutical houses; more of them are sold under a patent name (e. g., Numotizine) to the public. Is there sufficient absorption of guaiacol through the skin to make its use in this fashion justifiable? Do any of the other constituents exert a more favorable action when applied this way? Is there any action of medicaments of this description other than counterirritation? M.D., Illinois.

ANSWER.—Numotizine is the name applied to the preparation known for many years under the name "Pneumo-Phthisine." It is stated to contain guaiacol 2.6 parts, solution of formaldehyde 2.6 parts, quinine 2.6 parts, methyl salicylate 2.6 parts and creosote 13.02 parts in a glycerin and aluminum silicate (kaolin) base, to make 1,000 parts. From this formula it appears that the preparation is a clay poultice (similar to the cataplasm of kaolin of the National Formulary) to which has been added guaiacol, formaldehyde, quinine, methyl salicylate and creosote.

The Council on Pharmacy and Chemistry considered this preparation more than twenty-five years ago and declared it inadmissible to New and Nonofficial Remedies because the therapeutic claims that were made for it were considered unwarranted, exaggerated and absurd, because the label on the trade package constituted an indirect advertisement to the public and because the name "Pneumo-Phthisine" was not descriptive of the composition of the mixture. Although poultices are often employed for maintaining rubefaction of the chest in patients with bronchitis or bronchopneumonia, there appears to be no evidence that Numotizine is an efficient means of producing the systemic effects of the various drugs which it contains. Incidentally, the advertising matter for Numotizine that is in the Council's files contains no recommendation for the use of the product as a treatment for pneumonia.

EXCESSIVE LIBIDO IN MAN

To the Editor:—A man, aged 53, clever and successful in business, has always been so oversexed that he has as many as twelve orgasms during one intercourse. If he misses intercourse for more than three days he cannot do justice to his business, becomes nervous and always feels much better after intercourse. He has been suffering from hyperinsulinism for the past five years. He had a goiter (exophthalmic) removed twelve years ago and has taken thyroid extract ever since. When he takes too much his sex capability increases. He feels that at his age so much libido is dangerous to his health. What can be done for him? Would cauterization of the verumontanum be indicated? Would prostatectomy affect his business ability? M.D., Michigan.

ANSWER.—This is probably a mild form of satyriasis and in some cases, in which the verumontanum is enlarged and congested so that it continually touches and irritates the urethral mucous membrane, cauterization may effect a cure. Otherwise, no remedy has thus far been found to alleviate the condition, though at times large doses of bromides may help to reduce the sexual passion. Prostatectomy will have no influence on the condition and should be performed only when the usual urologic indications for the operation exist.

CONTROLS IN SCHICK AND DICK TESTS

To the Editor:—Please answer the following: 1. What is the significance of a positive Schick control test? 2. The significance of a positive Dick control test? 3. When the Schick test and Schick control are positive in patients who have never received active immunizations are these patients to be considered immune to diphtheria or should they receive a course of active immunization? 4. When the Dick test and Dick control are positive in patients who have never received active immunizations, are these patients to be considered immune to scarlet fever or should they receive a course of active immunization? 5. Will a positive Schick control test persist throughout the life of an individual? 6. Will a positive Dick control test persist throughout the life of an individual? In answering these questions kindly quote the source of information. M.D., New York.

ANSWER.—1. A positive Schick control test is said to indicate sensitivity to the nonspecific protein in the Schick test material rather than susceptibility to diphtheria toxin.

2. There is no routine Dick control test (Rhoads, P. S.: *Skin Tests and Immunizations Against Scarlet Fever and Diphtheria*, THE JOURNAL, July 18, 1931, p. 153).

3. It is much safer to disregard a positive control test when testing persons for the first time, because it will be found that many so-called pseudoreactions will have become negative after immunization. If on retest following an adequate immunizing course the control test is as large, as bright and as indurated as the test made with unheated toxin, it is probably safe to call the retest a pseudoreaction (personal communication from the Dicks).

4. The Dicks advise against the routine use of a control test because the protein in Dick material is minimal. Pseudoreactions are so rare that the use of heated toxin or diluted medium control solution would lead to considerable confusion. Rarely a control may be useful in retesting persons who still have positive Dick tests after receiving much more toxin than the regular series of doses. In such persons, if heated skin test solution or medium control gives a test as large, as bright and as indurated as one made with regular Dick toxin, the Dick reaction may be a false positive. Such reactions are extremely rare.

5. A positive Schick control test will not always persist throughout the life of an individual. Many disappear after active immunization.

6. See answer 2.

PLACENTAL BLOOD TRANSFUSION

To the Editor:—In the editorial in THE JOURNAL, April 2, on "A New Source of Blood in Transfusion," you gave the formula used by the Moscow Institute of Hematology for a preservative of placental blood. You do not mention in what quantities it is to be added to the blood. Please give me this information if available. Also please let me know where I can get more detailed information concerning this subject, especially concerning the use of this blood in malignant conditions.

EDWARD J. MARTONE, M.D., Brooklyn.

ANSWER.—The formula of the diluting fluid recommended by the Moscow Institute of Hematology is as follows:

Sodium citrate	5.00 Gm.
Sodium chloride	7.00 Gm.
Potassium chloride	0.20 Gm.
Magnesium sulfate	0.004 Gm.
Distilled water	1,000.00 cc.

Blood is diluted with an equal quantity of fluid. This diluting fluid has been tried at the Blood Preservation Laboratory of the Cook County Hospital, Chicago, and has not been found superior to 70 cc. of the 2.5 per cent sodium citrate in physiologic solution of sodium chloride, which has been found adequate for the prevention of clotting of 500 cc. of blood.

There is probably no special advantage in the employment of blood transfusion in the treatment of malignant conditions excepting to the extent to which it may make it possible to tide a person over an operation.

POSSIBLE CONVULSIONS FROM DIPHTHERIA TOXOID

To the Editor:—A girl, aged 6, seen in consultation was in severe tetanic convulsions a day after her second diphtheria toxoid injection and had a severe local reaction. The day of the injection she had fever. Two weeks previously she had received a burn but no other injuries. She had never had convulsions previously. She was treated by the family physician by a hot enema and chloroform and gradually relaxed after one hour of a convulsive state. I did not see her subsequently but heard that she had a high fever for a week and then recovered. No other symptoms developed. Physical examination at the time of the convulsions was negative. The convulsions appeared similar to those seen in tetanus. What is your opinion as to the cause of the convulsion? M.D., New Mexico.

ANSWER.—Although the possibility of tetanus infection associated with the burn might be considered, it does not seem to offer the correct explanation. The convulsions after the second dose of toxoid might be attributed to reaction, which was in the nature of an anaphylactic shock. Could not "the high fever for a week" be assigned to the "severe local reaction"? Severe local reactions after toxoid injections are not extremely rare. Constitutional reactions in older patients are fairly common.

PASSAGE OF TEST MEALS—INTESTINAL STASIS

To the Editor:—1. What is the normal length of time required for the passage of the barium sulfate meal through the gastro-intestinal tract? 2. Please discuss intestinal stasis and its treatment.

T. K. LEWIS, M.D., Birmingham, Ala.

ANSWER.—1. The time for passage of a barium sulfate meal through the gastro-intestinal tract will vary with the type of meal employed. A protein barium meal causes slight delay, a dextrose meal a moderate delay, and an olive oil meal a delay of about five hours. The times quoted below are for a standard water barium meal which consists of 5 ounces (150 Gm.) of barium sulfate and from 3 to 5 ounces (90 to 150 cc.) of water. The stomach empties in two hours and occasionally in from two and one-half to three hours, the small intestine in from two to four hours. Usually at four hours the head of the barium column enters the cecum, at the hepatic flexure of the colon in from six to seven hours, and at the splenic flexure in eight hours. Filling of the sigmoid is variable and may be between the ninth and the seventeenth hour. Usually at the

end of twelve hours the barium is evenly distributed from the cecum to the middle of the sigmoid. After twenty-four hours the largest part of the barium has reached the lower sigmoid and rectum and is evacuated.

2. This question is vague. Stasis may be acute or chronic and involve the small or large bowel or both. As the reply would be lengthy, reference should be made to Bassler's "Disease of the Intestines and Lower Alimentary Tract." It contains an excellent chapter on intestinal stasis in all its phases.

TAPEWORMS IN FISH—EFFECT OF KIPPERING AND SMOKING

To the Editor:—Have any of the fish of the state of Washington been known to harbor fish tapeworm? If so, does kippering and smoking kill these parasites?

M.D., Washington.

ANSWER.—No authentic record is known of the occurrence in the flesh of the fish of the state of Washington of the bladder worm or larval stages of the fish tapeworm, *Dipyllobothrium latum*, of man. However, a larval stage of an unknown fish tapeworm does occur in the flesh of trout and landlocked salmon in Washington, but the adult stage of this worm probably occurs normally in some fish-eating wild mammal. The process of kippering as ordinarily used does not kill the larval stages of the fish tapeworm in the flesh of the fish. It is reported that saturated brine applied for more than a month will destroy the larvae, provided the flesh is completely permeated by the brine. Larger fish and those with skins on are less readily penetrated than smaller ones. Smoking of fish as ordinarily carried on does not destroy the infective bladder worms in the flesh of the fish. The process of hot smoking if carried on for an hour or more at 75 C. is reported to destroy these larval stages.

BLADDER INJURY AFTER HYSTERECTOMY

To the Editor:—What may cause the bladder wall to become thin like tissue paper? Can you furnish any statistics on the percentage of bladder injuries following complete hysterectomies in the presence of so-called pus tubes?

M.D., Alabama.

ANSWER.—It is difficult to offer any explanation as to the thinning out of the bladder wall. Unfortunately it is impossible to quote any statistics regarding the percentage of bladder and ureteral injuries following complete hysterectomies. This is a subject that would be of great interest to the surgeon and should be reported in order that the newer generation of surgeons may appreciate the need for care as regards the ureters when doing pelvic surgery. It seems certain that these injuries do take place far more often than is usually recognized.

NO RELATION BETWEEN GARTERS AND CORONARY DISEASE

To the Editor:—There is a rumor that the wearing of men's garters will predispose to circulatory disturbances and in time lead to coronary trouble. I have never seen any evidence to support such a rumor. Is there anything in medical literature that shows a causal relationship between the wearing of men's garters and the disturbances I have mentioned?

WILLIAM J. TANNENBAUM, M.D., Chicago.

ANSWER.—No evidence has been obtained nor any reports found in the literature that the wearing of men's circular adjustable garters predisposes to coronary disease. If in a nonadjustable garter the pressure was great and distributed over a narrow area, the venous pressure distal to the constriction would be increased and there might be an aggravation of pre-existing varicose veins.

DANGERS OF INTRAVENOUS THERAPY

To the Editor:—Dr. Joseph K. Narat's comment on page 1387 of THE JOURNAL, April 23, regarding the possibility of harm in the indiscriminate use of vitamin B₁ preparations (thiamin chloride) ought also to call for a comment on the indiscriminate use of the intravenous method of administration. The spectacularity of the intravenous route seems to be so fascinating that it is being used in an overwhelming number of instances when it is not necessary and in plenty of instances in which it is harmful. When a therapeutic agent acts perfectly well by the oral route, why court trouble by throwing it into the circulation? The number of emergencies in which the intravenous route is the only possible method of administration for vitamin B₁ hydrochloride, and countless other therapeutic agents is negligibly small. The throwing of a substance of which our knowledge is incomplete into a circulatory situation of which our knowledge is also incomplete brings about a combination out of which any reasoning person would anticipate trouble beforehand. The intravenous route should be limited to such aid as cannot be administered otherwise or to emergencies in which the possible danger is less than that of delay.

NATIONAL BOARD OF MEDICAL EXAMINERS SPECIAL BOARDS

Examinations of the National Board of Medical Examiners and Special Boards were published in THE JOURNAL, June 4, page 1947.

North Dakota January Examination

Dr. G. M. Williamson, secretary, North Dakota State Board of Medical Examiners, reports the oral, written and practical examination held at Grand Forks, Jan. 4-7, 1938. Ten candidates were examined, eight of whom passed and two failed. Four physicians were licensed by reciprocity and two physicians were licensed by endorsement after an oral examination. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Colorado School of Medicine.....	(1932)		76.3
Loyola University School of			77.5
Rush Medical College.....			75.7
University of Minnesota Med	(1928)		80.5
University of Buffalo School of Medicine.....	(1932)		77.4

Book Notices

Diseases of Women for the General Practitioner. By Paul Titus, Obstetrician and Gynecologist to the St. Margaret Memorial Hospital, Pittsburgh. National Medical Monographs. Edited by Morris Fishbein, M.D. Cloth. Price, \$3. Pp. 320, with 55 illustrations. New York: National Medical Book Co., Inc., 1937.

This new member of the national medical monograph series is all that its name implies. It is simply, clearly and tersely written, presenting the whole subject of gynecology from the point of view of the general practitioner. Special emphasis is laid on accurate and early diagnosis, especially in the sections on carcinoma of the cervix and uterus and in the chapter on ectopic pregnancy. Operative procedures and microscopic pathology are properly omitted. The office treatment of ambulatory patients is emphasized, since, as the author states, "the greatest bulk of gynecologic practice is nonoperative." The introductory chapter describing the necessary supplies and instruments is excellent. The chapter on anatomy and physiology is simply and clearly written, but it is to be regretted that the author has seen fit to describe "rhythmic birth control" as factual and accurate. It is hoped that in the succeeding editions the author will place more emphasis on the relationship of the general physical condition to gynecologic problems, and that routine complete physical examinations will be stressed; that hypothyroidism will be mentioned in connection with the discussion on menorrhagia, since this is one of the most common etiologic factors; that the recommended use of Goodell dilators be omitted; and, finally, that the section on anesthesia carry a statement on some type of anesthesia other than the combination of rectal anesthesia, nitrous oxide and ether. In these days when ethylene, cyclopropane and other inhalation anesthetics give such safe and satisfactory results, it seems unnecessary to many to use a combined routine as recommended by the author. The chapter on sterility and its management is an excellent summary of the present day position and management of the sterile couple and can serve as a perfect guide for the general practitioner. The illustrations are adequate. All in all, this volume is an excellent textbook on nonoperative gynecology and is to be highly recommended to every general practitioner.

Elements of Chromotherapy: The Administration of Ultra-Violet, Infra-Red and Luminous Rays Through Colour-Filters. By R. Douglas Howat, L.R.C.P., L.R.C.S., L.R.F.P.S. With foreword by Sir Henry Gauvain, M.D., M.Chir., F.R.C.S. Cloth. Price, 8s. 6d. Pp. 106, with 21 illustrations. London: Actinic Press, Ltd., 1938.

This small book deals with the use of visible and invisible light rays through colored filters. There are chapters devoted to history, physics, erythema, action on bacteria, filters, lamps, technic and clinical observations. The author advocates the use of visible light through colored filters and makes many extravagant claims for the value of such radiations. Because of the fact that practically all modern experts in light therapy have considered that the use of colored lights can have no other effect on the human body than a psychic one, and because a noted authority on the physics of light, W. W. Coblentz of the Bureau of Standards of the United States government and member of the Council on Physical Therapy of the American Medical Association, has said "If the rays in the visible spectrum have any special therapeutic action, it remains to be determined," this textbook was reviewed with considerable care to determine whether the author had any new material to offer which might alter the generally accepted views on the subject and might justify his statement that chromotherapy was of value.

On superficial examination of the author's chapter on the action of color rays on bacteria, the impression is obtained that a rather imposing array of direct quotations has been presented

to support the author's views. However, when one carefully checks the brief bibliography which has been appended to the book, it is found that a number of the sources of references have not been given and that those that are given are not in any sense new and advanced ideas but on the contrary are extremely antiquated. For example, in the chapter cited which deals with the action of color rays on bacteria, the references that were given were dated 1877, 1904, 1858, 1883, 1879, 1889 and 1903. Such outdated material, all of it over 25 years of age, of course merits no serious consideration in a modern textbook and is of interest only from a historical standpoint. A check of the bibliography for the entire book shows that twenty-one of the forty-five references are articles written more than twenty-five years ago. The author bases his contentions on such obsolete material and on twenty-five sketchy case reports, all of which are presented in a highly unscientific manner. Typical of these case reports is the first one, which describes the treatment of "acidity" by application of a "red filter over epigastrium for fifteen minutes." The author reported that after a dozen treatments the patient "was absolutely free from symptoms and declared that she had never felt so fit."

The reviewer feels that it is such unscientific outmoded presentations which hamper the rapid growth of an extremely important field of medicine. The reading of such books creates in the mind of the average physician an unjustified critical attitude toward the entire field of physical therapy. The wide distribution of this book will probably hamper rather than aid the cause of physical therapy. The reviewer is rather amazed that a medical man could write such an unscientific textbook and that one so famed as Sir Henry Gauvain should be willing to lend his name to its publication. This textbook is not recommended.

Religion and Medicine of the Gã People. By M. J. Field. Cloth. Price, \$6.50. Pp. 214, with 31 illustrations. New York, London & Toronto: Oxford University Press, 1937.

The Gã people occupy parts of the Gold Coast region of western Africa, and the present volume is the result of a number of years of studies of the tribe by the author. The work gained the author a doctorate at the London University. Of its three parts the second deals with the principles and practice of medicine (and magic). These are almost wholly conditioned by the basic concepts by the Gã of the human being. This they hold is compounded of three entities—the *susuma*, or personality, spirit or soul; the *kla*, corresponding to life, and the material *body*. On the complex actions and interactions of these principles, and on the influences on them of spirits and witches, are based the conceptions and treatment of all disorders the cause and course of which are not plainly obvious. A chapter of the book deals with interesting hysterical manifestations among the people and with mediums, another with the medicine men and the means they use for curative purposes. In finding the causes of disease, diagnosis, prognosis and treatment there is an occasional spark of common sense, but the essentials are involved thaumaturgic ideas and practices, all of which to a medical man among ourselves is interesting mainly as a suggestion of what may have been the views and practices among our own faraway ancestry.

Traumatismes de l'oreille. Fractures du rocher—coups de feu de l'oreille, commotions labyrinthiques, expertises en otologie. Par J. A. Ramadier, oto-rhino-laryngologiste de l'Hôpital de la Pitié, et R. Causse, assistant d'oto-rhino-laryngologie des hôpitaux de Paris. Paper. Price, 45 francs. Pp. 150, with 15 illustrations. Paris: Masson & Cie, 1937.

This excellent monograph presents the subject of trauma to the auditory apparatus in detailed, clear and concise fashion. Most of the text is based on the authors' own experience, yet the conclusions are drawn only after due consideration of the opinions of other observers. The subject matter is aptly divided into five sections: (1) trauma to the external ear, the drum and the tympanic cavity; (2) fractures of the auricular skeleton; (3) injury by firearms; (4) commotio labyrinthi, and (5) medicolegal aspects. Thus every phase of the topic is covered. The authors attempt to group the symptoms and diagnostic signs in such a fashion as to make the indications for treatment clear. Yet it is conceded that while this may look well on paper, in actual practice one may find that certain cases overlap and do not readily fall within the given classification. However, the method is a good one since it brings to the fore the cardinal principles

on which safe conduct of the case depends. The discussion of commotio labyrinthi is an interesting one and the authors take great pains to offer every possible bit of advice that may be useful in distinguishing the simple subjective type which gets well spontaneously from the type in which there are definite objective manifestations. In the chapter on the medicolegal aspects of trauma the authors discuss thoroughly the questions of degree of disability, prognosis and malingering and describe in detail the numerous tests. Even true and false tinnitus are given attention. The book is adequately illustrated by reproductions of histologic sections and roentgenograms, the value of which is greatly enhanced by the accompanying explanatory diagrams. In the chapters on surgical treatment one finds Ramadier quite at home, since his approach to the petrous apex by way of the carotid canal is now a well accepted procedure and is in this connection modified to meet the conditions. It is safe to say that this little volume will be well appreciated by otologists as well as general surgeons who are interested in traumatic surgery.

Alkali Disease or Selenium Poisoning. By Alvin L. Moxon. South Dakota State College of Agriculture and Mechanic Arts, Agricultural Experiment Station, Department of Experiment Station Chemistry. Bulletin 311. Paper. Pp. 91, with 26 illustrations. Brookings, S. D., 1937.

Although, as the author points out, the term "alkali disease" is essentially a misnomer, it remains in use and probably will be retained to designate the specific type of selenium poisoning to which it was originally applied. This monograph contains an excellent brief historical review of the development of knowledge of this disease and includes an interesting quotation suggesting that Marco Polo might have referred to alkali disease. The subsequent portion is devoted principally to the study of the disease in live stock and poultry, including a considerable number of interesting original experiments. There is little reference to the selenium problem so far as it might affect human beings but the author concludes that in certain sections the selenium problem has proved a serious handicap to agricultural development. This study serves as a useful addition to the rapidly increasing literature on selenium poisoning.

Therapie der Tuberkulose. Herausgegeben von Prof. Dr. J. Berberich und Dozent Dr. P. Splro. Bearbeitet von J. Van Assen et al. Bände I und II. Paper. Price, 25 florins per set. Pp. 324, with 11 illustrations; 327-845, with 3 illustrations. Leiden: A. W. Sijthoff's Uitgeversmaatschappij N. V., 1937.

The contributions of investigators of tuberculosis during the past decade has reflected itself in new views on therapy, especially the view that tuberculosis is not a disease of an individual organ or organ system but of the organism as a whole, which has led to the necessity for treating the tuberculous human being. The desire of the practitioner to possess such an encompassing summary, which even the specialist of best intentions cannot keep abreast of today because of the extensiveness of the field, inspired these volumes. The first volume concerns itself with the general problems, the second with special fields of tuberculosis therapy. Collaborators from many different countries have made the volumes diversified and added materially to their value. A critical sketch of therapy in modern times is presented as the introduction by the master of therapy in tuberculosis, Prof. Albert Fraenkel of Heidelberg. Modern phthisiology and phthisiotherapy are characterized by the transition from empiric intuition to pathologic-clinical knowledge. The chapters in volume I include the biology and determination of the tubercle bacilli; immunity, including the natural and specific immune factors and the influence of nonspecific stimulants on specific immune processes (antigens and antibodies are discussed); the pathogenesis, the morphology and the allergic relations of the healing processes in tuberculosis; a chapter on the anatomic and experimental observations with therapeutic tests (animal); control of the course of tuberculosis; therapy by roentgenograms; tuberculin diagnosis; tuberculin therapy; protective immunization with tuberculin and BCG; tuberculosis as a chronic disease and the social hygienic treatment, and chemotherapy and vocational therapy. Volume 2 is introduced by a consideration of tuberculosis of the upper air passages followed by chapters on the therapy of pulmonary tuberculosis, surgery of pulmonary tuberculosis and the therapy of miliary tuberculosis. The organic systems are further considered as

cardiac and circulatory, gastrointestinal, lymph glandular, bone and joint, and so on, while lymphogranulomatosis, tuberculosis and diabetes mellitus are appropriately considered. The therapy of tuberculosis of childhood and of the aged is not neglected, and finally pregnancy, and psychology and psychotherapy are discussed. A valuable feature is the extensive bibliography at the end of each chapter, where it is readily accessible to use if desired. The list of notable collaborators attests the high quality of the contents, which include, besides the authors, Ernst Brieger, Albert Fraenkel, Julius Hollo of Budapest, Walter Pagel, Arvid Wallgren of Gotenburg and others. The volumes are paper covered, well printed, substantially bound, and suitably illustrated. There is an author and subject index at the end of volume 2. For those who are able to read German fairly fluently, these volumes should make a valuable addition to a practical library, although—and this is no criticism—heavily flavored with European views. The specialist in internal medicine and tuberculosis and the student of medicine will find much valuable information in these volumes which, though stressing therapy, do not do so at the expense of information on tuberculosis in general but weave therapy into the picture based on fundamental knowledge of tuberculosis of the newer types. It is refreshing to admit that there is a comprehensive textbook which could be critized by the exacting investigator but which contains so much valuable material that it might be then signified as possible individual prejudice. The volumes merit an extensive circulation.

Digestive Tract Pain; Diagnosis and Treatment: Experimental Observations. By Chester M. Jones, M.D., Assistant Professor of Medicine, Harvard University. Cloth. Price, \$2.50. Pp. 152, with 5 illustrations. New York: Macmillan Company, 1938.

This book is brief but well written and has a few important illustrations. The disturbances of the digestive tract and their diagnosis and treatment are approached principally by an analysis of pain, the chief symptom. The author has concisely presented his experimental observations on pain, produced at various levels of the digestive tract in normal and abnormal states. The clinical application of these experimental observations is then discussed. This discussion is amplified by a series of case reports, which are not only interesting but strikingly illustrative of the principal theme of the author: the importance of pain in the digestive tract. The author has not failed to recognize the importance of gastrointestinal pain in "functional disease." This chapter likewise is well illustrated by case histories. The final chapter is an excellent summary and contains many important therapeutic considerations which show a well ordered conception of the manifold problems of the digestive disorders. The author has indeed presented a concise monograph which should stimulate the gastro-enterologist to continue similar experimental and clinical observations and should likewise be revealing to the general practitioner of the newer concepts of gastrointestinal diseases.

Febrile Episoden bei schizophrenen Psychosen: Eine klinische und pathophysiologische Studie. Von Dr. med. habil. K. F. Scheid, Oberarzt der psychiatrischen Abteilung des städtischen Krankenhauses, München-Schwabing. Boards. Price, 7.80 marks. Pp. 97, with 7 illustrations. Leipzig: Georg Thieme, 1937.

The author presents a study of a small series of psychoses classified as schizophrenic, with conspicuous somatic disturbances, especially fever, cyanosis and tachycardia. Detailed analysis of the changes in the blood picture, blood chemistry and cerebrospinal fluid were made in an attempt to discover the etiologic pathophysiologic process. The cases were selected to exclude all those in which any known exogenous toxic or infectious factors might be present. In the first group of febrile cyanotic psychoses, all acute or subacute, lasting from a few days to a few months, all terminating in coma and death, no adequate explanation of the disease was found at necropsy except dilatation of the heart and venous stasis. In all these cases, as in the cases of febrile and subfebrile episodes during the course of protracted schizophrenic psychoses, the author finds certain changes in the cellular and chemical constituents of the blood indicating a hemolytic process. He concludes from a study of his material that there is a causal relationship between the destruction of blood corpuscles (hemolysis) and these schizophrenic psychoses.

Treatment by Diet. By Clifford J. Barborka, B.S., M.S., M.D., Department of Medicine, Northwestern University Medical School, Chicago. Third edition. Cloth. Price, \$5. Pp. 642, with 8 illustrations. Philadelphia, London & Montreal: J. B. Lippincott Company, 1937.

In this edition some errors have been corrected from the first two editions and articles have been added on the present status of the clinical aspects of the vitamins and the present conception of the use of protamine zinc insulin. This volume fails to take account, however, of the newer discoveries in the field of the vitamins which indicate the chemical nature of these substances. The vast majority of the book consists of tables of food substances, providing diets for all sorts of medical conditions. In the appendix there are additional tabular data related to weights, measures and recipes, and there is also an extensive bibliography. The book serves well as a reference work for the practitioner who simply will not take the time to acquaint himself with the basic information regarding nutrition and diet but who wants to use the results of such considerations.

Speech Training for Cases of Cleft Palate. By M. C. Oldfield, M.Ch., F.R.C.S. Cloth. Price, 4s. 6d. Pp. 18, with 38 illustrations. London: H. K. Lewis & Co., Ltd., 1938.

The title of this book gives promise of more than is actually forthcoming. The material is distinctly disappointing, not because of any intrinsic lack of worth but because of its brevity and sketchy presentation. Of the eighteen pages in the book, two are devoted to an introduction, four to photographs (the most interesting aspect of the book), and the remaining twelve pages to a tabulation of the various speech sounds, with illustrative diagrams and a few simple exercises—all of which may be found in almost any general book on speech. While the author is undoubtedly sincere in her attempt to give the reader the benefit of her own practical experience, which is commendable, a book usually is written to give as complete a presentation of the subject as possible. Actually, the present work is merely a pamphlet elevated to book dignity by having stiff covers. The same material has been presented before and in much greater detail. The book really recommends itself only because of its eight photographs. The speech therapist or interested layman who wishes to gain a more comprehensive knowledge of the subject will undoubtedly have to supplement the volume with other reading.

A Textbook of Hematology. By William Magner, M.D., D.P.H., Pathologist, Saint Michael's Hospital, Toronto, Canada. Cloth. Price, \$4.50. Pp. 395, with 26 illustrations. Philadelphia: P. Blakiston's Son & Co., Inc., 1938.

The author has attempted to describe fully but concisely the clinical features of disorders of the hemopoietic system and the associated changes in the blood and tissues. This objective has necessitated much simplification without attendant inaccuracy, and on the whole the author has met this problem successfully. The controversial features of terminology have been discussed briefly and fairly. The book is not profusely illustrated and for laboratory use it probably would have to be supplemented by a hematologic atlas. Beginning students of the blood and non-specializing clinicians may find this a useful addition to their libraries.

Experimentelle Bakteriologie und Infektionskrankheiten mit besonderer Berücksichtigung der Immunitätslehre. Von W. Kolle und H. Hetsch. Unter Mitarbeit von Prof. Dr. H. Schlossberger. Herausgegeben von Prof. Dr. H. Hetsch. Eighth edition. Paper. Price, 30 marks. Pp. 836, with 92 illustrations. Berlin & Vienna: Urban & Schwarzenberg, 1938.

This is a monumental work. Originally presented by Professors Kolle and Hetsch with the assistance of Professor Schlossberger, it now appears under the editorship of Professor Hetsch, Professor Kolle having died some time ago. The present edition covers nearly every phase of bacteriology, virus diseases and the more important tropical diseases. Each disease is discussed under a separate chapter and the important bacteriologic technical details are given, also the important symptomatology, and a short pathologic discussion of the disease. There are excellent colored plates of smear and culture preparations and numerous black and white reproductions. At the end of each chapter there is a bibliography. Important references to the American literature has been omitted. In the section on virus diseases there is no mention of the work done by Dr. Rivers of the Rockefeller Institute in this country. The important work on streptococci by Dr. Lancefield is not

presented. This book can be highly recommended to the bacteriologist, immunologist and public health worker as well as the student in bacteriology who is interested in a more detailed presentation of the subject.

My Scrapbook of Medicine. By Louis R. Ettler, A.M., M.D., F.A.C.S. With Bibliography and Index. Cloth. Price, \$3. Pp. 248. Toledo, Ohio: McManus-Troup Company, 1937.

This privately published work includes a series of items in prose and in verse collected by the author from various places. Most of the references concern the history of medicine. Some of them are taken from newspaper clippings. The book is printed in mixed deep black and light black type, which makes it difficult to read. In any event, however, it is the kind of book that one picks up for occasional scraps of interesting material rather than as sustained reading matter.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Medical Practice Acts: Conviction Under Harrison Narcotic Act a Felony and Involves Moral Turpitude.—The medical practice act of Texas authorizes any court of competent jurisdiction to revoke a license to practice medicine if the licensee has been found guilty of a felony or of a crime involving moral turpitude. The appellant, a physician, was convicted in the United States district court for the southern district of Texas of violating the Harrison Narcotic Act, he having confessed to the sale of narcotics to an addict. Thereafter the state, on relation of the state board of medical examiners, instituted appropriate proceedings to revoke the appellant's license. The license was revoked and the physician appealed to the court of civil appeals of Texas, Galveston.

The appellant contended that the offense for which he had been convicted was then a felony under the laws of the United States but not under the laws of Texas, and that before his license to practice could be revoked it had to be shown that he had been convicted of an offense which was then a felony under the state laws. But, the court said, the medical practice act does not require, in order to justify the revocation of a license to practice medicine, that the holder be convicted of an offense of the grade of a felony in Texas, but only of an offense that was of the grade of a felony anywhere. Since the conviction of a violation of the Harrison Narcotic Act constitutes a felony, it was plain to the court that the revocation of the appellant's license was justified because of that conviction.

That moral turpitude inhered in the acts from which the conviction resulted was, in the opinion of the court, a legitimate, if not inevitable, inference. The appellant apparently argued that, since the Harrison Narcotic Act was a revenue measure only, a violation of it does not involve moral turpitude. But, said the court, while the Harrison Narcotic Act does have that character so far as may be necessary to uphold the power of Congress under the constitution in enacting it, its further and underlying purpose is to regulate and control the sale of narcotics in consonance with a widespread feeling that it is not good morals to sell such dangerous drugs except in pursuance of the professional ministrations of a physician in treating patients. The record showed not only that the appellant was convicted in the federal court for selling morphine unlawfully but that he was also convicted of smuggling narcotics into the United States. Even though the sale by itself should not be considered a crime involving moral turpitude, the court thought that smuggling is so regarded.

The trial court committed no error in refusing to submit to the jury the question of whether or not the appellant's right to practice medicine in Texas should be canceled. That, obviously, was a question of law for the court.

The appellate court having found no error in the record, the judgment of revocation was affirmed.—*Speer v. State (Texas)*, 109 S. W. (2d) 1150.

Contracts: Agreements in Restraint of Medical Practice Valid If Reasonable.—Two young physicians, the appellants in this case, as a part of a contract of employment entered into with several physicians composing a partnership, agreed that if they, the appellants, terminated the contract they would not within five years from the date of such termination engage in practice in the community or within five miles of its corporate limits. A disagreement arose, the two physicians withdrew from the employment and each entered independently on the practice of medicine in the community. The physicians composing the partnership, the appellees, then instituted proceedings to enjoin the appellants from engaging in practice in contravention of their agreement. The trial court issued the injunction and the enjoined physicians appealed to the Supreme Court of Mississippi, contending that their promise not to practice their profession in the community or within five miles thereof for five years was unenforceable.

It is well settled, said the court, that "a bargain by an assistant, servant, or agent not to compete with his employer, or principal, during the term of the employment or agency, or thereafter, within such territory and during such time as may be reasonably necessary for the protection of the employer or principal, without imposing undue hardship on the employee or agent," is valid "unless effecting, or forming part of a plan to effect, a monopoly." 2 Rest. Contracts, Sec. 516. In the present case, the court pointed out, the limitation of time and space was undoubtedly reasonable, and the evidence disclosed that the public interest would not suffer by an enforcement of the agreement, for the number of physicians in the community was amply sufficient to render necessary medical services to the citizens. No monopoly was either contemplated by the contract or would result from its enforcement.

To enable the physicians forming the partnership to enforce the agreement of the appellants by means of an injunction, it must appear, the court said, that the former performed their obligations under the contract. They would not be entitled to an injunction if they failed to perform their part of the bargain and thereby caused the withdrawal of the appellants from their service. But such did not occur here. The physicians forming the partnership acceded to every demand made on them by the appellants and at no time indicated that they would not perform their obligations under the contract. This being true, there was no default on the part of the partnership physicians which justified the appellants in the course they took.

Finding no error in the judgment of the trial court, the Supreme Court affirmed that judgment enjoining the appellants from engaging in the practice of medicine contrary to the agreement they made.—*Wilson v. Gamble (Miss.)*, 177 So. 363.

COMING MEETINGS

- American Medical Association, San Francisco, June 13-17. Dr. Olin West, 535 North Dearborn St., Chicago, Secretary.
- American Academy of Tuberculosis Physicians, San Francisco, June 17-18. Dr. Arnold Minnig, 638 Metropolitan Bldg., Denver, Secretary.
- American Association of Medical Milk Commissions, San Francisco, June 13-14. Dr. Paul B. Cassidy, 2037 Pine St., Philadelphia, Secretary.
- American Medical Women's Association, San Francisco, June 12-14. Dr. Helen A. Cary, 1634 N.E. Halsey St., Portland, Ore., Secretary.
- American Proctologic Society, San Francisco, June 11-13. Dr. Curtice Rosser, 710 Medical Arts Bldg., Dallas, Texas, Secretary.
- American Radium Society, San Francisco, June 13-14. Dr. F. W. O'Brien, 465 Beacon St., Boston, Secretary.
- American Rheumatism Association, San Francisco, June 13. Dr. Loring T. Swaim, 372 Marlborough St., Boston, Secretary.
- American Urological Association, Quebec, Canada, June 27-30. Dr. Clyde L. Deming, 789 Howard Ave., New Haven, Conn., Secretary.
- Association for the Study of Internal Secretions, San Francisco, June 13-14. Dr. E. Kost Shelton, 921 Westwood Blvd., Los Angeles, Secretary.
- Maine Medical Association, Bar Harbor, June 26-28. Dr. F. R. Carter, 22 Arsenal St., Portland, Secretary.
- Medical Library Association, Boston, June 28-30. Miss Janet Doo, 2 East 103d St., New York, Secretary.
- Minnesota State Medical Association, Duluth, June 29-July 1. Dr. E. A. Meyerding, 11 West Summit Ave., St. Paul, Secretary.
- National Tuberculosis Association, Los Angeles, June 20-23. Dr. Charles J. Hatfield, 7th and Lombard Sts., Philadelphia, Secretary.
- West Virginia State Medical Association, White Sulphur Springs, July 11-13. Mr. Joe W. Savage, Public Library Building, Charleston, Executive Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1927 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

- Congenital Transposition of the Great Arterial Trunks. D. W. Ingham and F. A. Willis, Rochester, Minn.—p. 482.

Causes of Death in Congestive Heart Failure.—Williams and Rainey analyzed the records of 185 patients who gave a convincing history of congestive heart failure and who died and were subjected to postmortem examination at the Vanderbilt University Hospital during 1926 to 1935. In recent years the life of patients who suffer from congestive heart failure has been definitely increased. This increase seems best accounted for by the more effective control of congestive failure, through the intensive use of mercurial and xanthine diuretics. Death from congestive heart failure and from pulmonary embolism and infarction distinctly decreased in frequency during the period 1931 to 1935. During this period pneumonia, both as a primary and as a supplementary cause of death, increased in frequency, particularly in patients with arteriosclerotic disease. Intensive treatment with salyrgan did not increase the incidence of uremia in the nonhypertensive patients. Uremia occurred with increased frequency in the 1931-1935 hypertensive group as compared with the 1926-1930 group. Whether the increased incidence of uremia in the subjects with hypertensive cardiac disease was due entirely to the prolonged life which resulted from improvement in the treatment of cardiac disease, thus allowing progression of renal damage to occur, or whether in some instances the mercurial diuretics actually favored progression of renal disease cannot be stated with certainty.

Acute Arterial Occlusion.—In a series of thirty-six cases of acute embolic occlusion, Rykert and Graham observed that pain was present as the initial complaint in 64 per cent of cases, was of maximal severity at the onset in 53 per cent and was present in the later stages of the condition in 100 per cent of cases. Pain of maximal severity at the onset usually was located at the level of the occlusion and less often in the distal part of the affected limb, and pain present in the later stages of the condition was always located distal to the site of the occlusion. Arteriotomy provides the only means whereby the obstruction may be removed and the continuity of the occluded artery restored. This is possible only in acute arterial occlusions due to emboli. The satisfactory immediate results following early operation in a considerable percentage of cases of acute embolic occlusion made embolectomy the accepted method of treatment in this condition. Too much stress has

been laid on the satisfactory results that may follow early operation and too little attention has been paid to the late results following embolectomy and to the percentage of spontaneous recovery of the circulation following acute arterial occlusion. In the thirty-six cases of complete occlusion, of the common femoral artery in twenty and of the popliteal artery in sixteen, spontaneous recovery of the circulation occurred in approximately 20 per cent of each group. When acute embolic occlusion of the arteries of the upper extremities occurs in patients not suffering from severe failure of the general circulation, spontaneous recovery would appear to be the rule rather than the exception. The primary disease and not the immediate restoration of the peripheral circulation is the important factor in determining the late prognosis in acute arterial occlusion. As the primary disease is of so much importance in both the causation and the prognosis of acute arterial occlusion from thrombosis and embolism, treatment directed toward the early restoration of the circulation by measures other than embolectomy would seem to be indicated. Alternate suction and pressure therapy has the advantage of being applicable to cases of thrombosis as well as of embolism, and in the treatment of the latter is not limited by the duration of the occlusion.

Electrocardiographic Changes in Carbon Monoxide Poisoning.—In their series of twenty-two cases of carbon monoxide asphyxia, Stearns and his associates found that the most common electrocardiographic deviation is an abnormality in the T waves or in the level of the ST segment; there were eighteen such cases. Four patients showed paroxysmal auricular fibrillation and one showed transitory intraventricular block. Two showed ventricular premature contractions and one auricular premature contractions. Low voltage on the initial electrocardiogram, later improving or returning to normal, was present in five. Variations in the P waves occurred in two. All the patients were admitted directly to the emergency ward on their arrival at the hospital. However, before being removed from the scene of their asphyxiation they had been treated with inhalations of 7 per cent carbon dioxide and 93 per cent oxygen for varying lengths of time. The authors feel that the changes, having been transitory, may be ascribed directly to the carbon monoxide asphyxia, except when coronary disease may have been a contributing cause in some cases. They limit their study to the period of recovery from the marked anoxemia after emergency oxygen and carbon dioxide treatment. The results, while indicating that intraventricular block may result from carbon monoxide poisoning, suggest that this is not the usual outcome.

- Primary Carcinoma of Liver in Childhood: Report of Two Cases, with Critical Review of Literature. M. M. Steiner, Brooklyn.—p. 807.

Nutritional Heart Disease in Children.—Waring presents thirteen cases of cardiac disturbances of nutritional origin. The diagnosis of nutritional cardiac disease was made on the basis of the following observations: cardiac enlargement, shown by percussion and by roentgen examination, without accompanying murmur; negative results of urinalyses; absence or sluggishness of reflexes; a history of deficient diet, and a more or less rapid response to rest and sufficient food. Dietetic histories in most cases were vague, but malnutrition was generally evident. Twelve of the thirteen patients were Negro children aged from 14 to 48 months. The cause of cardiac enlargement does not appear in these cases. Whether deficiency of vitamin B₁, deficiency of protein or general dietetic deficiency

is the fundamental cause is still a matter of some disagreement. All the patients improved on adequate diets strengthened with materials rich in vitamin B₁. It appears that the cardiac changes are not entirely due to a lack of vitamin B₁ but to a rather more general deficiency of dietary materials and that a satisfactory response to dietetic treatment may be expected in cases in which the illness is not too far advanced.

Prophylaxis Against Measles.—Karelitz recommends further trial of the globulin fraction of immune adult serum in the prophylaxis of measles for the following reasons: 1. It has been efficacious in doses easily calculated from the known indicated doses of immune adult serum. 2. It is easily prepared from immune adult blood. 3. The amount of the injection is small compared with the amount of immune adult serum injected, and the serum may be prepared so that the dosage is equal to or less than that of measles convalescent serum; thus the procedure of inoculation is simple. 4. The danger of infecting a child with syphilis, tuberculosis or other diseases is eliminated. 5. The reactions are less severe and the results are more uniform than those after injecting equally small doses of commercial solutions of placental globulin. 6. The solutions of adult serum can be transported and can be stored in the ice box without loss of potency for at least one year.

Thermal Death Time of Gonococcus.—Carpenter and his colleagues determined the thermal death time at 41.5 C. (106.7 F.) on 250 strains of *Neisseria gonorrhoeae*. The results show a variation of from six to thirty-four hours in the heat resistance of the cultures studied. Only 0.4 per cent of the strains had thermal death times longer than twenty-four hours. The mean was 16.1 hours, with a standard deviation of 4.8 hours. Approximately 75 per cent of the strains died within one standard deviation to either side of the mean. The data show no correlation between the thermal death time of the strain of gonococcus and either the localization of the infection or the virulence of the invading strain, as expressed by severity of symptoms. A definite thermal death time is a characteristic of each strain of gonococcus, as the thermal death time was unchanged even after the organism was established in a new host; i. e., a consort. A patient may harbor simultaneously more than one strain of the gonococcus. Thus, cultures isolated on the same occasion from two different diseased sites have showed thermal death times which have varied in length from two to nine hours. A similar variance has been noted in the thermal death times of cultures taken from the same source at different times during a period when the patient was receiving no treatment. In some instances a fever treatment one or two hours less in duration than the thermal death time of the isolated organism has resulted in cure. In other cases, however, when the treatment has been four hours shorter than the thermal death time, cure has not been brought about.

Complement Fixation Test for Gonorrhea.—Weiss and Arnold recommend the use of larger amounts of the patient's serum in the complement fixation test for gonorrhea. Larger amounts of the patient's serum (from 1 to 2 cc.) fix larger amounts of complement. By using the same amounts of complement and increasing the amounts of the patient's serum, the stability of the fixation increases. This observation applies in a similar way to the hemolysin (amboceptor). The more serum that is used in the test, the more stable is the reaction with regard to the use of larger amounts of amboceptor. Large amounts of serum contain more antibodies, and, if used in complement fixation tests, they actually fix the complement to a higher degree than smaller amounts of serum. The result is a higher percentage of positive reactions in instances in

which otherwise negative results would be obtained. The statement that complement fixation tests for gonorrhea are not as stable as observed in syphilis appears to be erroneous on the basis of the authors' results. It is generally accepted that fewer antibodies are present in gonorrheal than in syphilitic serums. In these studies, different amounts of a patient's serum were used and it was found that not only the percentage but also the stability of the positive reactions increases with the use of larger quantities of serum. With the use of from 1 to 2 cc. of serum, positive reactions remain strongly positive even after an incubation period of twenty-four hours. The probable cause of this difference in the amount of antibodies is that gonorrhea is a more or less localized infection while syphilis represents a generalized infection. With the use of larger amounts of serums the percentage of anticomplementary reactions must increase and they are more easily detected. If the serums are properly taken, preserved and prepared for the test the number of anticomplementary serums will not be noticeably increased, even when used in larger quantities. Large amounts of natural amboceptor present in increased quantities of the patient's serum do not interfere with the results of the fixation test when a sufficient number of units of artificial hemolysin is used in the hemolytic system. That the test is not applicable in the first three weeks of the infection does not decrease its value. Whenever smears show definitely that gonococci are present, this test is not indicated or necessary. The proper application of this test is found in conditions in which the clinical diagnosis is uncertain and smears do not show gonococci; in treated cases in which the positiveness of the reaction gradually decreases, the ultimate negative reaction probably indicates cure if the reaction remains negative, and in instances in which there is a definite history of a gonorrheal infection and when it is important to determine whether some foci are still present in the body. A positive complement fixation test for gonorrhea indicates the presence of gonococcal foci in the body.

Iodine Tolerance and Thyroid Function.—Watson affirms that the iodine tolerance test (originally abstracted in *THE JOURNAL* July 4, 1936, p. 76) provides evidence of diagnostic importance in cases of doubtful thyroid disease and that a more comprehensive understanding of endocrine disorders may be acquired by studies of the iodine metabolism. Anatomic and functional abnormalities of the thyroid may be considered from the standpoint of probable alterations of the iodine metabolism.

The nature of such disturbances can be studied by observing the rate and completeness of disappearance from the blood stream of iodine after its intravenous injection. The results of ninety-one iodine tolerance tests in eighty cases are recorded. The thyroid apparently is the only organ which abstracts and stores iodine from the blood. This property is accelerated in conditions of thyroid hyperplasia associated with thyrotoxicosis, as exemplified by the abnormal rapidity with which the iodine leaves the blood. Injected iodine disappears less rapidly from the circulation in hypothyroidism. There is no definite correlation between the iodine tolerance and the basal metabolism. The anterior pituitary through its influence on the thyroid may affect the basal metabolism and the iodine tolerance test in an inverse manner.

Sudden Emptying of Distended Bladder.—Creevy reviewed the postmortem records of seventy-one patients with enlarged prostates who died without being operated on, in order to determine whether sudden emptying of a distended bladder was dangerous. Detailed study of this material led to the following conclusions: 1. The rate at which the distended bladder is emptied does not influence the outcome. 2. It is

impossible to distinguish by examination of the urinary tract at necropsy between bladders emptied suddenly and bladders decompressed slowly. 3. Death was due in 80 per cent of the patients who died after catheterization to renal failure secondary to acute and chronic pyelonephritis superimposed on a varying degree of hydronephrosis. 4. In 20 per cent death was due to extrarenal disease, such as pneumonia, endocarditis, pyemia and peritonitis. In this group are found the counterparts of those sudden deaths recorded in the literature as due to reflex syncope or to shock; these patients, however, died of pulmonary embolism and coronary thrombosis. 5. All the phenomena usually attributed to sudden emptying of the distended bladder may be produced by acute pyelonephritis. The author checked these conclusions against clinical as well as necropsy material. He reviewed two series of patients, all with 500 cc. or more of residual urine due to obstruction at the vesical neck. These two series each consisted of approximately 120 patients. The first group, seen in 1918 and 1919, had been treated with the inlying catheter without regard to the rate of the emptying of the bladder, while the second had been subjected to gradual decompression. Of the first group, 4.1 per cent died without other treatment. The survivors were treated by suprapubic prostatectomy with a mortality of 5.2 per cent. In the second group the mortality was 4.16 per cent and from prostatectomy 5.3 per cent. This supports the conclusion that gradual decompression of the chronically distended bladder offers no advantage over simple catheterization.

Urogenital Tuberculosis.—Henline and Bray stress that urogenital tuberculosis is a localized lesion which is only part of the general disease from which the patient is suffering. Tuberculosis is almost invariably present elsewhere in the body, and recognition of the extent and stage of the disease is essential before local treatment is instituted. The frequency with which tuberculous meningitis and miliary and pulmonary tuberculosis develop as terminal stages in patients with urogenital tuberculosis has not been stressed in the literature. These manifestations may occur during or immediately after diagnostic or surgical procedures, or months or even years later. When they occur in the course of diagnostic or surgical urogenital treatment, it is natural to assume a relationship between the manipulation and the fatal tuberculous lesion. There is no more reason for anticipating a dissemination of the infection after surgery for tuberculosis than after surgical procedures in other pyogenic infections. Seven histories are presented of patients who have died from the progression of a generalized tuberculous process after diagnostic or surgical urogenital procedures.

Malaria in Utero.—Garcia cites two cases of malignant tertian malaria infection occurring during pregnancy and terminating fatally before the onset of labor. In the first case, ring forms, old trophozoites and schizonts of *Plasmodium falciparum* were found in the maternal blood immediately before death and infected cells were found in large numbers in histologic sections of the placenta and a few in the umbilical cord. In the second case a large number of infected cells (young and old schizonts of *Plasmodium falciparum*) were found in the heart and bone marrow of the fetus and a few in the cord. These cases present more definite proof of the existence of transplacental infection in the fetus, he says, than has previously been recorded in the literature.

Follicle Stimulating Factor in Extragenital Conditions.

—Woodman examined sixty-six cases in which there were lesions of the secondary sex organs for their urinary excretion of the follicle stimulating factor. The method used to determine the amount of the factor in the urine was that described by Ferguson (1933). Of the twenty-eight cases of varying breast lesions investigated, two gave positive results—acute abscess (it was later found that the patient was pregnant) and tuberculous mastitis. The positive reaction in the case of tuberculous mastitis cannot be explained unless the patient was pregnant at the time and the pregnancy had a short duration and was terminated without the patient being aware of the fact. All the thirty-two cases of benign enlargement of the prostate, both before and after operation, gave negative results, indicating that the hypertrophy of the prostate which develops in later life cannot be correlated with that form of pituitary activity which is associated with an increased excretion of gonadotropic substance and also that the Aschheim-Zondek test has no diagnostic value in this condition. The only case of pituitary adenoma (associated with acromegaly) gave a negative result. Two cases of teratoma testis were both positive. Another positive reaction was in a woman of 25 who complained of a blood-stained discharge following a miscarriage. Two months after the miscarriage a positive Aschheim-Zondek reaction was obtained. As the discharge continued, curettement was done. Only blood clot and fragments of normal-looking endometrium were found. Three weeks later the Aschheim-Zondek test was negative. Eleven months after the curettement, the patient returned to the hospital with a large mass in the uterus which was diagnosed as a chorionic epithelioma, and a positive Aschheim-Zondek reaction was obtained. She was treated with radium, and a week later the test was repeated and was still strongly positive. She died a day after the last test. A large mass was found in the uterus and vagina, with metastatic nodules in the lungs. In the beginning a normal pregnancy was present. The pregnancy was later terminated in an abortion, which explains the curettage observations and the negative test, but some residual chorionic tissue must have been present, since a chorionic epithelioma developed later; but at that stage it was not sufficient to give a positive Aschheim-Zondek reaction.

Intrathecal Sulfanilamide in Meningococcal Meningitis.

—Eldahl treated twelve patients who had severe meningococcal meningitis with sulfanilamide intrathecally. Their ages varied from 3 months to 4 years. Three patients died. Two patients among those who recovered had meningococcal septicemia. Both children were at the time of their admission so run down that the outlook was hopeless. Nevertheless they got well quickly.

The conclusion reached about the sulfanilamide treatment of meningococcal meningitis is that it has but little effect if the remedy is administered exclusively by mouth or intramuscularly. But if it is given intrathecally along with the other administrations, the treatment is of real value. This is probably because the elimination of the sulfanilamide through the meninges may be both slow and slight when they are inflamed. It is not likely that intrathecal injections alone are sufficient, because meningococci can be found outside the spinal canal, and on these the sulfanilamide, when given by mouth or intramuscularly, can have considerable effect. The amount of the 0.8 per cent sulfanilamide solution injected varies from 5 to 30 cc., according to the amount of spinal fluid withdrawn but is always less than the amount withdrawn. The intramuscular doses have been from 35 to 150 cc., according to the weight of the patients. The average fatality rate of meningococcal meningitis in the author's hospital for the last six years has been 70 per cent for children less than 4 years of age.

Serologic Studies in Epidemic Influenza.—The reason for the relatively short duration of immunity to influenza has not been determined. In view of the high antibody content, usually found in those who have recently recovered from infection, this low-grade immunity is surprising. The probable factors are the existence of several immunologically distinct strains of virus and the rapid disappearance of the antibodies produced by infection. As a number of recently infected persons were available, Fairbrother and Martin studied the fluctuations in the antibody content of their serum over periods of from ten to twelve months; i. e., the part played by the second of the foregoing factors. The antibody titer appears to be a simple index of resistance to infection—absence of antibodies or a relatively low titer indicates susceptibility and a high titer resistance. The critical level that demarcates these two states cannot however be defined with any accuracy. The high level in the antibody content of the serum is not maintained and after from ten to twelve months the titers tend to fall to a level similar to that given before infection.

Vitamin K in Human Pathology.—According to Dam and Glavind, thrombopenia, aplastic anemia, hemophilia, nontropical sprue, myeloma, acute hepatitis, obstructive jaundice, cholelithiasis and cancer may be expected to influence the clotting time. A reduced platelet count has no influence on the clotting time. That injection of a vitamin K concentrate may restore the clotting power of the blood of K avitaminous chicks is known. Therefore the authors gave intramuscular injections of K vitamin concentrates to three patients (one of cancer and two of obstructive jaundice due to cancer) with increased clotting values. The parenteral introduction of 15 mg. of vitamin K daily rendered the clotting power normal in from six to eight days and therefore it is concluded that the increased clotting time before the introduction was due to reduced absorption of vitamin K from the intestine. Experiments on rats having bile fistulas were carried out by Greaves and Schmidt in 1937, who found that an excess of vitamin K in the food counteracted the hemorrhagic diathesis. Warner, Brinkhous and Smith report that the action of alfalfa extract mixed with bile and given by mouth was superior to the usual bile therapy.

Electro-Encephalogram.—Marinesco and his associates point out that it was Berger who first attempted to visualize the variations in the electric potential derived from the cranium. As electrodes he employed needles, which he attached to the scalp after local anesthesia and he made the registration by means of an oscillograph. On the graphic record obtained in this manner he differentiates waves of a frequency of from 8 to 10 Hertz and of a maximum potential of 0.2 millivolt, designated by him as alpha waves; and waves of a greater frequency but a smaller amplitude, which are superimposed on the first and are designated as beta waves. The alpha waves are dependent neither on the respiration nor on the pulsation and consequently they must be an electrical rhythm of the cerebral cortex. Berger's observations were confirmed, completed and extended by a number of other investigators. Marinesco and his associates studied this problem for the last two years. They made their electro-encephalograms either with the method of Berger, by attaching the needles to the anesthetized scalp, or by applying the impolarizable electrodes to the shaved scalp. In the construction of the impolarizable electrodes the authors followed the method used by Lapicque for the electrical excitation of the nerves. Like other investigators, the authors encountered difficulties in interpreting the results. As the most constant characteristic of an electro-encephalogram they regard the frequency of the alpha waves; in the same subject these waves maintain the same level during the entire duration of the recording. The authors regard as anomalies considerable diminutions and augmentations of the frequency, which occur transiently in the course of the recording. On the other hand, the amplitude of the waves varies considerably in the course of a recording. In certain pathologic conditions, several modifications may become manifest. In this paper the authors report their observations on the electro-encephalograms of patients with such disorders as tetany, epilepsy, aphasia, cerebral tumor and coma. They found that in some pathologic cases the anomalies of the electro-encephalogram consisted especially in modifications of the amplitude (epilepsy, tetany) or of the amplitude and of the frequency (aphasia, cerebral tumors and so on). The pathologic cases, with modifications of the frequency but without changes in the amplitude, are extremely rare. Generally a diminution in the frequency is accompanied by a diminution of the amplitude, as for instance in aphasia and in certain cerebral tumors and even with an augmentation of amplitude, as in a case of coma. Nevertheless there are exceptions. In some of the reported cases of aphasia the frequency alone was diminished. But this reduction in frequency was accompanied, if not by a modification of the amplitude, by the intercalation of long pauses. In two cases of cerebral tumor the authors encountered an augmentation of the frequency (15 Hertz in the one, to 18 Hertz in the other) without modification of the amplitude. Likewise, in dementia paralytica the authors occasionally encountered a diminution of the frequency without modification of the amplitude. But this occurrence is rare; in the ninety pathologic cases examined, the authors observed it only eight times.

Mobilization of Lead in Saturnism.—Teisinger shows that the determination of the lead content of the blood is the best diagnostic method in chronic lead poisoning. It is better than the determination of the lead in the urine and in the stool. The most convenient method is the micropolarographic one, because it requires only a small quantity of material and it is at the same time rapid and exact. In advanced cases of

lead intoxication, with all or some of the objective symptoms, the lead content of the blood is always increased. If the intoxication is recent, the high lead content of the blood confirms the diagnosis of intoxication even if the objective symptoms are missing. In extremely chronic cases the lead content of the blood may be normal, even in case of positive intoxication. In these cases diagnostic mobilization may be considered a primary sign. The best means to effect this mobilization are potassium iodide or sodium bicarbonate. The author employed mobilization by means of potassium iodide in eleven cases. The patients were given 10 Gm. of potassium iodide in the course of a week. In five of the cases the result was positive and in the six others the result was negative. Since none of these patients had presented the objective signs of saturnism, it would have been difficult to diagnose the lead poisoning otherwise. Sodium bicarbonate, which increases the elimination of lead in the urine and feces, was used by the author in eight cases. The patients were given 50 Gm. of sodium bicarbonate in the course of a week. In four of them the result was positive; in the other four it was negative. In three of the positive cases, objective symptoms of saturnism existed. Discussing the mobilization by means of parathyroid extract, the author says that this method was first employed by Hunter and Aub. In view of the fact that the metabolism of lead is closely allied with that of calcium, it is assumed that parathyroid extract will influence it. The author decided to try mobilization by parathyroid extract in one case in which saturnism seemed possible and in two cases in which it was certain. In none of the cases did the administration of parathyroid extract result in an elimination of lead or an elevation of the lead content of the blood. However, animal experiments on the mobilization of lead by parathyroid extract proved successful. The author thinks that great differences exist in the potency of parathyroid extract and emphasizes that only those preparations should be used the potency of which is controlled.

Uranin Elimination as Functional Test of Stomach.—

Rotter cites several functional tests of the stomach but directs attention especially to the dyestuff method of Goldstein and Erber, because it was to be expected that this method would be an aid in the differential diagnosis of ulcer and gastritis. Goldstein and Erber studied the resorption of the dyestuff uranin through the gastric mucosa and discovered that the resorption is more rapid in patients with ventricular and duodenal ulcer than in patients with normal stomachs or with gastritis. Rotter decided to investigate the reliability of the method as a differentiating factor between gastritis and ulcer. On the whole he followed the technic used by Goldstein and Erber. The patients, who had emptied the bladder at 5 a. m., drank at 8 or 9 a. m. 1 Gm. of uranin dissolved in 250 cc. of slightly sweetened tea. Beginning with the fifth minute after this the urine was evacuated at one minute intervals and the first appearance of a noticeable fluorescence was watched for. In order to avoid errors due to the color of the urine and to the difference in quantity of urine contained in the bladder, Rotter catheterized the patients before the test and introduced into the bladder 250 cc. of a sterile, tepid physiologic solution of sodium chloride. In comparing his results with those of Goldstein and Erber he says that, whereas Goldstein and Erber observed an accelerated elimination of uranin in patients with gastric or duodenal ulcer, he observed a retardation. He found that the time after which the physiologic solution of sodium chloride that is introduced into the bladder shows noticeable fluorescence is influenced by many factors that may cause a disturbance. He thinks that the most important of these factors are the anatomic impairment of the gastric mucosa by a chronic inflammation and the readily influenced secretory function of the kidney, whereas the acidity values of the mediums that dissolve the uranin apparently exert no essential influence on the outcome of the test. Moreover, the fact that the mucosa

of the small intestine absorbs the dyestuff in the same measure as does the gastric mucosa shows that the method is not really a test of the gastric function. The author concludes that the uranin test cannot be recommended as an auxiliary functional test of the stomach.

Extrarenal Azotemia in Diseases of Nervous System. D. De Paolis.—p. 182.

*Meningeal Reactions from Serum. F. Rocchi.—p. 187.

Meningeal Reactions from Serum Therapy.—Rocchi discusses the significance of the meningeal reactions which follow intraspinal injections of heterologous serum and the danger of the reactions which take place in the course of serotherapy in epidemic cerebrospinal meningitis. He followed the behavior of the meningeal reactions which took place in the course of intraspinal injections of heterologous serum in patients who were suffering from poliomyelitis, tetanus and meningococcic meningitis. The meningeal reaction takes place whether or not the meninges are inflamed. The reaction develops within twenty-four hours of the injection, reaches its greatest intensity in two days and diminishes or disappears in a week. Even though further intraspinal injections of serum are administered, the reaction disappears. The meningeal reaction may include the appearance of clinical meningeal symptoms in association with changes of the cytology of the cerebrospinal fluid or only the latter. The cytologic reaction consists in a predominant polynucleosis in the cerebrospinal fluid with a few histiocytes. The clinical symptoms and the colloidal reactions of the cerebrospinal fluid are of a meningitic type. Glycorrhachia is normal. General symptoms of serum anaphylaxis may develop in the course of the reaction, but in all his experience the author has never seen meningeal anaphylaxis. He classifies the meningeal reactions from intraspinal serum therapy as immediate (clinical and cytologic) and late (general or focal anaphylactic) reactions. He suggests the name "meningosis" for the meningeal serum reactions. The nature of this reaction, either toxic or anaphylactic or showing an aggravation of meningococcic or suppurative meningitis, can be ascertained by the cytology of the cerebrospinal fluid. The polymorphonuclear leukocytes, which are in abundance in the cerebrospinal fluid during the meningeal reaction, are well preserved and take a stain normally when there is no meningitis. Pus shows in the cerebrospinal fluid by the Cesaris-Demel reaction when there is meningitis. The author concludes that toxic or anaphylactic reactions from serum do not develop as frequently as believed and that the fear for the development of the reaction is not an obstacle in administering a prolonged serum treatment in epidemic cerebrospinal meningitis.

*Action of Antivirus in Experimental Pleurisy. P. Stefanini.—p. 173.
Familial Osteogenic Exostoses, Associated in a Case with Bilateral Dyschondroplasia and Solitary Enchondroma of Pelvis. M. Teramo.—p. 185.

Antivirus in Experimental Pleurisy.—Stefanini says that antiviruses are nontoxic substances which inhibit the development of specific bacteria "in vitro" and cause local immunity when they come in contact with organs and tissues of living bodies. The author studied the action of a staphylococcus antivirus on experimental staphylococcic pleurisy in rabbits. He found that the intrapleural injection of a dose which may vary from 1.5 to 3 cc. of a twenty-four hour bouillon culture of *Staphylococcus aureus* induces an acute purulent pleurisy with death of the animals in three days. Intrapleural injection of doses varying from 4 to 6 cc. of the antivirus, twenty-four hours before injection of from 2 to 3 cc. of the bouillon culture of staphylococcus, prevents development of pleurisy. The animals survive the experiment and when they are killed do not show pleuropulmonary lesions. If the antivirus is intrapleurally injected at the same time as bouillon culture, pleurisy may be prevented, provided the quantity of antivirus is larger than that of the culture (one part of bouillon culture to six parts of antivirus). If antivirus is injected in the course of pleurisy, the

evolution and acuteness of the disease are not modified. The duration of life of the animals in this group is not prolonged in comparison to that of the control animals. The author concludes that staphylococcus antivirus causes local immunity in the pleura. The antivirus has an immunizing effect on the pleura and not a therapeutic effect on pleurisy. Therefore it has no clinical application in pleurisy. However, it can be of use in preventing metapneumonic and parapneumonic empyema in the course of pneumonia or bronchopneumonia. He advises the preparation of "stock" antivirus from bacteria that most frequently cause pneumonia and bronchopneumonia. The use of a given antivirus will be decided from the report of the bacteriologic examination of the sputum in each case. Intrapleural injections of "stock" antivirus will also be indicated immediately after lobectomy and pneumonectomy to prevent postoperative pleural infections. Doses of antivirus for the last mentioned purposes are not as yet determined.

Lipophage Disease of Knee Joint.—Biebl says that, although the lipophagic granuloma in its nonarticular localizations has been thoroughly investigated, the lipophagic disease of the knee joint is unknown in the medical literature. He describes two cases of lipophage disease of the knee joint. In both the disorder was posttraumatic and gave the impression of a relapsing effusion into the joint. The author surveys the literature on the clinical aspects, pathology, etiology, morphology, morphogenesis and localization of the lipophagic disease process, including the paraffinoma, oleogranuloma and transplantation of fat tissues. In lipophagic disease of the knee joint, which includes lipophagic synovitis and lipophagic articular granuloma, the author was able to demonstrate that the small cyst or cavity formations which are typical for lipophagic granuloma are at least partly of lymphogenic origin. The author suggests that lipophagic disease of the joints is probably always posttraumatic and derived from a lipohemarthrosis. It may involve any joint but is found chiefly in the knee joint. The author thinks that active puncture treatment of hemarthrosis is important for the prevention of lipophagic disease of the joints. The clinical manifestation of lipophagic disease of the knee joint is chiefly a chronic relapsing effusion after a trauma. In every posttraumatic relapsing effusion into the knee joint, the development of a secondary lipophagic disease should be thought of. The disorder may heal spontaneously and with the aid of symptomatic treatment. If under the influence of conservative treatment there is no improvement, danger of a chronic impairment of the

knee exists. In some of the disorders of the knee joint which are referred to as chronic villous synovitis or as hemorrhagic synovitis and which often date back to a trauma of the knee, an essentially lipophagic genesis is to be suspected. Moreover, one or more described or multiple intra-articular xanthomas or xantho-granulomas or xanthomatous giant cell tumors or sarcomas of the knee and ankle joints, which likewise can frequently be traced back to a trauma of the knee, may originally have been of lipophagic genesis. In case of chronic relapse of an effusion of the knee joint, which two or three months after the trauma has disappeared neither spontaneously nor in response to conservative treatment, surgical intervention is indicated. Operative treatment of lipophagic articular disease may produce a complete cure. During the early stages of the disease the intervention should be limited to the partial excision of the intra-articular disease foci. The hyperemia induced by the surgical intervention favors the complete cure. The cases of lipophagic disease of the knee joint which have become chronic require radical synovectomy.

Venous Stasis as Surgical Treatment of Pulmonary Tuberculosis.—After citing the shortcomings of Bier's and Kerschner's methods of the artificial production of stasis hyperemia in the treatment of pulmonary tuberculosis, Valkányi describes his own extrapleural, transpericardial, that is, extra-focal, selective procedure, which is really not a pulmonary operation but rather a cardiac intervention, aiming at cure of the lung. In this connection the author points out that thoracoplasty, for instance, is likewise not a pulmonary operation but rather an intervention on the thoracic wall. He gives a detailed description of the technic of his lobovenoligature with illustrative diagrams. Describing the intervention on the left side, he says that he makes a transverse, slightly curved incision in the second intercostal space, which reaches from the left sternal rim to the anterior axillary line. The sternal attachment of the thoracic musculature is pushed aside, and after the second and third costal cartilages come into view they are resected together with from 5 to 7 cm. of the respective ribs. The mammary artery and veins are ligated twice and sections (from 1 to 2 cm.) are resected. The posterior articular ligament of the two sternochondral joints is cut into and the sternal attachment of the intercostal musculature is severed and pushed aside. The endothoracic fascia and the transverse thoracic muscles are lifted from the pleura and incised. After the pleura has been mobilized it is pushed aside and a narrow strip of the mediastinal fat tissues and the pleura of the other side come into view. Farther downward, the mediastinal fat tissue becomes wider and passes into the pulsating pericardium. The latter is opened at the lower angle of the incision, at the level of the fourth costal cartilage, behind the sternum. The opening is lengthened to the level of the second costal cartilage. At the level of the upper rim of the third costal cartilage an incision is made which is vertical to the pericardial incision. An anesthetizing fluid is injected into the exposed phrenic nerve. The left lip of the pericardial opening is drawn to the left and the heart is pushed carefully to the right. In the upper angle of the opening, the bulb of the pulmonary artery as well as its left branch become visible, and deeper down and in the caudal direction the left upper pulmonary vein is reached, which is ligated. After mentioning the closing sutures, the author describes the procedure on the right side, which is slightly more difficult. He emphasizes that the rather difficult surgical technic necessitates considerable practice on cadavers. He performed this operation on five patients, one of whom died. In another patient, the operation produced no improvement in the pulmonary process. In this case the process had existed for a long time and the pulmonary lobe had a number of cicatrized cavities. The author thinks that in such cases the venous ligature is not advisable. In one case, with a cavity in the upper lobe, ligation of the vein produced cure in from four to five months. In two other cases he obtained improvement, and in one of these complete cure may be expected. The heart was watched carefully after the operations, but in none of the four surviving patients was a permanent impairment observed. Electrocardiographic tests made two weeks after the operation and repeated several times always dis-

closed normal heart action. The mode of action of the lobovenoligature is not completely understood as yet. At any rate its action differs from that of collapse therapy, particularly thoracoplasty. The venous stasis does not cause shrinkage or a compression of the cavernous walls, but a network of strands develops and the cavity becomes filled out.

Fatalities During Labor.—The statistics presented by Leidenius include all fatalities that occurred in pregnant, parturient and puerperal women during the two decades from 1914 to 1933 at the obstetric clinic of the University of Helsingfors. The total number of deliveries was 47,793. In order to determine whether the mortality rate underwent changes, the material is divided into two groups, the first one comprising the material of the first decade (1914 to 1923), the second one that of the second decade. During the first ten year period the number of deliveries was 22,196. The total mortality during this period was 0.45 per cent. Among the fatal cases there were a considerable number in which not the process of gestation but conditions such as tuberculosis or pneumonia were the cause of death. The latter mortality is referred to as "indirect." During the first decade the indirect obstetric mortality amounted to 0.11 per cent, the direct one to 0.34 per cent. During the second decade the number of deliveries was 25,597 and the total mortality was 0.38 per cent, of which 0.05 per cent was indirect and 0.33 per cent direct. The most important causes of death in the two groups were respectively infection 61.8 and 45.9 per cent, toxemia 23.7 and 27.1 per cent, hemorrhage 9 and 8 per cent, cardiac defects 5 and 12 per cent and embolism two and four cases. About 50 per cent of the patients who died were already infected or even moribund at the time of hospitalization. If these cases are excluded the total mortality is 0.18 and 0.17 per cent, respectively. In the concluding discussion the author directs attention to the importance of heart disease as a causal factor in obstetric mortality. He also stresses the necessity of supervision and financial aid during the period of pregnancy and he recommends the foundation of maternity hospitals that are within reach of every pregnant woman.

Premature Rupture of Amnion.—Wetterdal bases his discussion on 1,022 cases in which the liquor amnii was discharged before the beginning of labor. He distinguishes two categories: cases in which the delivery is quick and which present only few complications and cases in which the delivery is slow and the complications are numerous. Particularly risky are the cases in which faint ineffective pains set in shortly after the passage of the waters. The author is of the opinion that the ineffective pains and not the premature rupture of the membranes is the primary factor in such cases. An examination of 150 cases in which the waters escaped before the onset of the pains shows that in some of these cases uterine contractions occurred even before the perceptible pains began but that in the majority of cases no labor pains can be traced to the time of the passage of the liquor amnii. Consequently the suggestion that the rapid deliveries in cases of premature rupture of the bag of waters are due to the fact that a smaller or larger portion of the process of labor has already taken place before the rupture of the membranes cannot be applied to all cases. In 312 cases in which the waters escaped before the onset of the pains, studies were made on the primary and late mortality as well as on the physical and mental development of the children up to the age of 12. These 312 cases comprise 221 spontaneous deliveries and ninety-one forceps deliveries. A comparison with figures from an earlier report show that the premature escape of the waters influences neither the mortality nor the percentage of mental or physical defectiveness in the children.

THE AIMS OF THE MEDICAL PROFESSION AS THEY RELATE TO THE PUBLIC

PRESIDENT'S ADDRESS

IRVIN ABELL, M.D.

LOUISVILLE, KY.

The doctor has long been considered an individualist; in some quarters he is still so regarded. This should be accepted as a compliment as far as the diagnosis, treatment and confidential relationships of private practice are concerned. The physician's absorption in and devotion to the development of the ever widening field of medicine, his concentrated interest in the solution of the problems presented by individual patients, his sense of personal responsibility in the welfare of each patient quite naturally tended to the growth of habits of mind and thought that characterized him as an individualist. Such a mental attitude has been and still is necessary in the practice of curative medicine, constituting an essential attribute in its successful application. The result of the application of a constantly growing medical knowledge has become as apparent to the patient as to the community, of which he is but a part. With this has come to the doctor a realization that as an integral and important part of the community his interests are far wider than those embraced in treating the individual. While this is still one of his major functions, the conception that it is his sole duty is narrow. To this function have been added others which to the public are of greater importance; namely, the maintenance of health and the prevention of disease. Now that social and economic changes have disrupted what were formerly regarded as established policies in both the social and the professional aspects of organized society, the physician finds other problems and duties to which professional responsibility demands that he give attention.

MEDICINE AS A PROFESSION

Medicine is a profession, the sole social reason for its existence being the service it can render humanity; financial gain is a subsidiary consideration. The American Medical Association was formed in 1847 with the avowed purpose of furthering the art and science of medicine and of rendering service to humanity. That service is further interpreted as the maintenance of health and the postponement of death. It is not a trade union and does not concern itself specifically with the rate of compensation, the hours and place of work: it

builds no trusts, founds no monopolies, excludes no qualified competitor and retains for its profit no worthwhile discovery; it engages in no political activity, calls no strikes and answers alike calls from the storm and windswept country, the streets of the village, the boulevards of the city and the desolate field of battle. It does observe the qualification of those desiring to engage in the practice of medicine, their integrity and probity. It demands that the medical service dispensed by every physician meet the standard which it has set; namely, that it be good medical care.

THE RISE OF PREVENTIVE MEDICINE

In view of the present agitation by would-be reformers, it is well to bear in mind that all the improvements in medical service during the past fifty years have been initiated in and put into operation by the medical profession without compulsion, political, governmental or otherwise. A consideration of your time and patience forbids detailed enumeration, but certain definite results may be mentioned. Plagues no longer decimate our population; the toll of the infectious and communicable diseases has been stayed; typhoid is all but a thing of the past; infant and child mortality have been curtailed and tuberculosis, formerly known as the Captain of the Men of Death, has been made to give ground until the mortality from it now is but one fourth that at the beginning of the century. There has been a reduction of 50 per cent in the total mortality and an increase of nearly 100 per cent in longevity—a truly remarkable social phenomenon.

MEDICAL EDUCATION

Medical schools, as a result of more stringent requirements, have been decreased in number, the courses of instruction augmented and prolonged, so that the graduate of today is a competent mentor for the sick. This contribution on the part of the American Medical Association to the elevation of the standard of American medicine has been made at the expenditure of much time, effort and money. The results of this outlay of its capital have fully justified the wisdom and altruism of such a course. The medical schools of this country today are equaled by but few and surpassed by none of other countries. Notwithstanding the increased educational standard, the number of graduates today remains the same as under the old régime in operation at the beginning of the century, while the output is of a superior quality, affording assurance of the maintenance of a higher standard of medical practice. The most valuable asset possessed by the medical profession is the constantly accumulating fund of knowledge in the minds and the literature of its members. Since "a profession has for its prime object the service it can render humanity," all its knowledge must

President's address before the American Medical Association at the Eighty-Ninth Annual Session, San Francisco, June 14, 1938.

be available for the attainment of that object. In directing the education of those who would enter its portals, the medical profession is but fulfilling its responsibility to the public not only in making its fund of knowledge available to the student but in requiring of him evidence that he has acquired it in sufficient amount to make him a safe exponent of its dispensation. Hospitals of fifty years ago were but boarding houses providing creature comforts for the sick; today they are institutions affording not only ample accommodation but, as well, trained personnel, technical equipment, adequate nursing, competent staffs and means for carrying out scientific procedures. These attributes insure an efficient service meeting the requirements which modern medical knowledge and humanitarianism demand as the unequivocal right of the sick at the hands of those to whom they entrust their welfare. Medicine with its component special fields has advanced until it has become more and more a science, its accumulated knowledge being dispensed through and with the art of its votaries. Approximately twelve million patients are treated yearly in the hospitals of this country with a mortality, in the approved hospitals, of slightly less than 4 per cent. When one considers that this covers all known causes of death, there is reason for gratitude that modern medicine has surrounded hospitalization with such effective safeguards. These improvements in medical education and in hospital service have entailed the expenditure of more than a million dollars by organized medicine and represent a contribution in service of no little import to the welfare of our fellow citizens.

THE PROBLEMS OF PSYCHIATRY

Psychiatry throughout the past century has been a veritable *terra incognita*: only when the injunction *sit lux* of modern science was applied to it has it emerged from the gloom and darkness with which it was enshrouded. Asylums were but domiciliary institutions for the confinement of the mentally ill. From these archaic structures modern hospitals are arising, staffed by competent personnel, registered nurses and aiders versed and trained in psychiatry, meeting the challenge of the disordered mind with an orderly mind skilled in the application of scientific, psychiatric knowledge. In some measure dementia paralytica is responding to fever therapy, dementia praecox to insulin and metrazol shocks, involutional melancholias to endocrine therapy. Functional psychoses are being corrected. As a result the percentage of restorations to community life shows a yearly increase.

THE GENERAL PRACTITIONER AND PREVENTIVE MEDICINE

While the major responsibility for preventive medicine devolves on the United States Public Health Service and the state and local health officers, the physician in practice has come to a realization that his obligation to society demands an extension of activity beyond the intimate personal relationship between the individual patient and himself to the broader field of preventive medicine. He is widening his sphere of responsibility from the care of patients to that of the community of which the patients are a part. Sanitation, immunization, maternal and child welfare, antepartum care, public health nursing, mental and social hygiene are a part of this program. An interested public participates through many worth while organizations, of which the Society for the Prevention and Control of Cancer,

the National Tuberculosis Association, the League for the Prevention of Blindness, mental hygiene and parent-teachers associations and others are doing excellent work. Legal enactments permitting sterilization of the unfit and requiring a clean bill of health on the part of those who would enter the marriage state, while more specifically in the field of eugenics, give further evidence of the interest of the public in this general program. Today a large bulk of scientific medical measures of vast value in both preventive and curative medicine must wait until the level of the intelligence of the people is prepared to accept them. Schaudinn in 1905 discovered *Spirochaeta pallida*, Wassermann in 1906 introduced the serum diagnosis of syphilis, and Ehrlich and Hata in 1910 discovered arsphenamine: yet only in 1937 was the word syphilis permitted in the public press and on the radio. For years every physician has sensed the ravages of the social diseases and the beneficent results that would follow their eradication or control, but it remained for Surgeon General Parran to force this recognition on a prudish, recalcitrant public. It has been truly said that preventive medicine forms the keystone of the triumphal arch of modern civilization, since the prevention of disease, and therefore the prevention of suffering and death, is a more important and glorious achievement than the cure of the individual or the reduction of mortality from a given disease. A noteworthy accomplishment, largely attributable to prevention, has been the increase in life expectancy, which now stands at 61 years, indicating that we are slowly developing a society in which old age with its degenerative conditions will represent a constantly increasing percentage of disease.

GRADUATE EDUCATION AND THE SPECIALIST

The growth and development in the art and science of medicine during the present century have been unprecedented: its accumulation has been so rapid and so extensive as to upset all previous conceptions both as to its acquisition and as to its distribution. Not only is the recent graduate perplexed in preparing himself for a special career in medicine, but the graduate of some years who has not kept abreast of the current finds himself woefully lacking in the newer knowledge and procedures, with a consequent failure in understanding of their principles, application and usefulness. Realizing the elimination of this deficiency to be one of its obligations to the public as well as to the profession, organized medicine is providing ways and means of graduate education for those who desire to become specialists and opportunities for the further training of those who are not specialists. In the past the term specialist has been loosely applied. While many had taken the training to fit them for such an appellation, there were those whose only claim to such distinction was a vocal one. In the future the stamp of approval of the various specialty boards will clearly indicate both to the profession and to the public those who have taken the requisite training and who have given a satisfactory demonstration of their fitness before obtaining certification as specialists.

HOW ORGANIZED MEDICINE PROTECTS THE PUBLIC

The American Medical Association maintains a number of bureaus whose activities are directly concerned with public welfare. The Bureau of Health and Public Instruction is specifically concerned in the dissemination of health information to the public by

means of correspondence, by cooperative relationships with organizations interested in public health, by radio through network programs and by service to the public in answering by mail the many thousands of questions coming to it annually. Methods have been devised for the protection of the public health and put in operation through the Council on Pharmacy and Chemistry, the Council on Foods, the Bureau of Investigation, the Council on Physical Therapy, and to a lesser extent in other departments in determining and enforcing standards of value and of advertising used in the sale to the public or to physicians of various articles and services purporting to be of value in the maintenance of health and in the treatment of disease. The rules adopted by the Council on Pharmacy and Chemistry illustrate the application of a system of ethics based on the supreme good of protecting public health. They bar all secrecy as to ingredients and demand that claims be supported by scientific tests, that all advertising must be truthful and that drugs the administration of which should be accompanied by medical diagnosis and supervision be not sold directly to the public. These are simple, straightforward rules the social desirability of which in the whole field of advertising few would dare openly to deny. It is equally axiomatic that they could be made legal only against the strongest possible opposition from those who profit by deceiving the consumer.

DISTRIBUTION OF MEDICAL SERVICE

In the economic upheaval and resultant change in the social and economic structure of our country in the past few years, much has come about that is at wide variance with what heretofore has been regarded as fixed and established policies. There has been a tendency to impress commercial and financial patterns on all features of society, including medicine. A corollary of the tendency to emphasize mechanical devices is the attempt to standardize medical procedures and to provide them on a low cost, mass production scale. Such attempts are based on the belief that a human being can be regarded as a uniform, standardized organism. This is a fundamental fallacy; no two people react in the same way to the same disorder. There is no way to standardize the infinite variety of human beings in health and disease. There has been abuse and criticism of the medical profession with an insistent demand that it propose a plan for a wider distribution of medical service. The difficulties of supplying needed medical care differ almost as widely as do the states constituting this vast nation. Our population is not homogeneous: the labor element recruited from various European countries congregated in the cities of the North and East differ materially from the Negro of the South and from the labor population of our Southwestern states. The geographic distribution of population and of hospital and medical facilities varies from the densely inhabited Northeast to the sparsely settled South and West. The economic level in the various counties and states of the nation alternates from pauperism to opulence. To formulate a program to meet the actual needs of the indigent and partially indigent is no simple task. The trial and error experience with social and economic programs on the part of the federal government in recent years affords ample proof of the difficulties and disappointments encountered. When we face the fact that social and economic factors are inextricably bound with the distribution of medical service to the indigent and partially indigent, the intricacies of the problem become apparent. Organ-

ized medicine from prolonged and intimate observation is fully cognizant of the social and economic needs that lie so heavily on the indigent and the low income groups; while willing and solicitous to do its share in their care and rehabilitation by supplying good medical service to those who require it, the profession of medicine does not feel it a responsibility to initiate or sponsor measures looking toward social and economic reformation. At the same time it resists efforts and proposals that would include and regiment its services under lay or political control for the accomplishment of these ends. There is no definite means of computing in monetary valuation the service voluntarily rendered these groups during the past eight years, but from such data as are available a fair estimate based on a minimum fee schedule would place it in the neighborhood of a million dollars a day, a contribution not equaled or exceeded by any agency other than the federal government. Surely this offering for the public good would indicate that medicine has more than fulfilled the obligation implied in its Principles of Medical Ethics to give of its services to the needy and that as a profession our ideal and our aim have been the provision of service rather than solicitation for compensation. During this period more than 250 plans for the distribution of medical service to the low income groups have been tried in various parts of the country, and as a result much useful data and information have been accumulated. Organized medicine insists on a high standard of value in medical service. Any plan or proposal for wider distribution must be judged on its consonance with good public policy and the maintenance of such a standard.

DEFECTS OF STATE MEDICINE

A study of state-controlled medicine in other countries judged by these standards shows the following defects:

1. There is no decrease in the cost of medical care: the system adds a staggering administrative cost.
2. Public health and preventive medicine are not assisted or advanced.
3. Overmedication is encouraged.
4. The burden of cost is distributed over the low income class, which is least able to bear it.
5. Medical care for the indigent is omitted.
6. Graduate education is not encouraged.
7. The hospital load is increased and hospitals are encouraged to practice medicine.
8. Diagnosis and treatment are mechanical and superficial.
9. Medical service becomes a political issue and its control is placed in the hands of unqualified nonmedical workers and organizations.

These are only a few of the characteristics of the systems of state-controlled medicine. Even at its best do the American people and the American physicians want such a system?

CRITERIA OF GOOD MEDICAL SERVICE

The medical profession has not discharged its entire obligation to society by healing the sick and preventing disease. Its broader obligation lies in a concerted determination and effort to preserve that form of medical practice which best conforms to good public policy and which will perpetuate the free, independent, scientific and ethical institution of medicine. It must vigorously resist all efforts that are likely to provide sick people with the mere dregs of a medical service or that are destined to reduce medicine to serfdom. Any proposed change is to be evaluated by certain criteria.

Would it provide better doctors than are now available?

Would it make good medical care more available to the indigent, the unemployed and the low income groups?

Would it enable physicians to devote more time to the care of the individual patients, especially to the seriously ill patients?

Would it provide more time and more inducement to physicians to keep up to date in their professional work by postgraduate study and clinical work?

Would it eventually reduce the average duration of illness in the United States?

Would it maintain or improve the present standards of preventive medicine?

Would it continue to attract the highest type of men and women into medicine as a life work?

Would it reduce or increase the national cost of medical service?

The American Medical Association with the cooperation of county medical societies, state and local health agencies, hospital authorities, the dental, nursing and correlated professions, welfare agencies and community chests has been prosecuting a vigorous study in each county of the entire country in order to determine the prevailing need for medical and preventive medical service, where such may be insufficient or unavailable. In other words, it is fulfilling its mission in a way characteristic of the doctor, the American public being the patient and organized medicine being the attending physician. When careful search has revealed the diagnosis, appropriate treatment will be applied. Efficient and ethical means can then be devised for the distribution of medical services to all people on the basis of need rather than to small groups within the population according to political expediency or special interests. Thereby it becomes possible for organized medicine to act specifically as a clearing house in the initiation, development and functioning of what may well evolve into a comprehensive system of medical care for all the people according to the American plan of medical practice.

THE AIMS OF THE MEDICAL PROFESSION

The aims of the medical profession as they relate to the public may be briefly summarized:

1. Maintenance of the present high standard of medical education, affording assurance that the graduate is competent to care for the sick.

2. Adequate provision for graduate education, with specified training for the development of specialists, and continued training for those who are not specialists so that the level of professional efficiency may be raised.

3. Extension of public health and preventive medicine to cover the field adequately.

4. Continuation of the practice of ethical scientific medicine on its present high plane.

5. Protection of the public against medical frauds falsely labeled foods, drugs and appliances.

6. The widest possible dissemination of health information to enable the public to act intelligently in the preservation of its health and in the prevention of disease.

7. The development and consummation of plans for extension of medical service to all groups of the population consonant with our established high standard of quality.

321 West Broadway.

IMPORTANCE OF RESTORATION OF BLOOD SUPPLY IN FRACTURES OF NECK OF FEMUR

FRED H. ALBEE, M.D., Sc.D.

NEW YORK AND VENICE, FLA.

The subject I have chosen for this paper is the question of blood supply in fractures of the neck of the femur. Because of the possibility of inadequate blood supply, it is my belief that the treatment of this fracture is a special problem differing from that of all other fractures. It is the most unfavorable of all fractures as to union, so unfavorable that Dr. Kellogg Speed of Chicago, when invited to deliver an oration on fractures before a recent congress of the American College of Surgeons, chose this particular fracture as his subject, designating it "the unsolved fracture." It may also be noted that Sir Ashley Cooper went on record as having said that he had never seen a fracture of the neck of the femur that had united.

The British Commission on Fractures has reported 22 per cent of union in all types of treatment of fractures of the central neck of the femur. In 1929 and 1930 a committee of the American Orthopedic Association studied this problem, making a survey of certain clinics in which as low a figure as 30 per cent of union was claimed. Two hospitals in New York have within the past four months announced statistics showing 38 per cent of union, while a third hospital reported 46 per cent. In this connection, a point worthy of note is that all three hospitals reported 20 per cent of aseptic necrosis of the head in cases coming to union, to such a degree that the condition simulated osteoarthritis with flattening and mushrooming and with symptoms so acute that in most cases arthrodesis of the joint was necessitated. Therefore, even when union is effected, the question is still unsettled as to whether the blood supply to the capital fragment is sufficient to prevent aseptic necrosis.

In 1902 Murphy first published statistics concerning the use of his metal nail as a fixation agent. It was a good, well machined square nail and superior to some varieties of recent origin. Since I began practice in 1904 many patients have come to me for treatment of nonunion after this and other types of nails had been used. Eventually this nail went completely out of use and was practically forgotten, until twenty-five years later, when an avalanche of nails, bolts, needles and screws of multitudinous variety appeared. Recorded experiences such as these and many others have resulted in much discussion of this subject in medical and surgical circles.

It would indeed be difficult today to catalogue all the types of treatment recommended for fractures of the hip. In general, they may be classified under two headings: the conservative, or nonoperative, and the operative. In the former category one may mention the names of Whitman, Leadbetter and Maxwell Ruth among others. The latter category can again be divided according to the different applications of metal gadgets used for internal fixations. One of these, recently announced by Dr. Morrison, is extremely clever and ingenious. It consists of a bolt or big nail with an internal contrivance inside that leads to the head of the bolt; after insertion into the head of the femur the extreme end of the bolt can be opened like a small

umbrella, thus insuring firm fixation into this fragment; the fragments are then firmly approximated by twisting the screw at the proximal end of the bolt.

The crux of the situation is that members of the profession have failed to recognize the fact that a subcapital fracture of the hip is a different problem from that of other fractures and, in failing to recognize this, they have assumed that mere reduction and maintenance of the fragments in position were all that was required. For nearly twenty years I¹ have contended that this was not all but that there were other factors entering into this particular fracture problem. A study reveals an unusual situation, the importance of which, strange to say, has never been appreciated, considering that success or failure of treatment depends on the recognition and overcoming of the difficulties disclosed. The capsule of the hip joint is attached to the neck of the femur obliquely and close to the base of the neck, and therefore a subcapital or central fracture of the neck of the femur is completely intra-articular. If it is completely intra-articular, then all possible sources of blood supply coming to the fragment of the head from the trochanter region of the femur or distal to the joint are cut off. This being so, the ligamentum teres can be the only remaining source of blood supply. The question then arises as to whether the ligamentum teres does in all instances, when not torn, provide an adequate source of blood supply. Wolcott and others have attempted to evaluate this by injecting the blood vessels of the ligamentum teres with mercury in cadaver specimens. This research has proved extremely interesting. In 15 per cent of cases Wolcott could not find blood vessels in the ligamentum teres of sufficient size to allow mercury to flow through them into the head or neck of the femur, and Henderson claims as high as from 20 to 25 per cent. So much for this.

The next question to be considered is the possibility of the ligamentum teres or its blood vessels having been destroyed by the trauma producing the primary fracture, and in this regard there are some very important observations not to be overlooked.

During the past twenty-five years I have performed 413 reconstruction operations for nonunion with marked absorption of the femoral neck and have in each case removed the head of the femur. Some of these were during the period of my service in the Great War. A careful check was always made by myself and my associates of the condition of the ligamentum teres at the time of the operation, and it may seem surprising that in 411 of these cases we found not the slightest evidence of bleeding at the cotyloid notch where the ligamentum teres is inserted into the acetabulum, which would have occurred if the ligament had been evulsed or torn at operation. In more than 70 per cent of cases, all ligamentous tissue appeared to have been evulsed from the cotyloid notch; in the remaining cases tabs of ligamentous tissue were found attached to the cotyloid notch of the acetabulum and fovea of the head of the femur or both. In two cases the ligamentum teres was found intact. In one of these the fracture was found to be at the center of the neck and due to a rifle bullet which was discovered at operation between the ununited fragments. The thought occurred to me that, since the neck of the femur was severed by a bullet, it might at the time have produced shock with its resultant muscle flaccidity. Therefore the muscle spasm incident to the usual fracture did not occur and

force the distal fragment of the femur upward, thus rotating the head in the acetabulum upward on the outside and the fovea of the head downward on the inside, to such a degree as to tear or evulse the ligamentum teres (fig. 1). This assumption is strengthened by the fact that the capsule is loose and alone determines the extremes of motion of the joint when the bony framework of the joint is intact.

It is believed that the rotation of the head which tears the ligamentum teres is brought about by the concerted spasmodic contraction of two powerful groups of muscles at the time of fracture. While the inward and outward rotators of the hip pull mesially on their osseous insertion (the great trochanter), holding the fracture surfaces of both capital and distal fracture fragments together, like the cogs of cog-wheels, at the same time the more powerful muscles force the distal fragment upward, rotating the fracture end of the spherical capital fragment upward and the fovea side of this head fragment downward, in this way tearing or evulsing the ligamentum teres.

Fig. 1.—Diagram showing direction of forces which produce rotation of capital fragment with resultant rupture or shearing of the ligamentum teres. Arrow at C indicates femur forced upward by trauma or muscle spasm, or both. Arrow at B indicates direction of rotation of head by the displacement upward of the femur because of contact of fragments at A, which is brought about by spasmodic pull of inward and outward rotator muscles on the trochanter in the mesial direction, as indicated by arrow D.

The anatomist Frederick Henry Gerrish² makes the following statement:

The ligamentum teres (round ligament) is not round, but a triangular, flat interarticular band attached by its apex to the upper half of the depression on the head of the femur, and by its base to the transverse ligament and the margins of the cotyloid notch, the ischial portion being the stronger. It is surrounded by synovial membrane, and represents a migrated portion of the pectineus muscle. It conveys a small branch of the obturator artery to the head of the femur. It is torn in dislocation of the femur.

The ligamentum teres is put on the stretch in flexion with abduction or outward rotation, or both, but it is too weak to be of use in resisting these movements or in strengthening the joint.

Dr. Henry Gray³ writes as follows:

The ligamentum teres femoris is a triangular, somewhat flattened band implanted by its apex into the anterosuperior part of the fovea capitis femoris; its base is attached by two

2. Gerrish, F. H.: *A Textbook of Anatomy*, Philadelphia, Lea Brothers & Co., 1899, p. 232.

1. Albee, F. H.: *Orthopedic and Reconstruction Surgery*, Philadelphia, W. B. Saunders Company, 1919.

bands, one into either side of the acetabular notch and between these bony attachments it blends with the transverse ligament. It is ensheathed by the synovial membrane, and varies greatly in strength in different subjects; occasionally only the synovial fold exists, and in rare cases even this is absent.

Still another authority, Dr. Gwilym G. Davis,⁴ may be quoted in this connection:

The ligamentum teres is composed of synovial and connective tissue. It is not strong and ruptures at about 14 kilos (30 pounds); the small artery it contains affords nourishment for itself alone, only a very small amount of blood going to the head of the femur. Bland Sutton regards it as a vestigial structure and a regression of the pectineus muscle. It is too weak to add much to the strength of the joint, and the view of Allis that its function is to distribute the synovial fluid and act as a lubricating agent is probably correct. The great pressure to which the articular surfaces of the hip joint are subjected requires special lubrication and this is furnished by the ligamentum teres and haversian gland.

From these studies, it is deduced that in the 411 cases of subcapital fracture the weak ligamentum teres

Fig. 2.—Diagram to show contrast with conditions in figure 1. In this instance, in which the fracture is at the base of the neck, rotation of the capital fragment to the degree of destruction of the ligamentum teres is prevented by the impingement of the outer portion of the neck of the femur at C against the rim of the acetabulum.

was destroyed by torsion or rotation incident to the explosive displacement at the time of fracture. The extreme force either evulsed the ligamentum teres from the acetabulum or head of the femur (more frequently it is the former) or ruptured the ligament by a twisting or shearing motion. After many months, or, as is often the case, many years, it is difficult to deduce accurately the circumstances associated with the destruction of the ligamentum teres. Varying degrees of fibrous adhesions to the periphery of the head are sometimes found, but, when severed in removal of the head, they have never been found to bleed to any appreciable extent, thus indicating that they have not been a source of blood supply to the capital fragment.

If this ligament has not been ruptured, there is every reason to believe that its continuity would serve to conduct induced collateral circulation to the capital fragment, even if anatomically the blood vessels were very meager in it.

It is my firm belief that in those cases coming to nonunion the destruction of the ligamentum teres at the

time of the fracture is the determining factor in the prevention of union. In other words, one is justified in coming to the conclusion that, when the ligamentum teres is destroyed, under such conditions the capital fragment becomes practically a joint mouse. Because of the intervening joint cavity, no blood supply can come to it, as in other fractures from adherent overlying muscles or soft parts. The fracture is wholly within the hip joint with very little soft tissue at the point of the fracture other than the torn synovial membrane on the neck itself.

A case bearing on this problem is under my observation at the present time:

The patient sustained at different times fracture of each hip. At the time of the first fracture, that of the right hip, there was no treatment at all. The patient lay in bed for a while and the hip united satisfactorily. Four years later the patient suffered a fracture of the left hip. It was treated and put in a Whitman spica cast by a competent surgeon, and roentgenograms taken at the time indicated excellent apposition of the fracture fragments. Nonunion followed, and fourteen months after the time of fracture the patient was seen by me and a reconstruction operation was performed. The capital fragment was removed, a wedge being made of it to reconstruct the lever at the top of the femur. On removal of the head it was found that the ligamentum teres had been destroyed.

The point to be emphasized in this case is that when the right hip was fractured the ligamentum teres probably was not destroyed and therefore union took place. When the left hip was fractured the ligamentum teres was probably torn, thus causing the blood supply to be cut off from the capital fragment and so, in spite of efficient Whitman treatment and immobilization, the fracture did not unite.

It can be further deduced that it is only in central or subcapital fracture that the mechanics is such that the capital fragment is permitted to rotate under the superior edge or roof of the acetabulum. When primary impaction occurs, there naturally cannot be extreme rotation or twisting of the head; therefore the ligamentum teres does not become torn or evulsed. This undoubtedly is one of the principal reasons, if not the determining reason, why such fractures are much more favorable to union. By the same token, it does not follow that secondary artificial impaction by the surgeon is of the same value because rupture of the ligamentum teres may already have taken place. When the fracture occurs farther out in the neck of the femur, especially when it is transtrochanteric, the fragment is so long that it cannot become rotated or twisted under the rim of the acetabulum (fig. 2); therefore the ligamentum teres does not suffer. Also if the fracture is so far out that it is partly or completely extra-articular, the adherent soft parts to the distal end of the capital fragment will prevent its rotation or torsion to such a degree as to rupture the ligamentum teres and also serve to convey blood vessels to the fracture junction of both fragments. There is thus a double reason for the tremendously increased difference in the percentage of union of such fractures as compared with the subcapital variety.

Realizing these facts, I worked out the use of the bone-graft peg in the treatment of ununited fractures and some years ago published statistics showing about 94 per cent successful results. About the same time Dr. Willis C. Campbell, using the same method, published statistics that were even better than mine. The significance of these results is extremely important, since Dr. Campbell and I were dealing with cases much more unfavorable than fresh fractures, first,

4. Davis, G. G.: *Applied Anatomy*, Philadelphia, J. B. Lippincott Company, 1913, p. 507.

because they were nonunions, or pseudo-arthroses; second, because the capital fragment had become practically a joint mouse, and, third, because the urge of primary repair had long ceased to exist.

It is further interesting to note that, through a fault in technic on my part in failing to approximate the fragments in three of these cases, we learned something of great significance concerning the function of the autogenous bone-graft peg. (When inserting the peg, I always attempt to impact the fragments.) In these cases the hiatus between the fragments (varying in extent from one-half to two-thirds inch) was spanned within the joint by the bone-peg alone. X-ray study of these cases at a later postoperative date showed that the peg constantly increased in size to the degree that it finally filled in the hiatus completely and that, in spite of the fact that the fragments were separated and the peg was situated in the joint cavity, blood vessels extended through it from the trochanter fragment to the capital fragment, the peg by its inherent osteogenesis having filled this space between the fragments with resultant union. The importance of this observation is self evident as showing the potentiality of the bone-graft under most unfavorable conditions. It is interesting to consider what would have happened had a metal agent been used. In this respect, however, it should be commented that in many instances I have observed that a graft has filled in spaces many times more extensive than in the cases cited—even to as much as sixteen times the dimension of the hiatus in any one of the cases, the only difference being that the long grafts were surrounded by soft tissue instead of spanning a joint space.

About four years ago Scudder, who is an authority on fractures, realized the importance of this question of blood supply in fractures of the neck of the femur and, in discussing a paper by Dr. Moorhead, suggested that the capsule be incised and the muscle tissue brought through the rent in the capsule into the hip joint, thus being brought in contact with a freshened surface of the capital fragment in order to bring blood supply to this fragment. This suggestion, to fill a part of the joint space with muscle by contact with the freshened areas, in the hope of bringing blood supply to the anemic head, does not seem very feasible. One approaches this suggestion with skepticism for the very pertinent reason that muscle tissue, even when temporarily cut off from the blood supply, changes to connective tissue, as is so well demonstrated in Volkmann's ischemic palsy. In fact, during the last twenty years I have seen several cases in which muscle tissue has proved to be the most unfavorable of all tissues to withstand temporary or prolonged loss of blood supply. In this connection one could cite cases of emboli, thrombosis and accidental severance of an artery; also extreme cases of interruption of blood supply from fractures such as at the elbow, where, instead of Volkmann's palsy with muscles turning into connective tissue, they merely sloughed. In all these cases the muscles were pulled out through the skin, which, as well as the bone and other structures of the extremity, had retained its vitality. The blood supply would indeed have a better chance of being reestablished after temporary anemia had been relieved in the muscles of the forearm than would be the case if a piece of muscle were pulled through a rent in the capsule of the hip.

Bone, being a supportive and relatively undifferentiated tissue, is able to suffer the absence of its blood supply for a considerable time without adverse effects

for the reason, among others, that it is extremely favorable for transplantation. The rapid and profuse vascularization of a bone-graft is one of the most striking features encountered. When a portion of the complete diameter of a long skeletal bone has been replaced by massive grafts of much smaller diameter, not only will the whole shaft be restored to its complete diameter and strength but also a completely vascularized marrow cavity will develop. The same phenomenon occurs in the use of a bone-graft as a terminal structure, such as in building digits, in which a tibial bone-graft is inserted into a tubular skin graft to restore a finger or thumb, which I have done many times. In this instance there is a physiobiologic demand for blood at the distal end of this bone-graft and in response a collateral circulation is developed in the whole length of the graft to the degree of a marrow cavity with its incident blood vessels. The analogy is identical to that of the peg graft conveying blood to the anemic femoral head from the very vascular cancellous tissue of the trochanter. These characteristics, as well as the osteogenic capacity of the autogenous bone-graft peg together with its mechanical strength (for immobilization purposes) determines it to be the ideal means of treatment in operable cases of both fresh and ununited fractures of the central intra-articular portion of the neck of the femur. It is the only answer to the tripod of necessity in the treatment of such fractures, for it first furnishes immobilization and, second, a living scaffold for vascularization to the anemic head fragment, and, third, it brings an osteogenic, callus-forming material to the fracture junction.

Sir Arthur Keith, the practical pathologist of England, has prepared an extensive number of specimens that are on exhibition in the Museum of the Royal College of Surgeons in London. The study of these specimens is most profitable. They are prepared and injected to show the profuse vascularization of bone grafts in general. In putting in bone grafts to take the place of portions of shafts of bone, my own experience has in many instances confirmed Sir Arthur's observations. These cases, which have been studied over a period of years, both by x-ray and by laboratory means, have demonstrated profuse vascularization and even the formation of a marrow cavity.

After most operations the period of immobilization in double plaster of paris spica casts is twelve weeks. The callus-forming capacity of the bone during that time is so low that one must allow a generous period of time for this to take place. Whether the bone-graft peg operation should be performed as the primary treatment is for the surgeon and his patient to decide. Some patients, of their own volition, have requested the operation.

To recapitulate, it is of great importance with every type of treatment, especially when any of the various kinds of metal fixation agents have been used, for the surgeon to be eternally vigilant in watching for the earliest evidence of the beginning of nonunion. If there should be any change of position in the relation of fragment to fragment, even of the slightest degree, this is evidence that union is not taking place. Very soon proof will follow with bone absorption at the neck of the junction of the fracture, indicating that there is an inadequate or total lack of blood supply and also that the ligamentum teres may have been ruptured or destroyed by a twist or rotation of the head at the time of fracture. In the latter event the capital frag-

ment is essentially a joint mouse. Under such conditions, if union is to be secured, immediate action is urgent. With the fragments in good position, a bone-graft peg of at least one-half inch diameter should be obtained, preferably from the crest of the tibia, and should be immediately inserted.

PSYCHOSIS AND THE CENTRAL AUTONOMIC NERVOUS SYSTEM

H. DOUGLAS SINGER, M.D., F.R.C.P. (LOND.)

CHICAGO

In the study of patients with so-called mental diseases it has been perhaps inevitable, because of its prominence and overt expression, that primary emphasis should have been accorded to the form, or content, of the psychosis as a means of differentiating nosologic entities. Much admirable research into physiologic disturbances occurring as symptoms in mental illnesses has, however, rendered little service to their elucidation, mainly for the reason that the correlations which have been attempted are between the symptoms of the illness, on the one hand, and the person who is ill, on the other. It is my purpose in this article to present considerations for a reorientation of point of view, not with the object at present of propounding a new system of classification, for which there is yet insufficient knowledge, but as a guide to the analysis of clinical material and the prosecution of research.

It will probably be conceded without question that what underlies mental illness is some disturbance, due either to structural lesion or to situational stress, in the central integrating mechanisms of the organism.

DISTINCTION BETWEEN ILLNESS AND PERSON WHO IS ILL

In analyzing any case of mental illness clinically, there are two groups of factors to be considered: (1) the nature and location of the illness, and (2) the personality of the person who is ill. A structural lesion of the nervous system gives rise to symptoms which depend on the location of the lesion; these are necessarily primary disorders in physiologic activity. The form and character of the adjustments that the patient will make under the conditions of the illness, however, depend on his personality—his persistent habits of adjustment.

To illustrate this statement, reference may be made to disease processes of known character; for example, in dementia paralytica it has long been accepted that the cerebral lesions give rise directly to well recognized disorders of function which depend on interruption of corticospinal cerebral pathways—the various manifestations known as dementia, aphasia, hemiplegia, and so on. Symptoms of this type are present in every case of dementia paralytica and depend for their appearance on the location of the lesions. At the same time there may or may not be present a psychosis, the meaning of which as a descriptive term will be more fully discussed later. At this point all that is necessary to indicate is that the “form” of the psychosis does not depend on the nature of the illness but is derived from the personality of the person who is ill. The “form” of psychosis, when one occurs, may be an anxious depression, a manic excitement, a schizophrenic syndrome or a paranoid state. To correlate the various physiologic disturbances revealed as dementia, for example, due to

the cerebral syphilis with the “form” of the psychosis will generally be conceded to be impossible. And yet this type of correlation is adopted in what are commonly called the “functional” psychoses—those in which at present the lesions, when they exist, have not been defined or discovered.

Reasoning by analogy, it seems permissible to conclude that in all psychoses, just as in those which accompany such structural lesions as those of dementia paralytica, cerebral arteriosclerosis or toxic delirium, the form of the psychosis, no matter what the nature of the illness, depends on the personality of the person who is ill.

The criteria to be used for a pathologic diagnosis, on the other hand, as in dementia paralytica, are the modifications in function caused by the lesion. This means that in order to diagnose the presence, nature and location of a lesion in any case of mental illness one must search for evidence of what functions are damaged or are lost and what remain intact, regardless of the particular pattern of expression usual to the patient—that is to say, whether an existing psychosis is of the manic-depressive, schizophrenic or paranoid form. If there is a structural lesion, the symptoms of altered function are essential or primary and will always be present, like the dementia in dementia paralytica; they should be particularly well defined and indicative of location in the final stages of the illness in cases in which permanent damage occurs.

THE MECHANISMS OF INTEGRATION

The central integrating mechanisms of the body are commonly grouped for convenience under two main headings: the cerebral pathways (corticospinal) concerned in symbolic representation, and those commonly described as autonomic. As regards the afferent paths of these two systems, the former come especially from the more highly discriminative organs of special sense and the latter from organs concerned in vegetative and primitive defensive reactions. Each system has its own set of efferent pathways and effector organs. There are also cerebral association pathways connecting the two in both directions. Using commonly accepted psychologic terms to describe the two systems, it is permissible to speak of the first as dealing with “intelligence” and the second with “affective” types of response.

The manifestations of damage in the central corticospinal integrative mechanisms have been comparatively well defined. Expressed briefly, they include disturbances in the reactions associated with consciousness and are evinced in the forms of illusion, dementia, disorientation and defects in action of the type of apraxia. In addition to the ordinary methods of neurologic investigation of lower level disturbances of function in this system there are available various “tests” for higher level disturbances in apperception and intelligence tests of various kinds. Such tests are continually being improved and refined and are fairly reliable, though complicated in interpretation by such problems as attention and distraction. They reveal evidences of dysfunction in most cases of recognized disease processes within the corticospinal system, and one does not hesitate clinically to postulate from the symptoms observed the presence of lesions and their location even when one does not know their nature.

Numerous researches with these methods of “testing” have been carried out in cases of “functional” psychoses. While there are some not fully explained exceptions, it seems justifiable to assert that almost always they have yielded negative results. Hence it may be concluded

that damage in the corticospinal system is at least not a principal feature of these forms of illness.

The foregoing statement applies not only to the manic-depressive psychoses but also to those of schizophrenic or paranoid type. Kraepelin,¹ who adhered rigidly to facts of observation, stated that dementia praecox is "a peculiar disturbance of the inner coherence of the psychic personality with outstanding damage in the realm of mood and in volition." Furthermore, in describing the terminal states of deterioration which frequently occur, he said ". . . the clinical picture is dominated sometimes more by poverty of ideas, sometimes more by emotional dullness and sometimes more by some one of the peculiar disturbances of volition." These statements both express the conclusion that there is essentially a disturbance in energy and the affective life. A similar description could be given of the terminal state in other psychoses; for example, in the deterioration observed after presenile psychoses (spätkatatonie) and after frontal lobectomy. These considerations at once suggest that the essential structural damage in the "functional" psychoses, including dementia praecox, when present, lies not in the "intelligence" or corticospinal regions of the brain but in the central autonomic or "affective" integrating machinery. Study of the life histories of many, but by no means all, patients with dementia praecox and of the manifestations of the illness, especially in its terminal stages, points in the same direction. Most of the research in dementia praecox today is directed toward the study of autonomic functions. This feature has been emphasized by many investigators, and yet there seems to be an unwillingness to carry the observations to a logical conclusion. So much attention has been focused on the "schizophrenia" (a term which I understand as meaning the form of the psychosis) that the significance of the "dementia praecox" (a term that may well be used to express a pathologic lesion) is overlooked.

It should be stressed that the point of view here outlined does not apply alone to schizophrenia, even though I have used illness manifesting itself in this form for purposes of illustration. One reason for making this selection is that the schizophrenic form of psychosis presents such striking evidences of distortion of thinking and action that one is almost inevitably led to postulate change in the central corticospinal neurons. It is my principal contention that it is the fact of psychosis alone that is determined by the pathologic lesion, and that the form or content of the psychosis is determined by the personality of the patient. It is not without significance that in the discussion of cases there is frequently a diversity of opinion as to whether a psychosis is of manic-depressive or of schizophrenic form; combinations of these two forms, often with more or less admixture of paranoid features, are so common as to be almost the rule. It may be suggested that a similar difficulty is experienced in attempting to classify people by personality as syntonie or cyclothymic, on the one hand, and schizoid on the other. It is always a problem not of all or none but of more or less. If I am correct in stating that one form of lesion may give rise to a schizophrenic psychosis in one person and to a manic-depressive psychosis in another, such differentiations have little importance medically. This is not intended to imply that study of the form

of psychosis should be neglected. Indeed, a psychosis, outcome of an experiment of nature, presents the facts of modes of adjustment in such exaggerated form that it furnishes extremely valuable information for use in the study of personality and the psychoneuroses.

The foregoing considerations lead me to the conclusion that the presence of a psychosis always indicates disturbance in central autonomic integration, no matter what the pathologic nature of the cause. It may be unnecessary but seems wise to emphasize that the corticospinal and the autonomic systems may both be damaged by some lesions. When this occurs, as in dementia paralytica, for example, there will be symptoms belonging to disturbed functions in both systems.

PSYCHOSIS AND PSYCHONEUROSIS

While it has little bearing on the thesis of this article, it seems advisable to comment on the current use of the terms psychosis and psychoneurosis. I know of no satisfactory definition of or means of distinction between these two terms, and one encounters even such statements as that psychoneuroses are "minor psychoses." This lack of clarity in the use of these terms is an unquestionable source of confusion. In order to overcome this difficulty, I propose to define these two terms as follows: A psychosis is a pathologic state of mind brought about by structural lesion of the central autonomic nervous system; a psychoneurosis, on the other hand, is a disturbance in adjustment to the problems of life, no matter how severe. The former arises from causes within the organism of a structural nature; the latter arises primarily from extra-organismal or interorganismal relations, and the liability to its occurrence is dependent on the constitutional endowment of the patient at the time.

It is not my intention to make an issue of this question of defining terms, but I submit that the meaning here offered has a practical bearing on the understanding of mental illnesses and the selection of the appropriate therapeutic approach. Used in this manner, the term psychosis is not a substitute for the legal term insanity (a sense in which it is often used) but implies the presence of an organic lesion even if the nature of the lesion is not known. Furthermore, a psychoneurosis may be so severe that the patient is committably "insane."

From these considerations it is evident that a new grouping of mental illnesses must be undertaken. With the psychoneuroses would be included the conventionally accepted reactive depressions and elations, and cases of what today are called schizophrenia but which are essentially reactive conditions of psychogenic nature.

AUTONOMIC INTEGRATION AS CONSTITUTIONAL ENDOWMENT

In the evaluation of constitutional endowment, too little consideration has been given to the problem of energy endowment. The energy of the organism undoubtedly arises ultimately from the metabolic activity of the individual cells of which the organism is constructed. Regulation of the metabolic activity, and hence of the quantitative output and direction of flow of energy, is a function of the autonomic system, in which are included the endocrine glands, and this is integrated through the central autonomic nervous system.

While satisfactory means for the accurate measurement of energy capacity are not available, it is possible to estimate this factor by a study of the life history of the patient through forcefulness of active adjustment

1. Kraepelin, Emil: *Psychiatrie*, Leipzig, Johann Ambrosius Barth, 1913, vol. 3, p. 668: ". . . eine eigenartige Zerstörung des inneren Zusammenhanges des psychischen Persönlichkeits mit vorwiegender Schädigung des Gemütslebens und des Willens." P. 880: ". . . in denen bald mehr die Verstandesschwäche, bald mehr die Gemütsstumpfheit, bald mehr eine der eigenthümlichen Willensstörungen das Zustandbild beherrscht."

or a tendency to retire into wishful thinking, the reactions of the body to toxins and infections and the types of associates and of vocation and avocation, for example. The energy of the organism does not correlate with intelligence. Energy may be severely defective in a person with superior intelligence quotient; the reverse is also observed. Doubtless in this, as in other bodily functions, there is a range of what may be considered normal energy (in the sense that the energy is sufficient to allow adjustment to average life difficulties). Even with average energy endowment, however, greater thwarting from particularly difficult situations may still give rise to poor adjustments, or psychoneuroses.

PATHOGENIC POSSIBILITIES

1. *Organic (Psychosis).*—Like other organs and systems of organs, the nervous system is liable to such lesions as toxic and infectious damage, trauma, neoplasms, degenerations due to defective blood supply, senility, dietary deficiency and other causes. When

The Nature of Disturbance in the Central Autonomic Nervous System in Relation to the Conventional Classification of Mental Illness, Mainly on the Basis of the Personality of the Patient

The Illness	Some Conventional Designations
Primary defect conditions..	Dementia simplex type of schizophrenia; psychopathic personality; some neurasthenias
Toxic and infectious lesions	Delirious psychoses; acute hallucinosis; manic-depressive, schizophrenic and paranoid psychoses and emotional deterioration following epidemic encephalitis, or associated with pellagra, dementia paralytica, and the like
Traumatic lesions.....	Psychoses associated with trauma of the head; the traumatic constitution
Degenerative lesions.....	Psychoses and affective defects with involutional melancholia and other presenile conditions, with senility, with arteriosclerosis, and so on
Lesions of unknown nature	Many schizophrenias, particularly those of catatonic form; some manic-depressive and paranoid conditions
Disorders in homeostasis...	Constitutional types of manic-depressive psychosis and some schizophrenias of cyclic form
Situational reactions (without structural lesion)	Most psychoneuroses; some manic-depressive, schizophrenic and paranoid psychoses

such lesions involve the central autonomic nervous system a psychosis—characterized by increase or diminution in the output of energy—will occur.

A particular group of psychoses, sometimes of manic-depressive, sometimes of schizophrenic, form appears to be associated with defective organization of the integration of what Cannon has called homeostasis. Since these are periodic in their appearance it seems at least probable that there are precipitating factors of unknown but possibly sometimes of organic nature which do not give rise to irreversible changes in the nervous system.

2. *Primary Defects.*—Ageneses and defects caused by lesions occurring early in life are well known in the cerebral corticospinal system and are known clinically as mental deficiency. It is postulated that similar defects occur in the central autonomic nervous system. These are expressed in the form of defective energy of reaction, low levels of metabolic activity, and so on, and have already been discussed under the heading of constitutional endowment.

3. *Reactive (Psychoneurosis).*—As already indicated, these are adjustments of the organism to situations of difficulty and thwarting. However, as an essential part of the causation there is a relative weakness of autonomic construction, relative in the sense of a relation between the energy available and the severity of the difficulty giving rise to the adjustment.

While psychoses and psychoneuroses are thus defined as presenting essential points of difference, it must not be inferred that they are mutually exclusive. Combinations of the two types of factor are common in clinical experience, and careful analysis may be needed to evaluate the importance of each and thus to determine the proper therapeutic approach.

The accompanying table will indicate, in a general way, the regrouping of cases that emerges from the foregoing considerations. Damage in the corticospinal integrative mechanisms has been omitted from the table for the reason that the symptoms produced are commonly recognized and adequately evaluated. It should be stressed, however, that one and the same disease process may affect the two integrating systems, as in dementia paralytica, toxic delirium or cerebral arteriosclerosis. A psychosis may thus be accompanied by evidences of disturbance of intelligence.

From the table it is evident that, when analyzed in this way, it has seemed possible to make some tentative subdivisions of the pathologically heterogeneous groups of the so-called functional psychoses. In illustration, the case histories in two examples of what were conventionally classified as schizophrenia are outlined and the differential points emphasized. One is a psychosis, the other a psychoneurosis as here defined.

CASE 1.—Conventionally classified as schizophrenia with some catatonic features. *Principal symptoms, disturbances of mood with progressive deterioration of interest and activity in a person with good intelligence and low average energy endowment. Diagnosis: structural lesion, nature unknown, in the central autonomic nervous system; schizophrenic psychosis.*

Prepsychotic History.—The family history was without especial taint, except that an older brother died of tuberculosis at the age of 25. The family was an unusually closely knit unit, apparently content to make few external associations. The early history of the patient is remarkable for lack of color in the personality. She was always healthy and had no serious illness. She was obedient and did not get into mischief, never requiring discipline; she was retiring and made few friends, prudish in dress and habits, did not smoke, drink or use cosmetics, and yet was not unusually religious. She was bashful with men and had no love affairs. She was thoughtful of others and meticulous in her work. After leaving school at the age of 17 she secured a position as a stenographer and remained with this firm for thirteen and one-half years until the time of the breakdown; she was promoted to the post of secretary to an executive officer, her maximum earnings being \$125 a month; she voluntarily gave her earnings to the mother.

The lack of forcefulness and expression of inner drives suggest that endowment with energy was somewhat below average, but adequate for the situation in which she lived and sufficient to enable her to pass through the period of adolescence without evident difficulty. The absence of severe illness indicates an adequate bodily defensive endowment.

Endowment with intelligence was certainly average and probably higher. She graduated from grammar school at the age of 12 years 2 months, having received double promotion from grade 6B to grade 7B. In high school she was considered one of the bright students of her year. Her only extracurricular activity in high school was working on the school paper; she had some stories printed. She always returned home promptly from school and worked in the family store. An intelligence test (Stanford-Binet) at the age of 31, three or four years after the onset of the illness, gave an intelligence quotient of 102, and the comment was made that this was probably at least 10 points too low.

Precipitating Factors.—Careful inquiry failed to reveal any change in the situation at home, at work or in the personal affairs of the patient.

The Psychosis.—The onset was insidious and the progress slow. Three years elapsed after the first changes were noticed before it was realized that there was something seriously wrong and the patient was sent home from the office. The early manifestations, at the age of about 28, were signs of irritability.

fatigue and increasing withdrawal from people. These were at first occasional and fleeting but slowly became more frequent and persistent. There also appeared evidences of a feeling of change and a depressed mood, with self blame. For example, she spoke of noticing a change in a younger brother, who had been probably her closest friend, and said that the change was due to poisoning because she had sterilized some instruments in an antiseptic solution when the brother had diphtheria three years before. She began to speak of being observed by people, particularly colored people, on the streets, that her home was under surveillance and her father wanted by government men. At the office she became argumentative, even at times impertinent. Sudden impulsive actions, without apparent motive, were observed both at home and at work. For example, she would suddenly leave the room, walking hurriedly, and be found rocking furiously in a chair or staring through a window, seemingly perplexed and oblivious of her surroundings; on one occasion, three years after the onset, she jumped out of bed in the middle of the night and started to play the piano. When questioned about this episode she said that a voice had ordered her to play and sing; other evidences of hallucinosis were not observed at any time. With these erratic and somewhat explosive disturbances of mood, which became gradually more prominent, there appeared evidences of loss of interest; she became careless of appearances and, though she had been a prude, would wander around the house nude.

The patient was under observation at the Psychiatric Institute for about fifteen months, when her age was 31 and 32. During this period she was most of the time inactive and indifferent, but there were occasional spontaneous spurts of increased activity, in some of which she was even playful and interfered with other patients. Most often she resisted in routine activities, such as eating, bathing and dressing. The resistance was often negativistic; for example, she might do no work in the occupational department but begin to work rapidly when the call to discontinue was made; when asked to do something she might not comply but suddenly perform the task if someone else was asked to do it. At times she assumed awkward postures, such as standing on one foot with the other raised, and maintained this posture for as long as ten minutes. Occasionally she was violent; she threw dishes at a patient who took some bread from her tray. Her voice was most often so low as to be almost a whisper; at other times it was almost a yell. She was negligent and careless in dress and attention to excreta.

Mental content as revealed in what she said and did appeared to be as colorless as the story of her prepsychotic life. She was formally well oriented at all times and the comment was made that her speech utterances were grammatically correct. Memory, as far as could be investigated, was good; she spoke of incidents in another hospital, recalling the names of nurses and physicians. Frequently there were expressions of a feeling of change and domination, with depressive content. She said, for example: "I feel a goner; I don't want to ruin any of your lives; I don't want to hurt any one; there is a change in me; I have no respect, no love; do you think I am dead? Death is coming; I am afraid of death." "I want to come but something keeps me from coming; I can't help it; I want to eat, I'm not really stubborn, but I just feel that something holds me, I can't help it."

Following a period of *dauerschlaf* from administration of sodium amytal there was a brief period of improvement. The patient became more active and responsive. She said spontaneously that she felt better and asked for the physician by name, saying that she wished to go home. "I feel well enough to go." She assisted the nurse with some ward work and said "May I wash those cups for you? They are greasy and you will get it all over your hands, and it will give me something to do."

Physical examination revealed little of significance. There was severe acne of the face. A roentgenogram of the chest was normal in appearance, in contrast with the fact that about two years later a film made at the Chicago State Hospital presented definite evidence of tuberculosis. Laboratory studies yielded results that were all within normal range. The blood pressure was 124 systolic and 88 diastolic; the basal metabolic rate was +1 and -16, respectively, on two occasions. Studies of the blood pressure and electrical resistance of the skin under various forms of stimulation revealed changes which will not be discussed at this time.

On a number of occasions there were observed some peculiar attacks lasting approximately ten or fifteen minutes. The attack would begin with rapid deep breathing, the eyes being closed, and after a short time would seem to reach a climax with a deep breath, when she moaned and slipped gently to the floor or back in a chair; she then appeared stuporous and limp but was not unconscious. There were no convulsive movements, but a tremor was observed in the entire body and the skin was bathed in perspiration.

On leaving the Psychiatric Institute the patient was transferred to the Chicago State Hospital, where she has been for the past year. Apathy and indifference have continued to increase. Activity is less than before, and as already mentioned there are signs of pulmonary tuberculosis.

The facts outlined seem to point, almost exclusively, in the direction of disturbance in autonomic integration. Studies of corticospinal functions reveal no evidence of damage; intelligence was fully average, with the tests used, even three or four years after the onset. In addition, the unusual occurrence of "attacks" of vegetative character has a similar significance.

The conclusion that the disturbance of autonomic integration is due to a structural lesion is based on: (1) a longitudinal review of the onset and course of the illness, early signs suggesting hyperexcitability in energy of response to situations that were apparently in no way changed, with progressively increasing signs of loss of energy (affective deterioration); (2) the absence of a relation of manifest ideational content with any consistent drive and its thwarting; (3) evidences of withdrawal from reality without indications of corresponding absorption in fantasy.

This case seems to present the evidences of vegetative disturbance in almost pure form; that is, uncomplicated by expressions of symbolic representation which would be expected in a person with more colorful personality and imagination. The case was selected for that reason; evidences of a richer fantasy life add a complicating factor which often renders differential analysis difficult.

Possibly it will be objected that this case is so evidently an example of structural lesion that the consideration of schizophrenia is unjustified. The case, however, is not unusual and it will be found on analysis that examples of this type are numerous. It may be added that this patient had been studied in three different hospitals before coming to the Psychiatric Institute and that in all the case was considered to be one of schizophrenia of catatonic type.

CASE 2.—Conventional classification, schizophrenia of hebephrenic type. Abrupt onset of adjustment by fantasy with striking symbolic expression in a girl, with good endowment but severely tainted heredity and extremely difficult home situation, following a love affair. Recovery without defect in about two years. Second breakdown after another love affair one year later. Diagnosis: Psychoneurosis.

Personal History.—The paternal family history is replete with examples of erratic behavior, mental illness and criminality, combined with high intelligence. The father was a drunkard and committed many sexual crimes. The mother, a talented musician, divorced the father and assumed a different name when the patient was about 10 and has since become the mistress of a man whom the patient calls uncle. The patient was healthy and had no serious illness; she is strikingly beautiful and has resented scars left by instruments used in her delivery and also myopia, which has necessitated wearing glasses since the age of 10. Menstruation started at the age of 13 and was accompanied by moodiness and a tendency to solitude; periods of depression and irritability have been frequent during the week preceding menstruation. At school the patient was always first in her class; she graduated from grammar school at 13 and from high school at 17. She was always anxious to succeed;

took everything seriously and worried greatly over examinations and other situations of responsibility.

As a child she had little association with other children. It is reported that she was devotedly attached to her father but after the separation of the parents, which was accompanied by a good deal of unpleasant notoriety, never spoke of him. Living alone with her mother after this, she was still more isolated; she was somewhat precocious and found it difficult to adjust to children of her age. The first year in a private high school, at the onset of puberty, was very unhappy; she made no friends and took no part in social affairs. She refused to return to this school and was sent to another private school for girls in her second year. There the picture changed completely; she became a leader, was extremely popular and active, and was thoroughly happy. She showed considerable talent in singing and dramatics. In the last year, at the age of 17, she had a mild love affair, which lasted three months, but she behaved quietly and sedately and showed no particular upset when it was broken off.

After graduating she held several clerical jobs for a short time but resented the monotony and spoke of a desire "to be somebody." She "had to be a lady" and "hated mediocrity." She sang over the radio, without pay, for three months but was dropped because she refused to change her style to suit the sponsor. During this period she maintained an active social life, entertaining friends and showing a good deal of independence. She also studied music and dancing. She wrote poetry with some evidence of ability but did not attempt to publish it. At times she expressed ideas of jealousy toward her mother and resented the mother's selection of her (the patient's) clothes; she commented on the mother's attractiveness and accused her of stealing her "beaux."

Precipitating Factors.—At the age of 19 she became infatuated with a music teacher, aged 35, who is said to have talked to her about sexuality and to have discussed homosexuality. She told her mother that she "worshiped this man" and when the mother told her to "keep her feet on the ground" the patient immediately became reticent and would say no more. The teacher had been giving the patient instruction on producing her voice "from the solar plexus."

The Illness.—The onset was abrupt, shortly after the incidents just mentioned. She began to speak in a deep voice and said it was necessary "to talk from the solar plexus" and "to try to use the solar plexus" in order to be clear. On the following day she was unusually quiet and careless of her dress; she went out and stayed away all day and would give no account of where she had been. The next day she refused to eat, did not speak and lay about carelessly. On the next day she lay around in her room nude, assuming a crucified posture for hours; she took out the window screens and opened the windows wide, saying, "You must not shut out God or God's air." She screamed "hysterically" when the mother attempted to expostulate with her. On the following day similar behavior continued; she hung her head out of the window in the rain and spoke of the need to have "God's rain" on her head to cleanse her; she accused the mother: "You condemned me." She was then admitted to the Psychiatric Institute.

When received, she appeared confused and showed evidence of dehydration and intoxication. These symptoms rapidly disappeared under forced feeding and she became active and restless, showing behavior that was unpredictable. Her manner was stilted and affected; sometimes she entered into games and occupational activities; sometimes she was irritable but never violent. Eating was capricious; often she ate in large mouthfuls, licking the dishes with her tongue, mixing the various foods and even stealing from others. She was coquettish, theatrical and flirtatious, often exposing herself in front of men, and professed to fall in love with the physician who had charge of her. She was often brazenly untidy, urinating and defecating on the floor and laughing loudly while doing so. Saliva was allowed to drool over her clothing. In spite of this behavior she was clearly oriented and fully in contact when she responded to questions, and sometimes expressed the thought "I want to be a lady."

Following a course of dauerschlaf with sodium amylal the patient became more communicative. She spoke of intense jealousy of her mother and said: "I took sick to bring her to her senses." "She persuaded me against men." "The air

around me was rotten. I had to breathe deeply to catch air in order to live in purity." "I broke down to clear my mother of her sins." "She always wanted me to have older men as friends and never of my own age. After a second course of dauerschlaf even more frank confessions of resentment toward the home situation were given. She commented on the immoral lives of both her father and her mother.

Subsequently she remained well in contact and the odd behavior rapidly subsided. She was allowed to return home at the end of two months. She remained well for two or three weeks; then there reappeared many mannerisms; she refused food and again became untidy and soiling in habits. She was then sent to a private sanatorium, where behavior similar to that already described continued for nearly a year. Much of the time she spoke only in broken English with a French accent—a symbol for her fantasies, as she later acknowledged. She also retained urine and feces—sometimes necessitating catheterization—and said that the excreta "belonged to her"; she defecated on paper and carried the excrement about, refusing to surrender it. In some of the remarks she accused her mother of homosexuality and bestiality. At other times she expressed a maternally protective attitude toward the mother. Improvement occurred gradually, with resumption of interest in sports and dancing. The patient appeared to gain full insight into the significance of the symbols she had used in her fantasies.

Subsequent History.—Arrangements were made for the mother and daughter to leave their home and to live separately in another state. Frank discussions were held with both, and there was a decided improvement in their attitude toward each other. The patient made excellent adjustment socially and secured work in which she was interested. Letters were received from both, recording increased happiness and satisfaction. This situation continued for more than a year, when another love affair disturbed the patient's balance. Unfortunately, she received advice from a physician which she interpreted as implying that her troubles would be cured by sexual intercourse. This advice was followed and resulted in another breakdown, from all accounts similar to the previous episode and without indications of deterioration of interest. This condition still exists at the time of the present report.

The report is much condensed and intended to show only the nature of the illness in broad outline. The facts given are sufficient to indicate the conflicts in which the patient lived—conflicts arising from ideals which had been painfully reinforced by the social attitude toward her family and by the teaching of the mother; strong sexual drives, stimulated by observations of the parents and particularly of the mother, and personal experiences in a somewhat bohemian atmosphere. The form of the illness exquisitely symbolizes the existing conflicts, and the outbreak, in both attacks, was precipitated by a situation of emotional stress. Throughout, except for the brief period of dehydration at the outset, the patient has remained clear and in contact with reality; there have been no evidences of corticospinal defect and no suggestions at any time of loss of energy. Even the untidiness with regard to soiling is evidently an active process of fantasy and adjustment and is not suggestive of defect in energy.

SUMMARY AND CONCLUSIONS

The term psychosis may profitably be used to designate active disorder in behavior resulting from structural damage of the central machinery of autonomic integration, specifically dynamic or "energy" disorders.

The term psychoneurosis may, in contrast, be used to designate maladjustments (psychogenic) to life situations and when used in this sense will include some examples of what today are grouped as psychoses; the behavior constituting a psychoneurotic adjustment may require commitment of the patient.

Examples of structural damage or defect, either congenital or acquired, in the central autonomic nervous

system include, as examples, schizophrenic dementia simplex, psychopathic personality, some forms of "neurasthenia," the "organic" psychoses, involutional melancholia, many manifestations of chronic encephalitis, and affective changes following frontal lobectomy. In addition, there belong in this group many of the so-called functional psychoses, whether manic-depressive, schizophrenic or paranoid in form, even though the nature of the lesion is unknown.

There is an essential difference between the symptoms produced by the illness, which includes the fact of psychosis, and those which express the form of the psychosis. The former are determined by the nature and location of structural damage and the latter by the personality of the person who is ill. Thus, one and the same organic lesion, even though its nature may be unknown, may give rise to a manic-depressive form of psychosis in one person and to a schizophrenic or paranoid psychosis in another.

The use of the form of psychosis as a basis of correlation with observed physiologic disturbances will yield little of value as regards the pathologic condition concerned in giving rise to the fact of psychosis. The form of the psychosis is of paramount value in the study of personality.

SEVERE REACTIONS FOLLOWING TRANSFUSION IN HEMO- LYTIC JAUNDICE

REPORT OF TWO CASES

JOHN C. SHARPE, M.D.

AND

HERBERT H. DAVIS, M.D.

OMAHA

During a recent study of a group of patients with hemolytic jaundice before, during and after splenectomy, we¹ have been disturbed on two occasions because of unfavorable reactions following transfusion of whole blood. A general review of the voluminous literature on hemolytic jaundice failed to reveal a single title referable to this complication, but submerged in the detailed study of case reports there are warnings of its occurrence and possibility. As a result of our experience, it seemed feasible to focus attention on the subject and to present the clinical manifestations and the possible cause.

REPORT OF CASES

Miss M. B., a housemaid, aged 25, entered the University Hospital for the third time Nov. 30, 1936, with symptoms of a severe crisis of hemolytic jaundice. On the two previous hospital admissions, four years before, she had been in similar crises with a red blood cell count of about one million. Symptoms of increasing weakness, yellowish pallor and bouts of diarrhea had been present for two months.

On physical examination the patient was extremely pale and moderately jaundiced. The temperature was 101.6 F., the pulse rate 120, the blood pressure 108 systolic and 62 diastolic. There were no purpuric manifestations on the skin, and the sticking test was negative. There was no glossitis or papillary atrophy of the tongue. Generalized lymphadenopathy was absent. There were no pulmonary abnormalities, and except for a soft systolic murmur at the apex, hemic in origin, the

heart was normal. The liver edge was just palpable; the spleen was enlarged 4 cm. below the left costal margin. The neurologic examination was negative.

At the time of admission the hemoglobin content was 20 per cent (2.9 Gm.), the erythrocyte count 990,000 and the leukocyte count 4,000. Except for a shift to the left of the polymorphonuclear series, the differential count was normal. A study of the blood smear showed extreme variation in the size and shape of the red cells with numerous polychromatophilic cells, Cabot rings and Howell-Jolly bodies. The mean corpuscular volume of the erythrocytes was 103 cubic microns; the mean corpuscular hemoglobin content was 36 micrograms. The bleeding, clotting and clot retraction times were normal, the platelets slightly reduced. The reticulocytes were 5.5 per cent. The fragility test of the red cells showed beginning hemolysis at 0.46 per cent and complete hemolysis at 0.28 per cent. The icterus index was 27 units, the van den Bergh reaction indirect, quantitatively 2 mg. per liter. There was complete absence of free hydrochloric acid in the gastric contents, and examination of the stool was negative for blood. The urine was normal and the Wassermann reaction of the blood was negative. A biopsy of the bone marrow showed marked hyperplasia of the erythropoietic tissue.

The patient was critically ill. Emergency splenectomy was considered, but transfusions were elected in view of the extremely low blood counts and the poor operative risk. A transfusion of 450 cc. of whole blood by the indirect citrate method was given on each of two successive days. Though there was no immediate febrile reaction following transfusion, a few hours after the second one the patient complained of severe abdominal pain. The jaundice became more intense and the spleen became tender and increased in size. The temperature gradually rose to 105.4 F. During the next twenty-four hours the erythrocyte count dropped from 1,700,000 to 1,360,000 and the hemoglobin content from 36 per cent to 25 per cent (chart 1). The donor-

Chart 1.—Course in case 1.

recipient bloods were rematched and found to be compatible. The patient was watched carefully for signs of renal damage, but no anuria, hematuria or hemoglobinuria developed. Four days later splenectomy was performed under gas-ether anesthesia with prompt improvement in the blood and progressive decrease of the jaundice. Two months later the gallbladder was removed because of cholelithiasis. The patient was discharged from the hospital in a greatly improved state, both clinically and hematologically.

E. M., a white man aged 61, a laborer, entered the University Hospital for the first time May 7, 1937, complaining of intermittent weakness since 1932. For several months during each of the past five years he had been forced to stop work because of fatigue. About eight months before admission to the hospital

a diagnosis of pernicious anemia had been made elsewhere and oral and intramuscular liver extract had been administered. Though considerable improvement was first noted, a severe relapse soon occurred while he was still under intensive liver therapy. Symptoms of marked weakness, dyspnea and palpitation on exertion, dizziness and a lemon-yellow pallor had all been slowly progressive in spite of all types of antianemic therapy. He stated that he had had no symptoms of sore tongue, paresthesia or gastrointestinal complaint. The past and family histories were noncontributory except to note that a brother had been jaundiced for some time at the age of 20 years.

On physical examination the patient appeared well nourished. The temperature and pulse and respiration rates were normal. There was a definite icteric tinge of the skin and sclera, and the mucous membranes were pale. The eyes, ears, nose and throat were not abnormal, except for the retinal examination, made by Dr. Harold Gifford, which showed many scattered hemorrhages. There was no evidence of redness of the tongue or papillary atrophy. There were a few pea-sized cervical lymph nodes but lymphadenopathy was not generalized. The lungs were clear and the heart was not remarkable in rhythm or sounds. There was a two plus sclerosis of the radial vessels, and the blood pressure was 112 systolic and 72 diastolic. The spleen was enlarged to 7.5 cm. below the left costal margin and

Chart 2.—Course in case 2.

was smooth and firm. There were no areas of abdominal tenderness and no abnormal masses palpable. The neurologic examination was negative.

A blood count disclosed a hemoglobin content of 57 per cent (8.2 Gm.), erythrocytes 2,860,000, and leukocytes 3,200 with 30 per cent of the segmented polymorphonuclear type, 31 per cent staff form, 26 per cent lymphocytes, 6 per cent monocytes and 1 per cent eosinophils. The smear of the red blood cells showed marked achromia with anisocytosis and poikilocytosis with a shift toward the macrocytic side, polychromatophilia and nucleated red cells (5 per hundred white cells). No spherocytes were noted. The mean corpuscular volume was 124 cubic microns, the mean corpuscular hemoglobin 32.4 micromicrograms, and the mean corpuscular hemoglobin concentration 28 per cent. The reticulocytes varied from 10.3 per cent to 14.3 per cent. The fragility of the red cells to hypotonic salt solution showed beginning hemolysis at 0.42 per cent and complete hemolysis at 0.32 per cent. The platelets numbered 230,000. The bleeding and clotting times were normal with firm and rapid retraction of the clot. The urinalysis was negative as well as the Wassermann reaction of the blood. The gastric content showed 13 degrees free acid and 27 degrees total acid; examination of the stool was negative for blood. The basal metabolic rate was minus 8 per cent. The blood non-protein nitrogen was 35 mg. per hundred cubic centimeters. The van den Bergh test showed a direct, delayed, slight positive reaction, quantitative 17 mg. per liter. The bromsulphalein liver function test showed 50 per cent retention in five minutes and 10 per cent in thirty minutes. A biopsy of the bone marrow taken from the sternum revealed marked hyperplasia of the erythropoietic tissue.

Splenectomy was advised but the patient refused, and he was dismissed from the hospital with instructions to take weekly intramuscular liver extract and daily doses of reduced iron.

The patient returned to the hospital October 6 with a history of feeling moderately well until six weeks before admission, at which time he first noted vague pain in the upper part of the abdomen associated with frequent attacks of vomiting, increased pallor, deeper jaundice and progressive weakness. The stools were not clay colored and the pain was not colicky at any time. He requested splenectomy at this time.

The physical examination was essentially the same as on his previous admission. The jaundice was definitely more marked and the spleen slightly larger, extending 9 cm. below the left costal margin.

The blood count revealed a hemoglobin content of 25 per cent (4.2 Gm.), erythrocytes 1,000,000, and leukocytes 1,400 with the same differential formula. The fragility of the red cells remained normal, but the reticulocytes had increased to 37.5 per cent and the quantitative van den Bergh reaction was up to 68 mg. per liter. The icterus index was 35 units. The remaining blood studies were essentially the same as on his previous examination. Roentgenograms of the gallbladder failed to show any concentration of the dye, and no opaque calculi were discerned. A study of the gastrointestinal tract showed no abnormality.

In an attempt to build up the patient's general physical condition before operation, intravenous dextrose was administered frequently. In addition, transfusions of 500 cc. of whole blood, by the indirect citrate method, were given on two successive days. The hemoglobin increased to 34 per cent and the red cells to 1,250,000 with 2,600 white cells. Unavoidable circumstances prevented operation being performed at this time. The second day after the second transfusion the patient complained of a recurrence of the vague abdominal pain, which rapidly increased in severity. The jaundice became deeper, the spleen tender to palpation. What first appeared to be a biliary attack was really an acute hemolytic crisis in which the blood slowly decreased to a level of 20 per cent hemoglobin, 980,000 red cells and 2,250 white cells (chart 2). The reticulocytes were 39 per cent; the icterus index increased to 50 units. The stool was highly colored at all times and the van den Bergh reaction remained indirectly positive. Transfusions were resorted to again and two injections of 500 cc. were given on alternate days with no apparent reaction. Though the general condition improved somewhat, the blood count decreased to 16 per cent hemoglobin, the erythrocyte count to 510,000 and the leukocyte count to 2,000, so that emergency splenectomy was performed October 27. The subsequent postoperative course with complications of thrombosis of the splenic and hepatic veins and death has been the subject of another paper.²

COMMENT

When one considers the hundreds of patients with hemolytic jaundice and the number who have been subjected to transfusion either during the bouts of severe anemia accompanying a hemoclastic crisis or in the preparation for splenectomy, the incidence of unfavorable reactions must not be very great. Transfusions as a temporary measure in the acute episodes of destruction of the blood and as a routine preoperative procedure have long been advocated by many authorities.³ Certainly transfusion is of distinct value in patients jaundiced as a result of biliary and hepatic disease.⁴ In addition, transfusion is strongly recommended for the

acute hemolytic anemia of Lederer,⁵ although a fatal reaction has recently been reported.⁶

Lord Dawson⁷ in 1931 was the first to mention the dangerous consequences of transfusion in hemolytic jaundice. In two typical cases in which preparations were made for splenectomy, and after every care in blood typing, transfusion resulted in death. A woman aged 65 with a red blood cell count of 3,050,000 received one transfusion followed by gradually increasing jaundice and death. The second patient, a woman aged 44, received three transfusions over a period of sixteen days, each followed by pyrexia (up to 104 F.), vomiting, diarrhea and deepening jaundice. Toward the end of the course there was increased anuria, which Dawson concluded was due to the blocking of kidney tubules by masses of acid hematin pigment, as shown by Baker and Dodds.⁸ If transfusion is to be given to these patients, Dawson recommends the administration of an initial, small pilot dose of blood before the usual therapeutic amount is given. Wise⁹ in 1933 warned of reactions following transfusion but cited no personal experience. Hartfall and Stewart¹⁰ also in 1933 reported that a woman, aged 52, with typical familial hemolytic anemia and an erythrocyte count of 2,770,000, in preparation for splenectomy, received 500 cc. of type IV blood, following which jaundice increased markedly, with death occurring within twenty-four hours. The postmortem examination showed nothing of note except a massive heterotopia of bone marrow occurring in the thorax. Doan and his associates¹¹ in 1934 again warned that, the more severe the anemia in hemolytic jaundice, the greater the danger of transfusion. They concluded that transfusion was contraindicated as well as unnecessary. Lawrence¹² in 1937 cited the case of a woman aged 50 who before splenectomy reacted moderately after each of three transfusions. Except for a rise in temperature, Lawrence did not give the details of the reaction.

In both of our cases two transfusions were given on two successive days. Both patients were in a state of acute hemoclastic crisis, with the number of erythrocytes about one million, and both were being prepared for emergency splenectomy. Within a few hours after the second transfusion the patients complained of severe abdominal pain and backache. In case 2 the pain simulated biliary colic. Accompanying the abdominal pain there was an increase in the size and tenderness of the spleen, fever and intensification of the jaundice. In each instance the number of erythrocytes decreased to less than one million. The acute symptoms gradually subsided over a period of forty-eight hours, during which time there was no decrease in the amount of urinary output, hematuria or hemoglobinuria. Though both cases were complicated by the presence of biliary lithiasis, so common in hemolytic jaundice,¹ throughout

the attack the stools continued to show bile and the van den Berg reaction, though quantitatively increasing, remained indirectly positive. In each instance following the reaction the donor's blood was rechecked and found compatible with that of the recipient. In fact, in case 1 the same two donors were used again in transfusions following a later cholecystectomy without the appearance of the previous phenomena.

It is impossible as yet to determine definitely the underlying mechanism of these reactions. It may possibly be one factor or a combination of several factors. Doan and his associates¹¹ are of the opinion that the addition of transfused red cells from without only furnishes more material for hemolysis with consequent further pigmentary and toxic embarrassment of the liver and kidneys. On the other hand, these patients who require transfusion are usually in a severe hemolytic crisis, the cause of which is unknown. With their hemopoietic equilibrium already disturbed by the active hemolytic process, the destructive function of the spleen is further intensified by the procedure of transfusion. Apparently the erythropoietic equilibrium of construction-destruction is of such a delicate nature in hemolytic jaundice that the onset of crises may be initiated by dietary indiscretion, constipation, emotional disturbances, chilling, overexertion, acute infections, menstruation, pregnancy, high altitudes and surgical procedures. Finally, the reactions may be merely a part of that group of unexplained delayed post-transfusion reactions that Bordley¹³ in 1931 and Goldring and Graef¹⁴ in 1936 have so aptly summarized as occurring in any number of unrelated conditions. Their group of cases, however, differed somewhat in that they were characterized by the delayed onset of symptoms from one to two weeks after the transfusion and consisted of conditions ranging from drowsiness to coma and convulsions, accompanying marked renal insufficiency, and frequently led to death. At autopsy the kidneys were swollen and tubular epithelial cells contained droplets of peculiar pigmented material and showed advanced degenerative changes. In this group of delayed reactions jaundice was present in only a third of the cases and of mild grade, and there was no tendency for the hemoglobin and red blood corpuscles to decline such as was observed in our cases.

With this complication in mind, the problem naturally arises as to its prevention. A therapeutic lead that might prove of value comes from Witts,¹⁵ who except in emergencies does not permit transfusions to be given until alkalis have been administered in sufficient dosage to render the urine alkaline. This dictum is substantiated by the recent experimental work of DeGowin and his co-workers,¹⁶ who found that when the urine was alkaline the intravenous injection of a large amount of dog hemoglobin into dogs seemed to be innocuous. However, when the urine was acid, transfusion of hemoglobin sooner or later produced renal insufficiency from obstruction of the tubular lumens with masses of pigment derived from hemoglobin. Since transfusion may at times cause the appearance of more alarming symptoms, and even death in an already

critically ill patient with hemolytic jaundice, and since the usual antianemic drugs of iron and liver extract are of little or no avail,¹⁷ it seems that one is left with little to combat the episodes of acute destruction of the blood. Attention is called to the recent observations of Doan¹⁸ and others¹⁹ as to the value of splenectomy in the patient with severe anemia. Suffice it to say, we have fully corroborated their work and conclusions, the details of which will be published in the near future. From our experience, we conclude that transfusion is dangerous in the presence of severe crises; it is contraindicated preoperatively and it is rarely necessary postoperatively.

CONCLUSIONS

1. In two cases of severe crises in hemolytic jaundice, transfusions caused unfavorable and dangerous reactions.

2. Caution must be used in the administration of transfusions to such patients.

MULTIPLE PRIMARY MALIGNANT TUMORS

J. S. EISENSTAEDT, M.D.

CHICAGO

The coexistence of more than one malignant tumor in the same individual has been observed and recorded on many occasions, and in recent years renewed efforts have been made to appraise its incidence by a careful examination of the material provided by large hospitals. According to Hanlon,¹ up to 1931 only in seven instances have large series of postmortem examinations been studied for the purpose of determining the frequency, distribution and other factors relating to the occurrence of multiple primary malignant tumors. Before 1931 von Hauseman,² Puhr,³ Gade,⁴ Feilchenfeld,⁵ Redlich,⁶ Reichelman⁷ and Harbitz⁸ made contributions to the subject. Since then Hanlon, Warren and Gates,⁹ Schreiner and Wehr,¹⁰ Bugher¹¹ and, most recently Burke¹² have published excellent reports.

Hanlon was able to find only twenty-five reports in which three or more carcinomas were present in one individual. However, with more careful and complete postmortem examinations, especially in this country, more cases are steadily being reported. It is notable, as will be seen in the accompanying table, that in centers reporting the largest number of cases special attention has been paid to postmortem analyses of

tumors and specialized facilities for therapy have attracted large numbers of patients affected with malignant disease.

The criteria necessary to make a diagnosis of multiple primary malignant tumors were first formulated seventy-seven years ago by Billroth¹³ as follows:

1. Each tumor must have an independent histologic appearance.
2. The tumors must arise in different situations.
3. Each tumor must produce its own metastases.

Since then most authors have objected to the third requirement of Billroth, which has been considered as obviously too strict, and the following criteria observed by Warren and Gates have been accepted by most authors:

1. Each tumor must present a different picture of malignancy.
2. Each tumor must be distinct.
3. The probability of one metastasizing from the other must be excluded.

As the knowledge of carcinoma has increased and confidence in our ability to distinguish between primary tumors and metastases has been gained, there has been a liberalization in the requirements for making a diagnosis. In establishing the diagnosis of multiple primary carcinoma the greatest reliance has been placed on the distinct variation in the microscopic appearance of the several tumors.

Hanlon noted an extensive lapse of time between the appearance of the different new growths. He also noted from his examination of all available reports that the age incidence in this group of patients was of great interest. The average age of the patients who had three or more carcinomas was 63.6 years, while the average age of those who had two carcinomas was 58.8 years. These patients were several years older than those dying with a single malignant new growth. This statement is not in agreement with that of Warren and Gates, who concluded that multiple primary carcinoma occurs at approximately the same age as does a single lesion. However, other observers agree with Hanlon; they state that in most instances an interval of from five to twenty-three years elapsed between the development of the several tumors. Such is the experience of Hartman, who insists that he has cured by surgery several patients with primary neoplasm developing subsequent to the eradication of the first tumor in a separate and distant organ.

The distribution among the various organs corresponds closely with the percentage distribution of malignant new growth when it occurs singly.

It has been observed that the combination of malignant tumors in the genito-urinary and gastrointestinal tracts is relatively more frequent than other combinations. Carcinoma of the kidney of all types and carcinoma in various locations in the gastrointestinal tract have been recorded by Hanlon, Pietrusky,¹⁴ Orr,¹⁵ Nobiling,¹⁶ Junghanns,¹⁷ Tanberg¹⁸ and others. Most of the kidney tumors recorded in the literature, however, were small and went unrecognized but possessed definite microscopic stigmas of a malignant condition. Most were slow growing and represented a low degree of malignancy. In Hanlon's group,

studied at the Mayo Clinic, the distribution of multiple primary cancers was as follows: kidney nine times, colon nine, thyroid four, stomach three, ovary two, and in the following locations one each: parathyroid, mouth, prostate, anal margin, uterus, breast, larynx, ileum and nose.

Fig. 1.—Adenocarcinoma of right kidney removed in 1915. Note papillary and tubular arrangement of cells.

Concerning the appearance of multiple primary malignant new growths, there are at least three different and divergent opinions expressed by various authors.

Ewing¹⁰ is of the opinion that their occurrence can be explained on the grounds of mere coincidence. Orr concurs in this opinion, while Hanlon concludes that multiple primary cancers represent incidental occurrences rather than a definite response to any law of neoplastic formation. Murray²⁰ and others believe that the presence of one malignant new growth has an inhibitory influence on the development of a second. On the other hand, Warren and Gates express the opinion that multiple primary malignancies may be explained by a predisposition or susceptibility to carcinoma in

certain persons or to the action of some factor favoring the development of a malignant condition but conclude that the nature of this predisposition is as yet unknown. This point of view coincides with that of Hartmann²¹ and others. Hurt and Broders²² concluded that the incidence of multiple malignant growths is greater than recorded and noted a positive hereditary factor in 28.6 per cent. Bugher, using the United States mortality statistics, computed the expected occurrence of multiple primary malignant growths on the basis of chance and found it to be exceeded by the actual occurrence; he says that the authors who have reported the largest series of multiple cancers have felt that these tumors occur more frequently than chance alone can explain and that their actual frequency exceeds their reported incidence.

The case here reported is of interest, I believe, not only because the patient had three separate and distinct primary cancers diagnosed clinically but also because he lived twenty-one years after nephrectomy for cancer of the kidney. During this long period, although this is not a record for this type of lesion, he showed no evidence of recurrence and at autopsy no vestige of this tumor was discovered after minute examination of all the tissues. A condensed history is as follows:

REPORT OF CASE

A man, aged 49, entered the Michael Reese Hospital in March 1915. He stated that four years before he began to pass blood in the urine. The hematuria was not accompanied by pain before, during or after micturition. There was no urinary frequency. Blood reappeared in the urine at intervals of from six to eight weeks and lasted each time from one to three weeks. About two years before his entrance to the hospital, marked gross hemorrhage appeared in the urine and at this time he first noted slight pain in the penis during the act of urination, and he began to void more frequently. During the past two years (1913-1915) besides the appearance of hematuria he suffered attacks of pain in the right lumbar region. These

Fig. 2.—Primary carcinoma of prostate. Note large oval and polygonal cells with vesicular nuclei showing atypical mitotic figures.

were of short duration, lasting but a few minutes to twenty or thirty minutes—never longer—and would recur every four to six weeks. Blood was always seen in the urine during or after an attack. During the six months previous to admission to the hospital, the hematuria had become much worse and was more frequent.

22. Hurt, H. H., and Broders, A. C.: J. Lab. & Clin. Med. 18:765 (May) 1933.

The past history was negative except for stomach trouble seventeen years before. In the family history it was noted that his wife had had one miscarriage and that they had one living child, 14 months of age. He had had gonorrhea several times; the history of syphilis was doubtful.

Physical examination was negative except for rigidity over the right lumbar region.

Fig. 3.—Metastasis to lungs. Note characteristic large vesicular nuclei with prominent nucleoli similar to those seen in section from prostate.

Cystoscopy was negative except for slight encroachment of the prostate on the internal urethral orifice.

X-ray examination revealed a calculus in the right kidney, which was probably in a calix, and a second stone at the ureteropelvic junction.

Laboratory examinations at that time gave the following results: Repeated urinalyses showed specific gravity from 1.020 to 1.028. The reaction was consistently acid. There was constantly a 1 plus albumin reaction. Neither sugar nor acetone was found at any time. Microscopic examinations at no time showed casts, but white blood cells were always present in from five to fifteen cells per high power field to many, and the red blood cells varied from none to an occasional one.

Right nephrectomy was done in March 1915 by Dr. Kolischer. When he exposed the kidney a tumor mass was seen involving the middle third. The gross description of the kidney removed was as follows:

The kidney was slightly increased in size and measured 12 by 6 by 4 cm. It showed a cortical nodule occupying the whole of the middle third of the kidney, involving the whole thickness of the cortex and invading the pelvis. The tumor was spherical and measured 4 cm. in diameter. It was nodular and of firmer consistency than the kidney. The color was variegated from a yellowish to a bluish tinge. No secondary nodules were found. There was a small irregular stone lodged in one of the calices.

The patient again entered the hospital in 1926 for a spinal puncture, which confirmed the clinical diagnosis of tabes dorsalis, after which he remained under treatment for this condition for one year.

Ten years later, in July 1936, at the age of 70, he was sent to the hospital for urologic study, from the outpatient department. At this time he complained of frequency of urination, nocturia and dribbling, all of about three years' duration.

The history taken at this time stated that these symptoms had been of a mild nature for the preceding two or three years. He also complained of pains beginning in the lumbar region and radiating down both legs. These pains had been present for about one year. They were quite severe three weeks before admission to the hospital but were relieved by rest in bed. On entrance the temperature was 98.2 F., pulse 78 and respiratory rate 18. The blood pressure was 115 systolic, 70 diastolic. The essential physical observations were as follows: The pupils were normal (?). The cervical lymph nodes were enlarged. The chest was emphysematous and the heart tones were distant. The knee and ankle jerks were bilaterally absent.

There was an old scar on the penis. Rectal examination showed an enlarged prostate of markedly increased consistency. The outline was irregular and the surface nodular. A diagnosis of carcinoma of the prostate was made. Tabes dorsalis also was diagnosed. Metastases to the bones from cancer of the prostate were suspected, but x-ray examination failed to verify this assumption.

Other laboratory examinations were as follows: Further roentgenologic examination showed a point of obstruction in the hepatic flexure of the colon, causing delay in the passage of the barium sulfate meal. An opaque enema did not pass beyond the sigmoid. These observations were interpreted as probable carcinoma of the colon.

The Wassermann reaction of the blood was negative, while the spinal fluid yielded a positive Wassermann reaction.

The blood count showed 4,150,000 red blood cells, 75 per cent hemoglobin and 9,700 white blood cells.

Examination of the urine was negative for all pathologic elements.

Examination of the stools showed a 3 plus test for occult blood.

No urologic intervention was deemed necessary on account of the relative mildness of the urinary symptoms and because of the suspected carcinoma of the colon. The patient was therefore transferred to the medical department, where he died six weeks after admission to the hospital.

A condensed report of the autopsy protocol enumerating only the essential observations is as follows:

Enlarged masses of lymph nodes were found along the aorta, as well as marked involvement of the tracheobronchial, retroperitoneal and presacral chains. On section the nodes were a grayish white and of firm consistency.

Both lungs showed grayish white membrane-like, slightly elevated areas on the pleural surfaces.

In the proximal sigmoid was a firm, annular lesion with rolled borders which projected into the lumen of the bowel. It measured 3 cm. in diameter. The mucosa was ulcerated and replaced by a fungating mass.

The prostate was moderately enlarged and semifirm to firm in consistency. On section its normal architecture was obscured by multiple grayish white plaques with irregular outlines. There was no obvious obstruction of the prostatic urethra.

Fig. 4.—Primary adenocarcinoma of sigmoid colon. Note infiltration of muscularis and submucosa by anaplastic cells, arranged in acinous and tubular conformation.

The posterior columns of the cord were small and atrophic, and in the middorsal region were areas of softening. There was some atrophy of the left cerebral cortex.

The microscopic report of the three tumors follows:

Right Kidney (removed in 1915).—The tumor varied in characteristics from areas with solidly packed cells to areas with reproduction of glandular lumens and proliferation of cells in papilliferous arrangement. The cells varied markedly in size and shape. In the more papilliferous portions there were large oval

cells with abundant eosinophilic cytoplasm and round, moderately chromatic nuclei. In these areas as well as elsewhere there were smaller cells with less cytoplasm and more hyperchromatic nuclei. Few mitotic figures were evident. Fibrous connective tissue was abundant and contained a marked lymphocytic infiltration. In one area several hyalinized and partially hyalinized glomeruli were present.

Prostate.—Within the prostatic parenchyma, which was involved by diffuse hyperplasia of the glandular structures, were several areas in which the epithelium of the acini completely filled their lumens. The cells were large, from oval to polygonal in shape, and contained a faint eosinophilic cytoplasm. Cell borders were distinct. The nuclei were large, oval to round in outline, pale and containing faint chromatin granules with prominent nucleoli. Atypical mitotic figures were frequently present. Elsewhere definite structure was absent and the connective tissue and smooth muscle were widely infiltrated by rounded masses, strands and individual cells of similar type interspersed, however, with many smaller cells containing hyperchromatic nuclei. In several smaller vessels, masses of both types of cells plugged the lumens. They were also characteristically arranged about some of the nerve fibers.

Lung Metastases.—Sections from the lungs revealed solid masses of cells similar to those in the prostate invading perivascular connective tissue and extending along the septal walls. The characteristic large vesicular nuclei with prominent nucleoli were noteworthy.

Sigmoid.—Sections from the tumor in the sigmoid colon revealed degenerative and necrotic changes in the mucosa with loss of cell outlines, pyknosis and fragmentation of nuclei, and also an infiltration with lymphocytes. The submucosa and muscularis, the latter much thickened, were widely infiltrated by irregular acinous and tubular structures lined by one or two layers of extremely anaplastic cells. A basement membrane was not present. The cells varied greatly in size and ranged in shape from spindle to oval to columnar. Their nuclei varied extremely from hyperchromatic spindle-shaped types to large pale oval types with small chromatin granules and occasional large nucleoli. Atypical mitotic figures were present in moderate number. In many of the glandular lumens a pale mucoid material was present.

The pathologic diagnosis after autopsy was (1) absent right kidney; (2) primary carcinoma of the prostate with metastases to the lungs, retroperitoneal, presacral and tracheobronchial lymph nodes; (3) primary adenocarcinoma of the sigmoid colon with stenosis of its lumen; (4) multiple adenomas of the left kidney; (5) compensatory hypertrophy of the left kidney; (6) generalized arteriosclerosis and coronary sclerosis; (7) healed myocardial infarct, and (8) fibrosis of the myocardium.

COMMENT

A man who died in 1936 had been operated on twenty-one years before for adenocarcinoma of the kidney. He later was affected with two other primary cancers in distinct and separate organs, one of which, that of the prostate, produced metastases to the lungs and lymph nodes. All three cancers were diagnosed clinically.

It is my belief, after a rather complete survey of the literature, that:

1. Multiple primary cancers are more frequent than are reported.
2. They occur more frequently than chance alone would explain.

3. The percentage of multiple primary malignant tumors to be reported in the future will be higher than that recorded in the past, because

- (a) More people are reaching advanced years, a period in which the incidence of cancer is generally high.

- (b) Since the inauguration of cancer clinics and commissions throughout the world, cancer patients have been more concentrated and more thoroughly studied.

- (c) Better results are being obtained in the treatment of cancer than heretofore.

- (d) As a result of longer survival after treatment for a single primary tumor, time is afforded for the development of subsequent primary cancers.

- (e) Autopsies are more widely done and with greater thoroughness than in the past.

4. Some factor, as yet unknown, possibly hereditary or hormonal in nature, plays an important part in susceptibility to malignant disease and the varied responses to environment in different individuals depends on this unknown element.

25 East Washington Street.

THROMBOSIS OF THE AXILLARY VEIN

REPORT OF FIVE CASES WITH COMMENTS ON ETIOLOGY, PATHOLOGY AND DIAGNOSIS

THEODORE KAPLAN, M.D.

Clinical Assistant Visiting Physician, Gouverneur and Bellevue Hospitals;
Physician, Vascular Clinic, St. John's Riverside Hospital, Yonkers

NEW YORK

Thrombosis of veins is common in the pelvic region and in the lower extremities. It may follow abdominal operations or develop during the puerperium. Thrombus formation in the veins of the upper extremities, secondary to such conditions, is not common, and thrombosis of the axillary vein caused by effort is comparatively rare.

As a clinical entity the condition was first described by Von Schrötter in 1884. Cadenat¹ in 1920 reviewed twenty-four cases from the literature. Paggi² in 1933 collected reports of seventy-four cases from medical writings. Matas³ in 1934 reported one case and reviewed the literature of approximately 100 cases. Since then about twenty additional cases have been described by various observers, but great numbers have not been observed by any one person.

A review of the cases by the various authors showed that the patients were young, in good health and engaged in work. Although males were affected to a greater degree, cases in females were reported by Rosenthal,⁴ Cadenat,¹ Winterstein,⁵ Finkelstein⁶ and Clute.⁷ The right arm was affected more often than the left, and those in whom the left arm was involved were either left handed or threw an unusual strain on the left hand. The condition followed an unusual or sudden effort contracted while engaged in heavy work or developed after a casual strain such as is associated with checking and restraining a horse.⁸ It also followed strains that resulted from causes such as swinging at a golf ball, pitching a baseball or exercising in a gymnasium.⁹ Cases have also been reported in which

the thrombus developed spontaneously without any accidental strain.¹⁰

I am herewith presenting five cases of thrombosis of the axillary vein in males. At the time this process developed the patients were in good health and showed no pathologic defects to account for such a condition.

Fig. 1 (case 1).—Comparative size of the arms, the right being larger than the left.

REPORT OF CASES

CASE 1.¹¹—J. C., a man, aged 24, admitted to the clinic July 1, 1936, complained of enlargement and hardness of the right upper extremity and prominence of the veins of the right arm as compared with the left. For the previous year and a half he had been employed as a clothes presser, at which occupation he used his right arm constantly. The past and family history were entirely negative. Three months prior to his coming to the clinic, he suffered from a cellulitis of the right leg. This was treated by rest and by wet dressings and subsided without any operative intervention. One month prior to his appearance at the clinic his attention was called to the fact that his right hand was larger than the left and that the fingers of the right hand were darker than those of the left. The right upper extremity, as far as he could remember, had never been swollen and there had been no impairment of function at any time.

The patient was robust and well nourished; he weighed 147 pounds (66.7 Kg.) and was 65 inches (165 cm.) tall. The general physical examination was entirely negative except for the right upper extremity.

The right upper extremity from the shoulder girdle to the fingertips was larger than the left. The skin had a slight tinge of rubor. Fulness over the anterior wall of the chest below the clavicle and prominence of the veins over the internal aspect

of the arm and the axilla and the anterior aspect of the chest were noted. The veins collapsed slowly on elevation. There was no clubbing of the fingers; no cord or lymph glands were palpated in the axilla. The enlargement was due to a brawny induration. Motion in the joints was unrestricted and sensations were unimpaired. Pulsations in the brachial, radial and ulnar arteries were equal in rate and rhythm as compared with the left. The hand grips were equal in force. The pulses of the lower extremities were all open. The measurements of both upper extremities are given in table 1.

TABLE 1.—Measurements of Both Arms (Case 1)

	Right	Left
At junction of humerus and shoulder.....	39.6 cm.	33 cm.
Midhumeral	30.5 cm.	27 cm.
Elbow	28.5 cm.	26.2 cm.
Midforearm	27.5 cm.	24.6 cm.
Wrist	18.5 cm.	16.5 cm.
Hand	22.25 cm.	20.5 cm.
Temperatures at different levels measured with an electric potentiometer were equal		
Midhumeral	31.8 C.	31.5 C.
Midforearm	32.6 C.	32.5 C.
The blood pressure on the affected side was less than on the other side		
	90/50	95/60
The oscillometric index on the right side was less than that on the left		
Midhumeral	10	11 plus
Midradial	5	6
The venous pressure was increased on the right side		
Cephalic vein	2.8 mm.	118 mm.
Basilic vein	290 mm.	100 mm.
The blood count and urine were normal and the Wassermann reaction of the blood was negative		

Radiographic examination of the chest, cervical spine and right shoulder failed to reveal any tumor masses, presence of the cervical rib or changes in the joints.

Fig. 2 (case 1).—Visualization of upper extremities by means of infra-red rays. The veins of the right arm and of the right side of the chest are more numerous and prominent.

Radiographic examination of the right upper extremity following the injection of 10 cc. of thorium dioxide sol into the median cephalic vein visualized the vein up to the junction of the upper and middle third of the humerus, at which point numerous venous collaterals were seen on the external aspect of the humerus. Collaterals were also noted in the shoulder and supraclavicular regions. The cephalic vein failed to empty

10. Pellot: Un cas de thrombose veineuse du membre supérieur droit (phlébite par effort), *Presse méd.* 24: 523 (Nov. 20) 1926. M.: Primary Thrombosis of the Axillary Vein, *Arch. Surg.* 21: 271-289 (Aug.) 1935.
11. Kaplan, Theodore, and Katz, Abraham: Thrombosis of the Axillary Vein, *Am. J. Surg.* 37: 326-333 (Aug. 1) 1937.

directly into the axillary. Two venous segments were also noted in the infraclavicular region, the upper one corresponding to the terminal portion of the cephalic vein at the site where it usually empties into the axillary, and the lower one representing the narrowing of the axillary vein. It received the venous tributary running from the point of the interruption to the cephalic vein across the humerus to be joined by the long thoracic vein that is visualized. Another venous collateral was also seen coming across just at the level of the head of the humerus and emptying into the same segment.

Examination of the right arm immediately after the first plate was taken revealed the dye still present in the vein at the level of the junction of the middle and upper thirds of the humerus, and several venous collaterals were still visualized on the external aspect of the shoulder. The two venous segments previously reported were still visualized, and the collaterals emptying into it were no longer seen.

Examination of the right upper extremity following the injection of 10 cc. of thorium dioxide sol into the median basilic vein showed the basilic vein to be well visualized and

the veins became prominently displayed over the arm and chest, and the right arm became red as compared with the left.

The patient was robust and well nourished; he weighed 170 pounds (77 Kg.) and was 70½ inches (179 cm.) tall. The

Fig. 3 (case 3).—Comparative size of the arms, the left being larger than the right.

istended. The valves were dilated and the vein was tortuous. Examination of the right arm, directly after the previous plate was taken, revealed the dye to be still faintly present at the site of the valves.

Infra-red photography of the right pectoral and upper arm regions visualized more veins as compared with the left.

CASE 2.—D. H., a man, aged 25, employed as a salesman, admitted to the clinic Sept. 11, 1936, complained of a difference in the size of his arms, the right being larger than the left. His previous history, both personal and family, was irrelevant.

In the latter part of May 1935, after pitching a ball, he felt a slight soreness in the muscles of the right arm. He massaged the arm and obtained relief temporarily. The following morning the arm was painful, and toward evening the entire right upper extremity was swollen and blue. There was never any acute pain, although function in the arm was impaired; nor was he confined to bed because of a rise in temperature. He kept the arm in a sling and applied wet dressings, and the edema subsided. However, after the slightest exertion, such as carrying a 5 pound weight, the arm from the wrist to the shoulder would become swollen, tired and heavy. When he awoke in the morning the arm always seemed normal in size and color. As time went on, however,

Fig. 4 (case 3).—Film taken immediately after the injection of 10 cc. of thorium dioxide sol into the cephalic vein. The cephalic vein is visualized up to the level of the surgical neck of the humerus, at which point it terminates into a Y bifurcation. The lateral thoracic vein is filled, as well as the jugular in the neck above the clavicle, with a back-flow downward anteriorly to the level of the second rib. The veins in the neck are seen to make a loop terminating below the clavicle.

entire physical examination was negative save for the upper right extremity. The latter was larger than the left with fulness over the right upper wall of the chest anteriorly.

Fig. 5 (case 3).—Numerous superficial veins over the left arm, shoulder region and chest visualized by infra-red rays.

Numerous veins were seen over the forearm and arm, in the axilla and anteriorly over the chest. The veins collapsed slowly on elevation and no clubbing of the fingers was noted. A cord present in the axilla was not tender. No lymph glands were palpable in the cervical and axillary regions. The pulses were

open and were equal in rate and rhythm as compared with the left. Motion was unrestricted, sensations were unimpaired and the reflexes were normal. The measurements of both upper extremities are shown in table 2.

Injection of the right median basilic vein with 10 cc. of dye revealed the basilic vein to be dilated and the valves prominent.

Fig. 6 (case 4).—Increase in the number of superficial veins of both arms shown by infra-red rays.

No collaterals were visualized. A film taken immediately after the first plate showed the dye to be still present at the site of the valves.

TABLE 2.—Measurements of Both Arms (Case 2)

	Right	Left
At junction of humerus and shoulder.....	33.75 cm.	30 cm.
Midhumeral	30 cm.	27.5 cm.
Elbow	27.5 cm.	26.25 cm.
Midforearm	27.5 cm.	25 cm.
Wrist	17.5 cm.	17 cm.
Hand	23.75 cm.	22.5 cm.
The temperature of the right upper extremity at different levels was definitely less than that of the left		
Midhumeral	31.8 C.	32.4 C.
Elbow	31.8 C.	33.2 C.
Midforearm	31.0 C.	33.2 C.
Wrist	32.0 C.	32.6 C.
The blood pressure of the right arm was greater than that of the left		
	130/72	120/70
The oscillometric index on the right side was greater than on the left		
Midhumeral	11 plus	10 plus
Midradial	5½	4 plus
The venous pressure was increased in the right arm		
Basilic vein	200 mm.	100 mm.
The circulation time with calcium gluconate in the affected side was prolonged		
Basilic vein	27 seconds	14 seconds
The blood count and urine showed no abnormalities and the Wassermann reaction of the blood was negative		

Photographs taken with infra-red technic revealed an increase in the number of veins in the right upper extremity as compared with the left.

CASE 3.—L. K., a man, aged 42, employed as a tailor, admitted to the clinic in February 1937, complained of an enlargement of the left arm of twenty years' duration.

His past and family history was negative. Twenty years before he was admitted he fell in the street and injured his left hand. Four hours later the entire upper extremity became swollen, and he was unable to lift anything. The swelling lasted for two days, during which time he was disabled. Since then he has been working, although his left arm feels weak.

In August 1936, after lifting a weight, his hand became red, painful and swollen and has so continued.

Inspection of both upper extremities revealed the left arm, which had a dusky color, to be larger than the right. The veins were markedly prominent over the left arm, left side of the chest and the left axilla as compared with the right, and collapsed slowly on elevation. A distended vein could be seen running over the neck anteriorly and over the chest. A cord

TABLE 3.—Measurements of Both Arms (Case 3)

	Right	Left
Junction of shoulder and arm.....	29 cm.	33.5 cm.
Midhumeral	28 cm.	33 cm.
Elbow	24.5 cm.	28 cm.
Forearm	26 cm.	28.5 cm.
Hand	21.4 cm.	22.25 cm.
The temperature measured with an electric potentiometer was slightly greater on the right side		
Midhumeral	32.8 C.	32.4 C.
Midforearm	31.8 C.	31.6 C.
Index finger	31.2 C.	30.4 C.
The blood pressure on the affected side was less than on the other		
	136/84	118/80
The oscillometric index on the left side was less than on the right		
Midhumeral	15 plus	11 plus
Wrist	8	5
Circulation time with calcium gluconate was prolonged in the left basilic vein		
Basilic vein	10½ seconds	18½ seconds
The venous pressure was increased on the affected side		
Cephalic vein	110 mm.	180 mm.
The urine and blood count were normal and the Wassermann reaction of the blood was negative		

could be felt in the axilla but it was not tender. The pulses were open and of equal intensity. The hand grip on the left side was weaker than that on the right.

The measurement of the extremities showed the left to be definitely larger than the right (table 3).

Injection of 10 cc. of thorium dioxide sol into the cephalic vein visualized it up to the level of the surgical neck of the

Fig. 7 (case 4).—Film taken immediately after 10 cc. of thorium dioxide sol was injected into the median basilic vein. The vein is dilated with collaterals in the supracondyle region on the internal aspect of the humerus. Numerous collaterals are seen on the external aspect of the arm. Communicating branches between the basilic vein and the collaterals are seen. The valves are markedly dilated. The lateral thoracic vein is partly filled. Veins are visualized in the supraclavicular and cervical regions.

humerus, at which point it terminated with a bifurcation into a Y. The lateral thoracic vein was seen filled, as well as the jugular in the neck above the clavicle, with a backflow downward anteriorly to the level of the second rib. The veins in

the neck are seen to make a loop terminating below the clavicle. The second film, taken about two minutes later, still visualized the lateral thoracic vein.

Infra-red photographs revealed a marked increase in the number and distribution of the veins in the left side as compared with the right.

CASE 4.—H. C., a man, aged 40, an Albanian, reporting to the clinic April 23, 1937, complained of a painful and swollen

Fig. 8 (case 4).—Second film, taken two minutes after figure 7, showing the dye present in the vein. The valves are not as well visualized as in the previous film. The veins in the neck and supraclavicular regions are not seen.

upper extremity. April 21, 1937, at about 8 a. m., he lifted a cake of ice and experienced a slight pain in the arm. At 11 o'clock he noticed that his right hand became stiff, swollen

TABLE 4.—Measurements of Both Arms (Case 4)

	Right	Left
Junction of shoulder and arm.....	34 cm.	32 cm.
Midhumeral	31 cm.	27 cm.
Elbow	27 cm.	24 cm.
Midforearm	50 cm.	27 cm.
Wrist	17.5 cm.	16.5 cm.
Hand	23.5 cm.	22 cm.
The temperature measured with an electric potentiometer was slightly greater on the left side

Ring finger	31.2 C.	32 C.
Little finger	31.2 C.	32 C.
The blood pressure on the affected side was less than on the left side		
	120/70	136/80
The oscillometer readings on the right side was lower than on the left		
Midhumeral	9	11
Wrist	4	4½
The circulation time with calcium gluconate was prolonged		
Basile vein	24 seconds	14 seconds
The venous pressure was markedly increased in the right basile vein		
Basile vein	420 mm.	120 mm.
The blood count and urine were normal and the Wassermann reaction of the blood was negative		

veins collapsed slowly on elevation. No tender cord was felt in the axilla. The fingers were larger than those on the left and were cyanotic. The pulses were open.

The measurements of both upper extremities are given in table 4.

A film taken immediately after the injection of 10 cc. of thorium dioxide sol into the median basilic vein showed the vein to be dilated with collaterals in the supracondylar region on the internal aspect of the humerus. Numerous collaterals were seen on the external aspect of the arm. Communicating branches between the basilic vein and the collaterals were seen. The valves were markedly dilated. The lateral thoracic vein was filled in part. Veins were also seen in the supraclavicular and cervical regions.

A second film taken two minutes after the first visualized the dye in the vein, although the caliber was diminished. Occasional collateral veins were seen on the external aspect, and the veins in the neck were no longer visualized.

A third film taken ten minutes after the injection showed shadows of dye remaining in the basilic vein at the site of the valves.

Infra-red photography showed numerous veins on both upper extremities but more on the right.

CASE 5.^{11a}—J. R., a Negro, aged 37, employed as a garage worker, reporting to my office on May 15, 1937, complained of pain and enlargement of the left arm. On April 13, 1937, he picked up an automobile battery from the floor and, as he did so, felt a sudden pain in the left arm. The pain was so sharp that he had to drop the battery. One-half hour later his arm became swollen and turned blue. He was treated with rest in bed, heat and massage, and the edema subsided. On May 10

Fig. 9 (case 5).—Increased number of veins over the anterior aspect of the chest, arm and forearm visualized by infra-red rays.

he returned to work. The swelling returned, however, and he was forced to discontinue work.

Examination was negative save for the local condition of the left upper extremity. The left arm was larger than the right. The veins were markedly dilated over his arm and side of the chest and did not collapse on elevation. On the left lateral thoracic wall a prominent dilated vein was noted. A hard tender cord was felt in the left axilla, which was continuous

^{11a}. This patient was seen through the courtesy of Dr. Saul S. Samuel of New York.

and cold. He kept the hand over a gas heater to warm it up, but the swelling progressively increased. The pain was constant and dull in character, and he was unable to work.

Examination was negative except for the local condition. The right arm was larger than the left and the skin had a dusky color. The veins stood out prominently over the arm and chest, and venules were noted on the right side of the chest. The

along the course of the basilic vein down to the midforearm, and the entire vein was thrombosed and, because of the thrombosis of the basilic vein, the venous pressure, circulation time and venograms were not taken.

The measurements of both upper extremities are given in table 5.

Infra-red photographs showed numerous veins over the anterior chest, axilla and arm, as compared with the right.

ETIOLOGY

According to Cadenat,¹ Von Schrötter in 1884 described this condition and advanced the theory that, as a result of a sudden stretching and compression of the vein, a localized phlebitis followed, which in turn produced a thrombosis of the vein. Lowenstein¹² in 1924 dissected thirty-seven cadavers and found that with the arm in the abducted position in certain cadavers, the costocoracoid ligament and subclavius muscle indented the axillary vein. When the arm is held in abduction or extension the axillary vein is distended. Distention of the axillary vein with pressure on it by the costocoracoid ligament and subclavius muscle was sufficient to produce thrombosis.

Gould and Patey¹³ confirmed this observation. They injected plaster of paris into the axillary vein of cadavers with the arm in the abducted position and

were subjected to culture. In four of the seven thrombi the cultures were sterile. In the others the cultures yielded bacterial growths, but changes in the vessel wall indicated the presence of a severe inflammatory type of septic phlebitis. Other evidences against infection are, however, the clinical history, the absence of a rise in temperature and the absence of other concomitant signs and symptoms of infection. Matas also quoted Cottalorda, who advanced the theory that the lesion need not necessarily consist of a thrombus formation but that the vein may be held in a spastic state as a result of the irritation of the perisymphatic venous plexus. However, in the majority of cases, extensive thrombus of the vein has been found. The only case substantiating the theory of spasm was that reported by Cottalorda, who, on operation, found no thrombus but the vein in a spastic state.

PROGNOSIS

Prognosis as to life is good. The duration of the disability is variable. Patients may be completely restored in from one to two months and in many cases the convalescence is prolonged because of edema, weakness and stiffness of the arm. Recurrences are occasionally noted following exertion.

TREATMENT

In the acute stage the treatment consists of rest, elevation and hot moist packs locally. If there is residual edema, an elastic bandage may be applied spirally, beginning at the hand and extending upward to the shoulder. Diathermy is of value in reducing the swelling. In obstinate cases, excision of the thrombus or the entire segment of the thrombosed vein has been recommended. However, the advisability of such procedures is questionable, since after removal of the thrombus recurrence is likely, and if the venous segment is resected the chance for canalization of the organized thrombus is lost.

DIAGNOSIS

The diagnosis of primary axillary thrombosis is made on the following symptoms and signs:

1. Swelling of the arm and cyanosis within several hours or days after the accident, injury by strain or, occasionally, without any cause.
2. The absence of a rise in body temperature and absence of signs of local active inflammation.
3. The presence of dilated superficial veins on the affected arm and over the anterior part of the chest and also in the axilla.
4. The delay or absence in the collapse of the superficial veins of the upper extremity when the latter is raised above the heart level.
5. The presence of a cord in the axilla, which need not always be tender.
6. The increase of the venous pressure in the affected extremity.
7. Prolongation of the circulation time in the affected arm.
8. X-ray visualization of new collateral formation, enlargement and dilatation of the veins, evidence of stasis, on injection of radiopaque dyes into the veins of the affected arm, and the failure of the axillary vein to be visualized.
9. The presence of numerous superficial veins on the affected side as shown by photography with the infra-red technic.

224 East Fifteenth Street.

observed, in two cases, deep grooves corresponding in one to the pressure of the subclavius muscle and, in another, a shallow groove corresponding to the position of the costocoracoid ligament. They also demonstrated a competent bicuspid valve at the level of the subclavius muscle which was so placed that pressure of the muscle stretched the wall of the vein in its long axis. They were of the opinion that the subclavius is responsible for trauma to the vein and that, as a result of this trauma, a valve is ruptured. This rupture, according to them, is the fundamental basis for the thrombus.

Veal and McFetridge¹⁰ on the basis of roentgen and autopsy studies reported that the constriction of the vein occurred, not as was previously believed over the first rib beneath the subclavius muscle, but below the head of the humerus and against the subscapularis muscle.

Although these facts may be true in cases in which marked trauma has occurred, it still does not explain the cases in which trauma was slight or those occasional spontaneous cases without any history of injury.

As for infection, Matas reported twenty-seven cases in which the thrombus was removed and seven of them

NICOTINIC ACID IN THE PREVENTION
OF PELLAGRA

A PRELIMINARY NOTE

H. L. SCHMIDT JR., M.D.
AND
V. P. SYDENSTRICKER, M.D.
AUGUSTA, GA.

As a natural sequel to the discovery that nicotinic acid is highly effective in the cure of canine black-tongue¹ and in the rapid relief of part at least of the syndrome of human pellagra,² it was determined to test the potency of this substance as a preventive of relapse in known pellagrins. The present report deals with observations made on a group of such individuals under reasonably adequate control.

METHOD AND MATERIALS

Subjects.—Thirty-three patients were chosen from the files of an outpatient pellagra clinic which is conducted annually from March 1 to December 1 and which has some 350 clients. Only persons known to have had severe pellagra in previous years and showing definite symptoms of relapse on March 9, 1938, were selected for the experiment. Sixteen persons were given nicotinic acid; the remaining seventeen constituted a control group and were given the customary ration of brewers' yeast. No attempt to modify the diet or environment was made in any case, since it seemed obvious that the diet used by these people was productive of pellagra. Two men were chronically alcoholic; all other patients were typical endemic pellagrins. The data regarding age, race, sex, number of previous attacks of pellagra and the severity of presenting symptoms are summarized in tables 1 and 2.

Dosage.—No information was available regarding the amount of nicotinic acid necessary to prevent the recurrence of pellagra. It was decided to try the effect of 100 mg. given twice a week. Dr. Spies³ at the time concurred in the idea that this amount might be effective. The control group was given dried brewers' yeast 90 Gm. daily, the amount employed as a routine for prevention in this clinic.

Control.—All patients were seen on Wednesday of each week by an experienced observer, who noted the progress of all symptoms and signs and dispensed nicotinic acid in capsules containing 100 mg., one to be taken on Thursday and Monday of each week. All observations were made by the same individual. Treatment was begun March 16, 1938, and continued until April 27, 1938, when this experiment was terminated.

Materials Used.—Nicotinic acid was the crystalline preparation of the Eastman Kodak Company; brewers' yeast was Fleischmann's product, furnished by the American Red Cross.

From the University of Georgia School of Medicine and the University Hospital.

Invaluable aid was given by the local chapter of the American Red Cross in the conduct of the Pellagra Clinic and the provision of yeast and a portion of the nicotinic acid used in this study.

RESULTS OF TREATMENT WITH YEAST

The comparison of results in the two groups can best be made by reference to the tables. It is apparent that the majority of patients studied were in age groups in which senile and arteriosclerotic changes may have contributed largely to the occurrence and persistence of mental symptoms. Frank neurologic disturbances were not observed. It is also obvious that the group treated with nicotinic acid was composed of persons who had suffered more frequent attacks of pellagra than most of the controls. Some degree of glossitis persisted in all but one of the patients given yeast but their general improvement was satisfactory, none regressed and all showed marked subjective as well as objective relief with restoration of appetite and gain in strength and weight.

RESULTS OF TREATMENT WITH NICOTINIC ACID

In the group treated with nicotinic acid there were interesting variations. During the first two weeks improvement of glossitis and of appetite were noted in

TABLE 1.—Results of Treatment with Yeast

Number	Initials	Previous Attacks	Age	Race	Sex	Before Treatment					After Treatment

Summary of results obtained in patients treated with 90 Gm. of brewers' yeast daily from March 16 to April 27, 1938. The figures in the columns under the signs and symptoms listed indicate severity: 1, mild; 2, moderate; 3, severe; 4, very severe.

all, the changes in the appearance of their tongues being more striking than in the controls. After this time the progress of different individuals was most irregular. Patient 10 continued to improve; he was a chronic alcoholic addict and was frightened into complete sobriety. Patients 1, 2, 6, 7, 8, 11, 12, 14 and 16 improved in all respects for four weeks and then showed recurrence of glossitis with gradual loss of appetite and strength, so that their condition at the end of the sixth week was not appreciably different from that at the beginning of treatment. Patient 4 was much better during the third and fourth weeks with good appetite, regeneration of lingual papillae and resolution of dermatitis; during the last two weeks there was loss of appetite, recurrence of nervousness and weakness and dermatitis of the nose; the tongue remained good. The remaining five patients, 3, 5, 9, 13 and 15, began to show definite signs of relapse during the fourth and fifth weeks, glossitis recurred in all, and diarrhea

appeared and became severe in case 9. The other four lost appetite, weight and strength and patient 13 became severely demented and was hospitalized.

The tables, which record the condition of the two groups at the beginning and end of treatment, do not reflect the rather dramatic early improvement and later regression of the patients treated with nicotinic acid. A factor which cannot be neglected is the actual food value of the yeast given the control group as well as the possible effect of the vitamin B₁ and various fractions of B₂. The addition of somewhat over 300 calories, including approximately 40 Gm. of protein of good biologic value, to the daily ration of these people is important. The nicotinic acid content of the daily dose of yeast was probably about 15 mg.

SUMMARY AND CONCLUSIONS

1. Thirty-three known chronic pellagrins were selected from a large number applying for preventive

Summary of results obtained in patients treated with 100 mg. of nicotinic acid twice weekly from March 16 to April 27, 1933. The figures in the columns under the signs and symptoms listed indicate severity: 1, mild; 2, moderate; 3, severe; 4, very severe.

* indicates chronic alcoholism.

treatment. Sixteen were treated with nicotinic acid given in doses of 100 mg. twice weekly; seventeen were used as controls and given 90 Gm. of brewers' yeast daily. The observation period was six weeks.

2. In the group treated with nicotinic acid only one patient showed definite improvement at the end of the period. Nine improved for about four weeks and then regressed to about the same status as at the start of the experiment. One patient after good early response was slightly worse at the end, while five who also showed much gain during the first two weeks of treatment were definitely in relapse at the end of the sixth week.

3. In our hands nicotinic acid in doses of 100 mg. twice a week has not been effective in preventing relapse in known chronic pellagrins.

4. From experience in the treatment of acutely ill patients we feel that it is likely that a small daily dose of nicotinic acid may prove more effective or even entirely satisfactory. It is unlikely, however, that nicotinic acid without some improvement in the diet will prevent relapse indefinitely in chronically malnourished individuals.

Clinical Notes, Suggestions and New Instruments

POSTMORTEM CESAREAN SECTION IN TWIN PREGNANCY WITH DELIVERY OF TWO LIVING BABIES

D. A. HARRISON JR., M.D.; J. H. SHELTON, M.D., AND
C. M. CARRITHERS, M.D., KINGSVILLE, TEXAS

Since there are so few reports of twins in the literature, it occurred to us that a brief report of the case here reported might be of interest. At the present writing we have been unable to find another report in which twins delivered by postmortem cesarean section have lived for any length of time.

Postmortem cesarean section is one of the oldest practices in obstetrics. Even the old Roman law of Numa Pompilius, the Lex Regia of 715 B. C., decreed that no pregnant woman should be buried until her child had been removed from her womb. Ancient mythology referred to the birth of Bacchus and Aesculapius in this manner. There are laws in the Talmud and of the Roman Catholic church making this imperative.

Of all the postmortem sections done, until comparatively recent times very few living babies have been delivered.

Schops¹ reported statistics on a series of 107 cases from 1836 to 1846 in which not a single living child was extracted. He also reported another series of ninety cases from 1852 to 1868 in which there was no living child. Bohmer² has reported a series of cases in which only 60 per cent of the deliveries were of living babies. Pfaff reported fifty-two cases with twenty-two living children and thirty dead. Schwarz reported 107 cases in 1862 in which there was no living child. In 1914 Hallman collected sixty-eight cases from the literature in only from 61 to 68 per cent of which were there deliveries of living babies. Harrar,³ in reporting his ten cases of postmortem section, reports that three babies were stillborn, five were born alive but died in a short time, one baby was born alive but died on the sixth day of pneumonia, and the last two were living babies and were discharged from the hospital in good condition. In one of his cases there was a twin pregnancy; both babies were born alive but died in about twenty minutes.

Yule⁴ in 1926 reported a twin pregnancy in which the first fetus was delivered dead and the second, about ten minutes later, was extracted and lived.

Numerous other cases have been reported in the recent literature, in most of which the baby has lived. The following are only a few of the reports:

Hoffman⁵ in 1935 reported a case of a section done on a woman dying of convulsions, in which a live baby was delivered.

Roberts⁶ in 1925 also reported a case in which a woman died in a convulsion, with delivery of a living baby.

Phaneuf⁷ says that he has delivered three living babies by postmortem section.

Fallon⁸ in 1926 reported two cases in which delivery of living babies took place, both mothers having died of eclampsia.

Rider⁹ reported a case in 1931 in which the baby lived.

Campbell and Miller¹⁰ reported a case in 1931 in which a living baby was delivered.

Rosin¹¹ also reported a case in 1927 in which a section was done fifteen minutes post mortem and the child lived.

Holden¹² reported a case in 1932 in which a primipara died in convulsions and a postmortem section was done, saving the life of the fetus.

There are a few factors of importance that determine the possibility of extracting a living child. The main one of these is the element of time. De Lee¹³ has stated that a fetus will live if delivered from five to twenty minutes after the death of the mother. Hallman² states that the prognosis is better for the child in "sudden, rapid and violent death, disease of the central nervous system, heart and kidneys, than after long continued or infectious diseases, diseases of the blood, or intoxications in which the blood is altered."

The question of civil or criminal responsibility is to be thought of by any physician who performs a postmortem cesarean section without the consent of the husband or next of kin. This question is still one of controversy and has not been firmly settled. Reichmann, however, makes this statement:

"I cannot escape the conclusion that, given a case in which, in the light of existing scientific knowledge, the belief is reasonably justifiable that the infant may be rescued and its life saved, a cesarean section will be justified by the law on grounds of public policy and the person performing the same will be fully protected, both civilly and criminally, though performed without consent, or even against the protest in those in whom the law has recognized a legal right to the possession of the body of the deceased, provided, of course, the operation be performed in good faith and with due skill and without unnecessary injury or mutilation."

Other legal authorities have fairly well agreed that there is neither a civil nor a criminal violation in doing a postmortem section, even without the consent of the next of kin. Bacon even made this statement: "The obligation to save the human fetal life, when it can be done without destroying or seriously jeopardizing another life, is absolute."

A few authorities are of the opinion that this procedure is usually distasteful to all concerned, but most of them are of the opinion that the physician is morally obligated to do all possible in trying to save fetal life after the death of the mother.

REPORT OF CASE

Mrs. D. C., aged 41, an octipara, presented herself at our office about 11 a. m., Aug. 31, 1937, because of shortness of breath, which was so marked that she had been unable to sleep for the past two weeks unless she was sitting upright. She was pregnant—almost at term—the estimated date of confinement being about September 15. Her youngest child was 5 years of age, and she stated that she had had no trouble with any of her previous pregnancies. She had an increasing amount of edema, which had begun in her feet and legs four or five weeks before and had become so marked that it extended upward to the lower part of the chest. On hurried examination (the woman was quite dyspneic and it was our intention to hospitalize her as soon as possible) these significant observations were made: Both lower extremities and the abdomen were enormously distended with edema; she was very uncomfortable because of the shortness of breath; her facial expression was typical of that of patients with advanced heart disease who have become decompensated. The cardiovascular system showed a pulse rate of from 90 to 100, which was bounding and full with a moderate sclerosis of the radials. The blood pressure was 190 systolic and 110 diastolic, and every valve was apparently incompetent. There was a great deal of hypertrophy and dilatation. Moist rales were present in the base of both lungs. There was so much edema of the abdominal wall that it was impossible to make out anything definite on palpation of the abdomen. The impression was that the condition was hypertensive heart disease which had become decompensated because of the added load of the pregnancy. She was hospitalized immediately and orders were left for the administration of morphine for rest and four 1½ grain (1 Gm.)

tablets of powdered leaf digitalis every six hours for twenty-four hours. Her weight was about 180 pounds (81.6 Kg.).

At about 5:30 p. m. we were informed that the patient had just had a severe heart attack. We reached her bedside in about fifteen minutes and found her unconscious, pulseless, with frothy fluid exuding from the nose and mouth. She undoubtedly had a severe acute failure on the left side. The pupils had already become dilated and respiration was only in gasps. Epinephrine, caffeine and pyridine betacarboxylic acid diethylamide (coramine) were administered without effect. We did everything possible for the next ten minutes, including artificial respiration. Dr. Carrithers was present and when her heart sounds became inaudible one of us (D. A. H.) took the scalpel and immediately opened the abdomen and uterus. A boy was extracted with a weak cord pulsation of about 60 per minute. After two or three minutes, during which time efforts were being made to resuscitate him, there was a weak cry, and he was in fair condition. I turned to inspect the abdominal wound and noticed the arm of another fetus in the uterus, which was full of amniotic fluid. A baby girl was quickly extracted and found to have a cord pulsation of between 30 and 40 per minute and very weak. This was approximately seven or eight minutes from the time the woman was pronounced dead and about thirty-five minutes from the beginning of the patient's acute attack, during which time she had been practically pulseless. After about forty-five minutes' work at resuscitation, during which time alpha-lobeline and caffeine with sodium benzoate were administered in large doses and prolonged mouth to mouth insufflation was instituted, the girl uttered a weak cry. The twins were placed in the incubator for about eighteen hours, after which time they were in fair condition. After a stormy period of about a week the little girl's condition became fairly good. The birth weight of the boy was 4 pounds 4 ounces (1,928 Gm.) and the girl's was 5 pounds 6 ounces (2,439 Gm.). At the present time both are perfectly normal infants and in good condition. The boy weighs 13 pounds 8 ounces (6,123 Gm.) and the girl weighs 12 pounds 10 ounces (5,728 Gm.).

TUMOR IN ABDOMINAL WALL FROM A PINE NEEDLE SWALLOWED SEVERAL YEARS PREVIOUSLY

HARRY L. SMITH, M.D., AND JAMES T. PRIESTLEY, M.D.
ROCHESTER, MINN.

A white man, aged 40, whose family history was not significant, underwent a tonsillectomy in 1925, a stone was removed from his left kidney in 1926, and he had a sore throat in 1935; otherwise the medical history was essentially negative. In July 1937 he noticed slight soreness in the right groin. This remained for a few days and then disappeared. In August he again noticed a slight soreness in the same region. He applied an ice bag and the soreness disappeared in a few days. In November 1937, soreness and stiffness developed in the right lower quadrant of the abdomen. Since it came on a day after playing baseball, the patient attributed the pain to this. At this time he first noticed a hard lump just above the crest of the ilium. Because of this lump the patient then consulted a physician and several roentgenograms were taken. These were negative. The patient came to the clinic Jan. 13, 1938.

On admission the patient was well developed and well nourished and did not appear ill. Physical and laboratory examinations gave essentially negative results except for a hard mass in the right lower abdominal quadrant. Just above and medial and apparently fixed to the iliac crest was a stony mass about 6 cm. in diameter. This mass felt like a bony tumor; it was not tender. Many roentgenograms were taken but none revealed any involvement of bone. It was first believed that this tumor was a chondroma, since chondromas often do not produce a roentgenologic shadow.

At exploratory operation, January 19, a hard fixed mass was found just medial to the right anterior-superior spine of the ilium. The tumor was exposed by cutting through the external

From the Section on Medicine (Dr. Smith) and the Division of Surgery (Dr. Priestley), the Mayo Clinic.

oblique muscle. While hard, the tumor appeared to be inflammatory, which fact was confirmed by the pathologist. Deeper dissection into the center of the mass exposed an old pine needle, which measured about 4 cm. in length. This was removed and several small sinus tracts surrounding the pine needle were curetted. The wound was left entirely open, packed with iodoform gauze and permitted to heal by granulation. Convalescence was uneventful.

After operation, additional information was obtained. The patient was found to have worked for a lumber company from 1926 to 1929. During this period he was out in the woods most of the time. On his daily horseback rides through the woods he would often pick pine needles from the trees and, placing one in his mouth, chew on it. This had become quite a habit. He did not, however, remember having swallowed a pine needle.

Evidently this patient had swallowed a pine needle some time between the years of 1926 and 1929 and it had worked through the intestinal wall without producing any noticeable symptoms. There were no symptoms until a few months prior to operation, when an inflammatory reaction developed around the needle, but even then the symptoms consisted only of slight soreness in the side. It was because of this soreness that the mass was finally discovered.

THE ACOUSTICS OF THE STETHOSCOPE

DOUGLAS MACFARLAN, M.D., Philadelphia

The considerable number of variously designed stethoscopes on the market would lead one to judge not only that there is much difference in taste but that there is probably a difference in quality. More than this, it would seem important for one to know something about the variability introduced by an instrument for the examining of acoustics and something about the sounds to which one is listening.

TABLE 1.—Normal Heart Sounds (After Williams and Dodge)
Frequency Distribution in Energy Percentage

Frequency	Energy
50-60	56%
60-70	28%
70-80	10%
80-90	4%
90-100	2½%
100-110	1%

Above these frequencies the intensities are negligible.
Low pitched heart murmurs contain as their characteristics frequencies below 400 cycles.
High pitched murmurs range from 120 cycles to 660 cycles.
Presystolic murmurs lie for the most part below 140 cycles but may contain characteristics up to 400 cycles (Cabot and Williams).
Diastolic and systolic murmurs range chiefly between 120 and 660, occasionally ascending to 1,000 cycles.
The pericardial rub contains frequencies between 140 and 660 cycles.
Rales lie between 120 and 1,000.
Amphoric breathing ranges between 240 and 660 cycles.
Bronchial breathing ranges between 240 and 1,000 cycles.

The intensities of the sounds of the heart and the chest¹ are very small, not averaging, for the frequencies they possess, more than 10 decibels in their greatest exaggerations. The frequency characteristics of these various sounds are contained in a very narrow band between 60 and 1,000 cycles. In other words, whereas the normal hearing range lies roughly between 64 and 26,000 cycles, for listening to chests and hearts one is required to have good hearing only in the zone 64-1,000. Yet a small hearing loss in this restricted area will make the usual heart and chest sounds inaudible.

One factor of much importance in auscultation is a quiet examining room, for it requires only a small amount of outside noise to dampen out the sounds one wishes to hear.

It is also important to remember that hearing is greatly reduced by any (even slightly) increased pressure of the air column on the drum. Thus, tightly fitting ear tips held in place by strong springs will cut down efficiency.

It is apparent that, the larger the area of the stethoscope piece in contact with the chest, the greater the amount of sound collected; thus the diaphragm types when large collect more sound than the smaller "bell" types. Yet the latter have an advantage in more closely localizing the spot of greatest loudness. It will perhaps be a surprise to learn that the

TABLE 2.—Frequency Response of Nine Different Stethoscopes in Terms of Decibel Gain or Loss in Loudness

Frequency	128	256	512	1,024
No. 1 diaphragm type.....	-10	-5	0	-5
No. 2 diaphragm type.....	+10	-5	-10	-7
No. 3 diaphragm type.....	0	0	-5	-10
No. 4 Bell type.....	0	0	+2	-3
No. 5 Bell type.....	+5	+10	-5	-10
No. 6 Bell type.....	+5	0	-5	-5
No. 7 Bell type.....	-25	-15	-25	-20
No. 8 Bell type.....	0	0	-5	-5
No. 9 Bell type.....	-5	-5	-10	-5

unaided ear operates at greater efficiency than the ear aided by any type of stethoscope. A "frequency hearing run" of nine stethoscopes bought in the open market showed that for the most part sounds were not magnified but reduced in audibility. Table 2 shows in decibels the gain (+) or reduction (-) in hearing of these middle range pitches. It might appear from this that the best policy would be to buy the least expensive stethoscope one can find and then not use it. In this connection it is interesting to recall that David Livingstone was nearly "plucked" for his medical degree because he considered the stethoscope of doubtful use. But localization of sound is often of great importance, and the small bell stethoscope can best do this.

The most careful localization, however, can be done by using the phase difference phenomenon first expounded by Nicolai and later by English investigators, and in this country by Halverson, Stewart, Bunch and Seashore.² Such studies were developed by the war time necessity of submarine detection. In 1937 Kerr, Bassett, Goldman and Althausen of the University of California developed the idea in a double stethoscope, the symballophone.³

In using this method of localization it is necessary that the examiner hear equally well in the two ears. Very small differences in intensity can be detected.

QUALITY

No instrument can improve on the unaided ear against the chest to appreciate the subtle qualities of the sounds of the heart and the chest. The examiner's "opposite" ear must, of

course, be stopped up. Unfortunately, the configuration of the chest makes it difficult for the unaided ear to localize sound in small areas.

Conduction of sound in the chest depends on the factors of flesh and bone. An adipose chest wall or extensive fatty breasts will surely absorb much of the sound. The stethoscope, fol-

3. The symballophone was presented in the Scientific Exhibit of the American Medical Association in Atlantic City, N. J., in June 1937.

lowing along the prominence of the ribs, will often be misleading as to the direction of transmission of sound.

For those physicians with impaired hearing, the advent of the crystal microphone has made it possible for them to feel that auscultation, with all its importance, is not in the discard. This type of microphone is extremely free of distortion.

Amplification, however, is neither practical, nor desirable, nor is it needed for the physician with normal hearing.

1805 Chestnut Street.

OXYGEN SATURATION OF ARTERIAL BLOOD IN THE CYANOSIS FROM SULFANILAMIDE

FREDERICK H. KING, M.D., AND ALAN LESLIE, M.D., WITH THE TECHNICAL ASSISTANCE OF GRACE BYRNE, NEW YORK

A majority of the patients to whom sulfanilamide is administered in large doses show cyanosis in varying degree. This has been attributed by various authors to decreased oxygen saturation¹ methemoglobinemia² and sulfhemoglobinemia.³ Although the latter two may occur in some cases, they do not assume a principal role in most instances, as has been demonstrated by Marshall and Walzl.⁴

We have investigated the oxygen saturation of the arterial blood in eight patients to whom sulfanilamide was administered in fairly large doses. In each instance there was a grayish blue cyanosis during the administration of the drug. In no instances were there any clinical manifestations of anoxemia. Blood specimens, withdrawn for analysis, were uniformly dark.

Blood was drawn from the brachial artery under anaerobic conditions and collected under oil, following which the determinations were promptly made. The oxygen content and capacity of the blood were determined by the methods of Van Slyke and Neil.

unsaturation) of the arterial blood does not play a significant role in the cyanosis from sulfanilamide. This is in keeping with the clinical observation² that the administration of oxygen in these cases fails to influence the cyanosis.

AN OUTBREAK OF JAUNDICE IN DETROIT PRELIMINARY REPORT

JOSEPH G. MOLNER, M.D., AND JOSEPH A. KASPER, M.D.
DETROIT

Following the recognition of a disease characterized by fever and jaundice by Weil in 1886, series of similar cases were reported by other investigators. Inada and Ido and their associates¹ in 1914 described the same malady as it occurred in Japan, and after careful investigation these workers concluded that the etiologic agent was a spirochete. Other cases were reported by workers from England, Germany, France and the Netherlands. Particular attention in most of these reports is directed to the significantly high incidence of the disease among soldiers in trenches.

Noguchi² in 1917 described the organism isolated in cases of jaundice in greater detail. He classified it a *Leptospira icterohaemorrhagiae*. In a later publication of his studies he reported finding virulent strains of *Leptospira* in carcasses of rats trapped in New York. These organisms were found to be pathogenic to guinea pigs and agreed in immunity and agglutination reactions with the Japanese strain isolated by Inada and Ido and their associates. Repeated isolations of similar strains of *Leptospira* from rats were reported by Jobling and Eggstein,³ Langworthy and Moore⁴ and others.

Weil's disease is most generally encountered as a sporadic disease, occurring primarily in localities that are heavily infested

Observations in Eight Cases

Case	Diagnosis	Date	Cyanosis	Total Dosage of Sulfanilamide to Date	Hemoglobin, per Cent (Sahli)	Oxygen Content, Volumes per Cent	Oxygen Capacity, Volumes per Cent	Oxygen Saturation, per Cent

The accompanying table discloses the fact that in no instance was the oxygen saturation of the arterial blood at a point low enough to explain the relatively marked cyanosis. In cases 4 and 7 the cyanosis was the most marked in this series and the initial determinations revealed oxygen saturations of 91 per cent and 91.2 per cent. Repeated determinations in several instances showed a fall in both oxygen content and capacity. The factors responsible for the decreases cannot be evaluated from so small a group of cases. The percentage of oxygen saturation, however, never fell to a point to warrant considering it a significant causative factor in the cyanosis.

The observations made on this group of eight patients would tend to indicate that diminished oxygen saturation (increased

with rats. Another common environmental association with this disease includes moist or muddy conditions. Persons working under such conditions as, for example, miners, sewer workers, fish cutters, bargemen, butchers and garbage handlers are most prone to acquire the disease. These environmental conditions may account for the greater incidence among men.

Outbreaks of jaundice in civil populations have been reported in England⁵ and in the United States.⁶ The distinguishing feature of such attacks, as compared to Weil's disease, was the apparent insidious nature of their onset and the tendency to

occur in outbreaks. Epidemic jaundice primarily affects children and occurs more generally during the fall and early winter months. Its clinical course usually extends over a period of about two weeks. Moderate hyperpyrexia is usually noted, and seldom does the illness terminate in death. The etiology of this type of jaundice is unknown, although it has been postulated by some investigators that a strain of spirochetes of low virulence, or possibly a filtrable virus, may be the causative agent.

In the early part of January 1938 our attention was called to a sudden increase in the incidence of jaundice among school children. A group of five patients were suffering from a moderate form of this disease. In rapid succession, and in the same locality, our attention was called to twelve additional cases, one of which was fatal. By investigation of the current cases and by retrospective inquiry, which included the period extending back to November 1937, we have been able to uncover a total of forty cases. One of the patients was a boy aged 3, another was a youth aged 16, and still another was a man. The remaining thirty-seven cases were distributed in the age group from 5 to 15 years.

There was a very definite aggregation of cases noted in this group. The majority of the cases were reported from the west side of Detroit. The localities primarily involved were the far north, far south and central areas of the west side of Detroit. Twelve cases were reported from one elementary school. Multiple cases have occurred in five families.

The condition apparently is infectious in nature, and person to person contact may play an important role in the transmission of the disease. In 60 per cent of instances contact with other cases was established.

Two outbreaks of jaundice in kennels have been investigated. Curiously, both of these outbreaks occurred in the late fall of 1937 and in localities where, at the present time, human cases are showing evidences of aggregation. In both of the kennel outbreaks infestation with rats was noticed by the proprietors. The outbreak of jaundice among the dogs affected animals under 6 months of age. The case fatality among these was 50 per cent. One of the kennel outbreaks was superficially investigated, and liver scrapings from two of the dead animals revealed the presence of organisms having the structure of spirochetes. These observations, however, were not followed by inoculations of guinea pigs.

In another instance, again in the section of the city in which human cases show evidences of aggregation, there is the history of a fox terrier having been bitten by a rat. The history was definite and verified. The dog, three days after injury, became ill with nausea, vomiting and loss of appetite. On the fifth day of illness frank jaundice, clay-colored stools and dark urine were noted by the owner. The dog failed to take food from the fourth day of onset of his illness and died on the eighth day of the disease. The observations at autopsy, performed two weeks after death, were petechial hemorrhages throughout the mesentery, liver and lungs, together with definite signs of jaundice. These observations, however, were obscured by autolytic changes that had developed.

Our investigation of the fatal case—the 3 year old boy—shows that the disease was ushered in with a chilly sensation but no definite chills, which was followed by fever. The temperature ranged from 99.6 to 103 F. Concurrently with the chilly sensation and temperature elevation nausea, vomiting, lethargy and loss of appetite developed. On the fourth day of illness coryza developed, at which time the patient was seen by a physician.⁷ On the sixth day highly colored urine was noted, and on the seventh day frank jaundice developed. Within three days after the onset of the jaundice apparent recession of the symptoms was noted. Convalescence continued for five days, when it was interrupted by an acute exacerbation evidenced by the recurrence of the chilly sensation and the rise in temperature. Clinically the child became more acutely ill and died on the twenty-first day of his illness, after lapsing into terminal coma.

Antemortem and postmortem specimens of blood taken from the child revealed spirochetes on dark field examination. Liver scrapings were also found to contain spirochetes. Samples of

blood and urine inoculated into guinea pigs failed to produce jaundice in these animals. The patient's blood serum showed agglutination of *Leptospira icterohaemorrhagiae* in a dilution of 1:30,000, which was reported and considered diagnostic by the National Institute of Health.

Probably one of the most intriguing circumstances in the course of our investigation arose in the follow-up of the foregoing case. The first case of jaundice in a dog was encountered in a Scotch terrier owned by this family. The dog became ill about fourteen days prior to the onset of the child's illness. The dog's illness was characterized by nausea, vomiting, listlessness and loss of appetite. Within two days clay colored stools and highly colored urine were noted. A veterinarian was consulted and the condition was diagnosed as jaundice. Although the animal's condition was considered hopeless, convalescence was surprisingly uneventful and the dog was returned to the owner in ten days. It was within the following two days that the child in this family became ill.

SUMMARY

An outbreak of jaundice has been noted among children and adults in Detroit.

The causative agent in this outbreak is as yet undetermined. Agglutination of *Leptospira icterohaemorrhagiae* in a titer of 1:30,000 was found in one case, which terminated fatally.

Jaundice among dogs was observed. In one instance the disease in the dog was followed by a similar malady in the owner.

Investigation reveals that contact of dogs with rats may be followed by jaundice in the former. Of six young dogs in which jaundice developed three died of the disease.

The observations here reported warrant further investigations relative to *Leptospira icterohaemorrhagiae* as the cause of jaundice in Detroit. Virus as a possible etiologic agent, as suggested by Bates,⁶ might also bear investigation.

A FINGER SPLINT FOR EXTENSION OR FLEXION

NED SHNAYERSON, M.D., NEW YORK

This instrument is a device presented to obviate the difficulties one meets in the treatment of the "stiff finger."

When the patient presents a loss of function of the metacarpophalangeal or interphalangeal joint not due to ankylosis, one tries to overcome the fixed position of flexion or extension by

Fig. 1.—Splint for extension or flexion of finger.

a constant force in the direction desired. Many devices have been utilized to accomplish this, such as a plaster cast with overhanging surface so that felt pads may be wedged in between this surface and the fingers, and elastic bands applied to the end of the finger or finger nail. All these devices are usually cumbersome and apply an inconstant and inefficient force.

The device here presented is a metal splint which has a corresponding joint for each joint in the finger. In figure 1 the middle two segments A-B correspond to the two proximal

7. This case was reported to the department of health by Dr. Edgar E. Martner.

segments of the finger and can be lengthened or shortened, according to the patient's finger length, by a lock C. When the splint is fixed in place, the affected joint or joints can be flexed or extended into a constantly increasing or decreasing angle by turning the turn-screw D. The patient does this manipulation himself, so that the increase of flexion or extension is constantly applied and the angle desired more quickly

Fig. 2.—Use of part of splint when only one joint is affected.

obtained. This angle is held in position without any return to the old position for as long a period as is desired. The splint is applied by encasing the segment E-F in a plaster bandage around the hand. This will hold the instrument in a rigidly correct line. The middle segments are adjusted to the proper lengths and some padding is placed between the finger and the under surface of the splint. A turn of narrow adhesive plaster around the segments of the finger and the splint will complete the application of the instrument. If only one joint is affected, the splint can be taken apart and only the corresponding part applied to the affected joint (fig. 2).

Mr. Frank Smart cooperated and contributed the mechanical ingenuity required in overcoming the difficulties in making the joints of this device pass through a 90 degree span.

45 East Sixty-Second Street.

A CASE OF POLYCYTHAEMIA VERA: THE FAMILIAL INCIDENCE OF HEMOPHILIA AND TREATMENT WITH PHENYLHYDRAZINE

SIDNEY M. GLASSER, M.D., HEMPSTEAD, N. Y.

In reviewing the literature pertinent to polycythemia, one sees no mention of the etiologic aspect of this disease. There is free mention of the pathology, therapy and sequelae, but no observations cast any light on the cause of this rare condition. I am offering no theory as to the mechanism which results in erythremia, but it is of more than passing interest to note the appearance of two rare hematologic diseases in the same family.

REPORT OF CASE

History.—B. G., a white woman, aged 60, a widow, a member of an old New England family, first seen in November 1935. For two months the patient complained of nausea, vomiting, weakness, dizziness, a throbbing sensation throughout the head, discoloration of various parts of the body, neuralgic pains of the muscles and joints, and a marked distention of the abdomen.

The past history revealed the average childhood diseases, with menstruation commencing at 14 years and the menopause at 40, with no menorrhagia or metrorrhagia at any time. Two female children were delivered normally with no severe post-partum hemorrhage; there had been no surgical operations at any time except extraction of all the patient's teeth in 1923, which caused oozing for several days. The patient's mother, as well as herself, bled more than the average when they cut their fingers doing housework.

About seventeen years before admission the patient noticed a lump in the left upper abdominal region, concurrent with

purpuric spots over the body, cyanosis and frequent bilious spells. These attacks (occurring about five times a year) would last for about one week, incapacitating her, and appeared to be independent of menstruation.

In 1927 the patient had an episode similar to the present illness and was confined to bed for three months, at which time a diagnosis of polycythemia vera was made; at that time she was given a monthly superficial x-ray treatment for the spleen for seven months. In 1930 her attending physician commenced monthly phlebotomies of an average of 25 ounces (750 cc.) for about one year. Since then she had kept growing progressively worse and for the last five years had spent the major part of the time in bed.

Figure 1 shows the incidence of hemophilia in the patient's family; the youngest sister died at the age of 35 of hemorrhages following a laparotomy, but, owing to inadequate records, neither the diagnosis nor the cause of the hemorrhages could be ascertained. All of the patient's cousins and nieces are in good health and free from any bleeding tendencies. The patient's husband died at the age of 65 from rectal carcinoma. Death certificates extending back thirty years failed to reveal any hemorrhagic tendencies in the patient's grandparents.

Physical Examination.—The patient was extremely cyanotic, weighing 92 pounds (41.7 Kg.), and appeared to be about 75 years old; she was roused with considerable difficulty. The entire face was cyanotic; the cheeks were very prominent; the orbital fossae were sunken; ophthalmoscopic examination showed marked distention of the retinal veins with peculiar bluish tinting of the retina; all the teeth were absent; the thoracic cage was symmetric, with marked prominence of the intercostal spaces. There was visible a pulsation in the region of the fifth interspace just beyond the midclavicular line. The heart was enlarged about 3 cm. beyond the midclavicular line in this interspace. There was an apical systolic murmur transmitted toward the left axilla. Blood pressure was 170 systolic, 100 diastolic. The liver was palpable, four fingerbreadths below the right costal margin; it was not tender and was smooth. The abdomen was full and was distended with considerable tympany. The spleen was mapped out, having its distal border slightly below the left anterior superior spine with its medial border crossing the midumbilical line. The spleen was smooth throughout and was moderately tender. No other viscera were palpable; the extremities were emaciated, and no abnormal

Fig. 1.—Familial incidence of hemophilic deaths in B. G.'s family as indicated by the black figures.

neurologic manifestations were observed. Examination of the urine showed the specific gravity 1.014, with a faint trace of albumin.

Therapy.—Figure 2 shows the hematologic course of the disease under the influence of phenylhydrazine hydrochloride therapy, as recommended by Owen.¹ Levi² cautions against the use of this drug, since it may predispose to cirrhosis of the liver, yet I felt that if the patient were not treated she would

1. Owen, Trevor: The Treatment of Erythremia with Phenylhydrazine, J. A. M. A. 85: 2027 (Dec. 26) 1925.
2. Levi, E.: Erythremia, Ztschr. f. klin. Med. 100: 777, 1924.

die. Furthermore, Ryle³ is of the opinion that, since cirrhosis develops in the majority of untreated patients with erythremia if they escape other complications, it seems logical to conclude that their own inadequate method of destruction of blood is not necessarily successful.

Course.—The remission of the blood changes closely parallels the subjective symptoms. Blood pressure taken two months after the beginning of therapy fell to 155 systolic, 90 diastolic, and when last taken was 135/80. At present the patient is carrying on her full household duties and is assisting in chores. The last time she was seen the patient was doing a commendable job of papering the wall of her bedroom.

COMMENT

It would have been very illuminating to know whether this woman is a transmitter of hemophilia, but no male progeny have been borne to either of her daughters or to herself. It is to be expected that a male child would probably have shown

Fig. 2.—Hematologic response to phenylhydrazine therapy.

evidence of hemophilia. The hematologic manifestations in this case are far more severe than those usually found in this condition. Howell⁴ states that when the red blood cells reach a level of 13,000,000 per cubic millimeter the viscosity of the blood will be such as to cause spontaneous thromboses.

CONCLUSION

In the case of severe polycythaemia vera presented here in which all male members of the patient's family died of hemophilia, a dramatic response was shown to phenylhydrazine hydrochloride therapy.

The Spirit of Medicine.—Descartes, in the sixteenth century, once said, "If ever the human race is raised to its highest practicable level intellectually, morally, and physically, the science of medicine will perform that service." I would substitute the word spirit for science, for it is, after all, the spirit of medicine that has sustained us.—Borzell, Francis F.: *The Medical Profession and the Social Worker, Pennsylvania M. J.* 41:683 (May) 1938.

Special Article

VITAMIN A

PHYSIOLOGY AND PATHOLOGY

OTTO A. BESSEY, Ph.D.

AND

S. B. WOLBACH, M.D.

BOSTON

This article and others recently published or to be published comprise a new series on the present status of our knowledge of the vitamins. They have been prepared under the general auspices of the Council on Pharmacy and Chemistry and the Council on Foods. The opinions expressed are those of the authors and not necessarily the opinions of either council. Reprints are not available but the articles will be published later in book form.—Ed.

Vitamin A is an essential part of the biochemical machinery of all vertebrates. It is a derivative of carotenoid pigments from plants. As far as is known, no vertebrate can synthesize carotenoids *de novo*.¹ Probably all higher animals can convert certain carotenoids to vitamin A. The pathologic consequences of the deficiency are similar in man, monkeys, cattle, swine, dogs, rabbits, guinea pigs, rats, mice and fowls.² For these and other reasons, facts about vitamin A learned from animal experiments are without doubt applicable to man.

The required brevity of this article will not permit mention of many papers and excludes critical discussions. The selection and evaluation of the material presented are expressions of our judgment. Readers wishing more references are referred to a monograph by Browning,³ to a review by Robertson⁴ and to the recent volumes of the *Annual Review of Biochemistry*.⁵

PHYSIOLOGY

Vitamin A and Carotenoids.—Fats, carbohydrates and proteins constitute the bulk of the physical basis of living matter and serve as the principal source of energy. Vitamins have to do with those biochemical mechanisms which are concerned with the transformation of food and energy into the many forms of activities essential to normally functioning organisms. Quantitatively the requirement for vitamin A is strikingly small; at most only a few milligrams daily are necessary for the largest mammals.⁶

Carotenoid pigments,⁷ yellow and red compounds, are widely distributed in the plant world from bacteria and diatoms to garden fruits and vegetables. Four substances, out of this large group, are known at present from which animals can form vitamin A. These (provitamins) have been named alpha, beta and gamma

carotene and kryptoxanthin. (A preparation of a carotenoid, echinenone, from the sex glands of sea urchins, has been found active as a provitamin A.) The chemical nature of these substances has been discussed in a previous paper of this series.⁸ The term carotene will be used in this paper to represent the group of provitamins.

Carotene is obviously of great importance in the physiology of plants, though its exact function is unknown.⁹ It usually appears concurrently with active growth and function and seems to be closely associated with chlorophyll in assimilative activities. Etiolated shoots contain little carotene while green shoots contain much, a fact that suggests the influence of light in the formation of carotene as well as of chlorophyll. In general, the quantity of chlorophyll is an index of the carotene content of green plants. Carotene does not seem to be consumed by any plant activity carried on in the dark, nor is it lost when the chlorophyll disappears at the time of yellowing of leaves. It is, however, completely destroyed in dry dead leaves. Rapid drying by artificial heat of freshly cut alfalfa destroys enzymes in the plant which in field curing are responsible for extensive inactivation of provitamin A. This fact is important because the carotene of green leaves is brought indirectly into human nutrition through milk and eggs. In human nutrition a considerable part of the vitamin A value, or activity, is represented by carotene in green and yellow vegetables.¹⁰ Eggs, milk and butter are the usual sources of vitamin A but they also furnish some carotene, the proportions depending on the nutritional state of the hen and of the cow.

Except as a precursor of vitamin A, carotene as such is not known to be active in the animal economy. However, the problems of absorption, assimilation and storage of carotene and the relationship of carotene to the secretion of milk and the production of eggs must be considered in any discussion of the physiology of vitamin A.

Storage of Vitamin A in the Body.—Most animals have a remarkable capacity for the storage of vitamin A, illustrated by the fact that a rat may in a few days store enough vitamin A to supply its nutritional needs for several months.¹¹ Approximately 95 per cent of the total vitamin A in the body is present in the liver; small but detectable amounts appear in the lungs and the kidneys.¹² In times of low intake this store is used to supply physiologic needs. During a prolonged deficiency, the reserve is gradually depleted, normal cell functions are suspended and pathologic change develops. In the rat this storage, physiologically speaking, seems to be of two types. By excess feeding of concentrates, enough vitamin A may be accumulated in the liver theoretically to supply normal requirements for several years. However, this supply decreases at a reasonably rapid rate, beginning immediately after the concentrate is withheld, until it reaches a level at which a more conservative mechanism governs its use. A sufficient supply remains to nourish the animal for some time, even on a deficient diet. In

general, the reserves of the liver parallel the dietary intake but may represent only a fraction of the total consumption.¹³ In human beings, as in all animals studied, the vitamin A content is much lower in the liver at birth, irrespective of the diet of the mother, than in the liver of the normal adult.¹⁴ Accumulation of vitamin A in the liver tends to increase with age and is dependent on the character of the diet.

In the rat, neither general emaciation nor specific starvation due to other vitamin deficiencies has an influence on the hepatic reserves of vitamin A.¹⁵ Chronic diseases and infection seem to lead to slightly lowered vitamin A reserves, probably owing either to reduced intake of vitamin A or to decreased assimilation in the alimentary tract and increased metabolic demands.¹⁶ If one is to judge from autopsy material, nephritis and other diseases of the kidney and bladder definitely lower the vitamin A reserves. As yet the evaluation of data from such material is complicated by the uncertainty of what the normal reserves should be. Even assuming that the reserves are lower than normal, one has the added difficulty of deciding whether the lowering is cause or effect. One might expect greatly decreased reserves in association with severe disease of the liver, but existing data do not allow a conclusion on this point.

The vitamin A concentration of the liver of man,¹⁶ the rat,¹⁷ the cow⁶ and the rabbit when the subject is well nourished but not "flooded" with vitamin A is from 200 to 400 international units per gram, or from 10 to 20 mg. per hundred grams. The content of chicken liver seems to be much higher under these conditions of stable saturation.¹⁸

The problem of the storage of vitamin A in the livers of fish is interesting from both the commercial and the physiologic point of view.¹⁹ Certain species of fish, such as the halibut, yield liver oil of several hundred times the vitamin A potency of the average cod liver oil. As much as 1 per cent of the weight of halibut livers may be vitamin A. It is difficult to understand how this percentage could be stored vitamin derived from food only, especially since the diet of the halibut seems to be quite low in vitamin A. Of course the possibility exists that, although the concentration of the vitamin in the food is low, the large amount eaten, with gradual accumulation and unusual economy, in time leads to large reserves. That the reserves of the Newfoundland cod increase with age is evidence in support of this view. Phytoplankton, small marine algae, serve as the ultimate source of food for most sea animal life and have been found to contain biologically active carotene. The hypothesis is that these small plants are ingested by small crustacea or little fish, which in turn are eaten by larger fish, and so on, until the carotene of microscopic aquatic plant life becomes converted and stored as vitamin A in the livers of the larger fish. One of the points of weakness in this

theory is the almost complete freedom from vitamin A or carotene of crustacea and copepods, the main articles of diet of the cod and the halibut. Crustacea and copepods do, however, contain pigments which originated from carotene and which, although not biologically active for a rat, may hypothetically serve as intermediates for synthesis of vitamin A by the fish. Another view could be that fish possess a power not present in mammals of synthesis from simple materials. This is pure speculation and has little experimental evidence to recommend it at present.

Absorption and Utilization.—Absorption and utilization of vitamin A and carotene are affected by the quantity administered and the manner of administration, the influence of other substances, the degree of saturation of the body and the general physiologic conditions of the alimentary tract.²⁰ The successful use of the rat test method for vitamin A activity is ample demonstration that amounts near the minimum requirements of either carotene or vitamin A are well utilized in this species. However, as the intake approaches a point which apparently exceeds the ability of the organism to absorb, convert and store, the efficiency decreases. Less than 10 per cent of an intake of vitamin A which is 2,000 times the necessary minimum is stored in the liver of the rat, while amounts which are not excessive but are satisfactory for optimum nutrition lead to 90 per cent storage.²¹ Absorption of vitamin A both in the rat and human being reaches a maximum in three to five hours after administration as shown by disappearance from the intestine and rise in the blood level.²² Under the same conditions carotene reaches a maximum level in the blood in from seven to eight hours. Fecal excretion accounts for only a small portion of the unutilized excess, the rest of which apparently finds other channels of excretion or is destroyed in the intestine or elsewhere in the body.²³ The other chief path of output, the kidney, seems to play no part in disposition of either vitamin A or its precursor unless the organism is literally flooded with vitamin A, in which case the vitamin is absorbed faster than it can be stored or destroyed and some "spilling" probably occurs into all body fluids.²⁴ This might be cited as evidence for the view that the organism possesses a mechanism for eliminating the unneeded excess by a destructive process, although delayed absorption undoubtedly results in some destruction in the intestine. The presence of bile²⁵ is not necessary but is helpful for absorption of vitamin A in the rat.

In general the assimilation of carotene is subject to great variations. Small quantities of carotene in oil are utilized under normal conditions to an extent of from 70 to 80 per cent, but it is generally agreed that larger quantities are not as well utilized as vitamin A.²⁶

This is especially true if the carotene is fed without being dissolved in oil or with low fat diets. A certain amount of normal absorption of fat seems necessary for transportation of carotene across the intestinal wall. On a fat-free diet rats assimilate only a small fraction of the same dose which is completely utilized when 10 per cent fat is included in the diet.²⁷ The importance of normal fat metabolism for absorption of carotene is further emphasized by the fact that in jaundice or choledochocolonostomized dogs the use of carotene is inhibited.²⁸ Some carotene is absorbed by rats with internal bile fistulas if bile acids are also fed. This fact suggests that bile acids directly or indirectly play a part in the transportation of carotene across the intestinal epithelium. One should bear in mind the possibility that a deficiency of vitamin A may arise in association with chronic diarrhea, obstruction of the biliary ducts, pancreatic dysfunction, celiac disease and other disorders involving prolonged faulty fat metabolism. In such cases absorption of carotene may be completely inhibited and assimilation of vitamin A greatly reduced.²⁹

The direct absorption of vitamin A and carotene into the thoracic duct was demonstrated in a case of chylothorax in which it was possible to drain the chyle for study.³⁰ Reasonably large quantities of vitamin A were returned almost quantitatively in the chyle, while the recovery of equivalent quantities of carotene was far short of quantitative. The carotene seemed to be chemically free, but the vitamin A appeared in a form which indicated that esterification had probably occurred in the intestine, a fact which may be significant in view of its natural high absorbability. Both substances were associated with the nondiffusible fatty phase, as was to be expected.

The simultaneous presence of liquid petrolatum shows little effect on the absorption of vitamin A but seriously diminishes the absorption of carotene by competing with the solvent action of natural fats.³¹ This emphasizes the desirability of giving liquid petrolatum separately from carotene-containing material.

During and for some time after certain infections, infants show diminished rates of absorption of carotene and vitamin A, which are not attributable to the accompanying fever, because elevated temperatures produced by other means have no such effect.³² The explanation of this interesting observation is not clear, but the phenomenon seems to be due to decreased intestinal absorption.

One may conclude that, under ordinary circumstances of moderate intake, carotene is slightly less efficient than vitamin A but that, when rapid storage of vitamin A is desired or when there is intestinal disturbance, products such as eggs, milk and fish liver oils are preferable to carotene.³³

Studies of the vitamin A and the carotene content of blood have been difficult because of the lack of satisfactory analytic methods for tissues of such low

concentrations.³³ The values for plasma carotenoid seem to be a measure of the difference between the rate of absorption from the intestine and the rate of conversion to vitamin A by the organism and not an index of nutritional reserves or intake. The vitamin A level in the plasma is subject to great variation even in normal, carefully controlled animals. However, it seems probable that refined methods will show consistent low values for the blood with deficiency, as compared with higher (although variable) values with normal nutrition. The concentration of vitamin A in the blood is independent of the quantity stored in the liver. Hardly enough work has been done on this subject to evaluate the significance of blood determinations.

After carotene is absorbed into the thoracic duct it is found in the liver in quantities dependent on the species. When a colloidal aqueous suspension of carotene is injected into the portal or systemic circulation, it is rapidly removed from the blood stream by the reticulo-endothelial system.³⁴ If sections of the liver are examined immediately after the injection, granules of pigment may be seen in the Kupffer cells. A greater part of the carotene is thus held in the liver, although carotene is held to a lesser extent elsewhere in the animal. The carotene in the Kupffer cells slowly disappears, and the concentration of vitamin A in the liver increases. Possibly the vitamin A of the liver also resides in the Kupffer cells, since livers which have had the parenchymal cells severely damaged by phosphorus poisoning, which supposedly does not harm the Kupffer cells, retain their store of vitamin A, and blocking of the reticulo-endothelial system by injections of certain particles lowers the capacity of the liver for storing vitamin A.³⁵ That the liver cells are necessary for the conversion of carotene to vitamin A is suggested by the fact that conversion is decreased by phosphorus poisoning³⁶ and, in certain diseases of cattle which involve the parenchymal cells, carotene remains unconverted in large quantities in the Kupffer cells.

It is important to note that in some cases carotemia is due to a low ability to convert carotene and not necessarily to a high intake. The rate of transformation of carotene is diminished by diabetes³⁷ and certain diseases of the liver.

The conversion of carotene to vitamin A in vivo is a slow, variable process, demonstrable only after several days, in the rat, rabbit, hen and cow, while there is some question as to whether it occurs at all in the cat, a carnivorous animal.³⁸ In view of this fact, it is not surprising that attempts to bring about conversion in vitro have been in general unsuccessful.³⁹ Thus cir-

cumstantial evidence suggests the liver as the site of the formation of vitamin A, although no direct proof is available.

Vitamin A and Milk.—The surprisingly low reserves of vitamin A in the newborn⁴⁰ make plain the necessity for an adequate intake of vitamin A during infancy. The vitamin A content of milk is therefore important. Since the conversion of carotene to vitamin A in the animal is not always immediate and complete, a certain amount of the vitamin A activity of milk, eggs and other biologic fluids and tissues is due to carotene, the proportion depending on the dietary intake of plant products and the efficiency of the transformation mechanism of the particular animal.⁴¹ It has been shown with cows consuming the same ration that about two thirds of the total activity in Guernsey milk is due to carotene, and this ratio remains rather constant as long as carotene is included in the ration; the carotene content of Ayrshire milk represents only about one third of the total activity, while Jersey milk contains about equal quantities of vitamin A and the provitamin. Thus the proportion of vitamin A activity due to carotene depends on the breed. It is an interesting fact that goat milk contains practically no carotene but that the vitamin A value remains remarkably constant even with considerable variation in rations.

One cannot conclude that the more highly pigmented milks necessarily have a higher vitamin A activity, for, although Guernsey milk may contain more carotene than other milks, it also contains less vitamin A, so the differences according to breed in total vitamin A activity seem to be small.

Most animals show a tendency to regulate the vitamin A content of their milk at a level characteristic of the species. In times of excess dietary intake, vitamin A accumulates in the liver and is used to stabilize the vitamin A content of the milk when the intake is less favorable.⁴² Although this stabilizing process is not comparable with the efficiency of strict physiologic control, the vitamin A level in milk remains reasonably constant during average dietary variations.⁴³

The extent to which the total vitamin A activity of the milk varies with the dietary intake depends on the nutritional state of the animal.⁴³ When the carotene intake of the cow is increased from a deficient level there is an immediate increase in both carotene and vitamin A in the milk; however, less influence is shown by each increment until a maximum is reached beyond which increased carotene intake does not affect the level of either carotene or vitamin A in the milk.

Cow's colostrum is from ten to one hundred times richer in vitamin A activity than milk, thus providing the calf with a concentrated food during the first few days of life.⁴⁴ There is no obvious variation in the vitamin A value of cow's milk with later periods of lactation.⁴⁵

Dann⁴⁴ has shown that the combined carotene and vitamin A content of early human milk has from about

five to ten times the biologic activity of cow's milk and is not appreciably increased by feeding supplements of cod liver oil* to the mother. Other investigators have reported that late human milk contains about the same amount of carotene and vitamin A as cow's milk. Human colostrum has from two to three times the biologic activity of early milk.

Vitamin A and Eggs.—Egg and milk formation are analogous biologic functions, and in general the vitamin A value of the egg is subject to the influences previously described for milk.⁴⁶ Dark-colored egg yolks are usually richer in vitamin A activity than light-colored yolks; however, pale eggs produced by hens on diets devoid of carotene and xanthophyll but containing cod liver oil are not appreciably lower in vitamin A potency. When the hen is on a deficient diet the vitamin A value of the egg will slowly decrease as the reserves of the liver are depleted, with a concomitant decrease in the production of eggs. Excess feeding of concentrates leads to considerable temporary increase of vitamin A

depend on light of high intensity, while the rods are sensitive only to light and are especially adapted to function in dim light.⁴⁹

The outside end of the rod which lies adjacent to the pigmented epithelium of the retina contains visual purple (rhodopsin) found only in the rods and serving to transform the energy of dim light into nerve impulses which vary, within limits, with the intensity of the light. Although the complete details of this photochemical process have not been ascertained, it has been suggested and considerable proof obtained that the cycle of events in the retinal rod when a molecule of visual purple receives a quantum of light energy is that shown in the accompanying illustration.⁵⁰

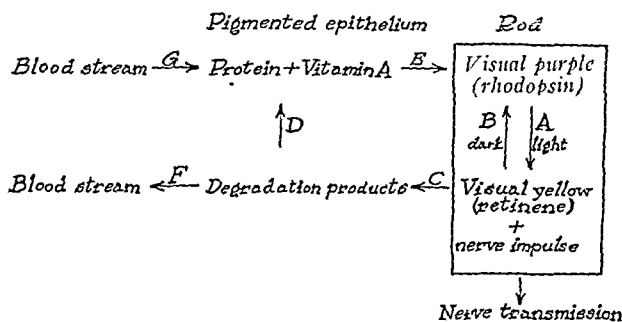

The photosensitive pigment (visual purple) absorbs the light and as a consequence is decomposed into products which initiate a nerve impulse (reaction A). Other chemical systems immediately intervene to resynthesize these products to a new molecule of receptor pigment (reaction B or C + D + E) or they are disposed of as waste materials (reaction F) and an entirely new molecule is made from fresh raw material to take their place (reaction G + E). The quantity of visual purple which is present at any instant will depend on the difference between the rate of decomposition (reaction A; intensity of light) and the rate of synthesis (reactions B and E). In bright light the equilibrium of these reactions is displaced so that visual purple is practically absent from the retina, while in the dark the equilibrium is displaced in the opposite direction and visual purple is present in maximum quantity. Normal vision in dim light, whatever may be the details of the reaction, depends on an equilibrium somewhere between these two extremes.

Two processes are proposed for the synthesis of visual purple: from visual yellow by simple reversal of photolysis and from the protein plus vitamin A with the aid of the pigmented epithelium. That a certain proportion of visual yellow or retinene is converted to visual purple is observed in the isolated retina which has been bleached and replaced in the dark; the remainder decomposes and is lost or resynthesized by aid of the pigmented epithelium. The latter process takes place in the intact eye but has never been observed in the isolated retina. In vitamin A deficiency, reaction B or E or both are too slow to keep the supply of visual purple adequate.

The fact that the pigmented epithelium is essential to the visual purple process suggests the possibility that it, like other epithelial structures in times of vitamin A scarcity, may not function normally and thus indirectly also contribute toward visual impairment.

The chemistry and the physiology of vitamin A as revealed in its function as a component of visual purple do not necessarily imply the presence of a photosensitive substance in the more generally affected epithelial cells. However, they do suggest that vitamin A may serve as a prosthetic group in other conjugated proteins. The exact nature of these substances and how they function is one of the most interesting problems in cell physiology.

Vitamin A and Other Body Processes.—In association with vitamin A deficiency no significant deviations from the normal have been found for carbohydrate

Vitamin A and the perception of light.

in the egg, but the value soon returns to a more stable level after the removal of the oil, in spite of the still high reserves in the liver.

Vitamin A and Cell Physiology.—One of the earliest functional changes observable in association with vitamin A deficiency is a decreased ability for dark adaptation, nutritional night blindness which responds to vitamin A therapy. The quantity of visual purple present in the retinas which have been dark adapted for varying periods demonstrates that the resynthesis of visual purple in vitamin A deficient animals is abnormally slow. It is possible also to demonstrate experimentally the correlation between the slow rate of regeneration of visual purple and the delayed dark adaptation.⁴⁷ Faulty twilight vision in vertebrates occurs with vitamin A deficiency because the mechanism for the formation of visual purple in the rod of the retina is defective.

Wald⁴⁸ has recently shown the previously reported high vitamin A value of retinal tissue to be due to vitamin A. He has presented strong evidence that visual purple is a conjugated protein in which vitamin A is a prosthetic group.

The cones of the retina are associated with the perceptions of color and other visual functions which

metabolism, blood chemistry, absorption of fat, carbohydrate and proteins, nitrogen metabolism, and calcium and phosphorus metabolism.⁵¹ Fat metabolism does not seem to be obviously altered, as fat is still absorbed, mobilized, desaturated and oxidized during vitamin A deficiency.⁵²

Repeated attempts have failed to show any deviations of immunologic mechanisms with vitamin A nutrition which were not due to secondary factors, such as inanition and infection.⁵³

PATHOLOGY

The specific pathologic changes of vitamin A deficiency are found in many epithelial structures and may be epitomized as follows: atrophy of the epithelium concerned, reparative proliferation of basal cells, and differentiation of the new product into a stratified keratinizing epithelium. This replacement epithelium, regardless of the previous functions and structure of the region, is identical in all locations and comparable in all its layers with epidermis. Other consequences of vitamin A deficiency are common to other nutritional disturbances, including other vitamin deficiencies.⁵⁴

Epithelial Tissues.—Since the pathognomonic pathologic features of vitamin A deficiency are the consequence of epithelial changes, these will be described in some detail. Replacement by keratinizing epithelium is a late effect and follows a nonviable degree of epithelial atrophy. Reparative proliferation on the part of basal cells follows. In epitheliums of the stratified and transitional types, such as those of the cornea, conjunctiva, bladder, ureter and renal pelvis, the basal cells engaged in reparative proliferation may maintain a continuous layer from the beginning, and hence the process appears to be true metaplasia. In other epitheliums, such as those of ducts of glands, the respiratory mucosa and the uterus, where focally distributed basal cells alone have proliferative power, scattered areas of new cells appear. These groups of new (reparative) cells, by their continued growth, undermine, coalesce, and replace the original epithelium by a stratified keratinizing epithelium. Both in experimental animals and in infants, an atrophic epithelium having the histologic appearances of viability may remain for a period above the replacement epithelium. The latter may consist at first of only one or two layers of flat cells, as if the first effort was to cover surface as rapidly as possible. Continued multiplication of cells results in the epidermis-like tissue and separation of the atrophic original epithelium.

Many of the striking gross pathologic features of the deficiency in man and in animals are the outcome of the accumulation of keratinized epithelial cells in glands and their ducts and in other organs. In glands, cysts of considerable size, filled with yellowish cheesy masses of keratinized cells, are formed. In the lungs of human infants as well as of experimental animals this process leads to occlusion of bronchi, formation and filling of bronchiectatic cavities with keratinized cells, and atelec-

tasis. Early workers regarded such cysts as abscesses, and hence vitamin A was believed to protect against infection.

The plugs of desquamated epithelial cells in ducts, bronchi and trachea, which open on regions normally infected with bacteria, act as a culture medium, yet rarely are the surrounding tissues invaded, presumably because of the protection offered by the stratified epithelium.

*Distribution of the Keratinizing Metaplasia.*⁵⁵—In the rat, the order of response to vitamin A deficiency by keratinizing metaplasia is (1) salivary glands, including the submaxillary, parotid and all accessory glands of the tongue, buccal cavity and pharynx; (2) respiratory tract, including the nares, maxillary sinuses, Jacobson's organ, trachea and bronchi; (3) genito-urinary tract, including the renal pelves, ureters, bladder, epididymis, prostate, seminal vesicles, coagulating glands, uterus, oviducts and accessory sex glands of the vulva, and (4) eyes and parocular glands, including the corneal and palpebral conjunctiva, the harderian, intra-orbital and extra-orbital lacrimal glands and the meibomian glands.

In the guinea pig, lesions of the conjunctiva and parocular glands did not develop in our experiments⁵⁶ even though advanced lesions (keratinizing metaplasia and its consequences) were found in all the other locations recorded for the rat. This we now know to have been due to the vitamin A in the orange juice used to prevent vitamin C deficiency. If cevitamic acid is employed for this purpose, the eyes respond late in the course of vitamin A deficiency, though less conspicuously than in rats. Early and extraordinary degrees of metaplasia as compared with this condition in the rat take place in the uterus and bladder of guinea pigs. In both rats and guinea pigs, permanent keratinizing of the vaginal epithelium takes place.

Mason⁵⁷ has studied in detail the consequences of vitamin A deficiency on the genital organs of rats. Atrophy of the testes in the male, noted by Wolbach and Howe,⁵⁸ was proved to be constant in animals with vitamin A deficiency even with an adequate supply of vitamin E.⁵⁹ In females⁶⁰ no injury of the ova, impairment of implantation or disturbances of endocrine function of ovary and anterior hypophysis could be shown. Retardation of growth and death of fetuses due to placental injury were found. Prolonged gestation due to decreased vitality and death of fetuses and difficult parturition with excessive uterine bleeding were other consequences. Resorption of fetal sites occurred with marked deficiencies. The effect on the fetus was shown to be due to placental injury in con-

trast to vitamin E deficiency when the primary effect is on fetal tissues.

In human infants⁶¹ keratinizing metaplasia has been found in the conjunctiva, cornea, mucosa of the nares, accessory sinuses, including the maxillary antrums, trachea, bronchi, pancreas, renal pelvis, ureters, salivary glands, uterus and periurethral glands. The commonest and earliest appearance of the metaplasia is in the trachea and the bronchi. Next in frequency is its appearance in the pelvis of the kidney. The early effect of the deficiency on the respiratory mucosa is a satisfactory explanation of the frequency, severity and persistence of the pneumonia that has been responsible in most instances for the death of infants deficient in vitamin A.⁶²

The Eyes.—In the human being, as in experimental animals, involvement of the eye occurs late. The earliest demonstrable change is metaplasia of the epithelium of the conjunctiva and the cornea. Atrophy and metaplasia (of ducts) of the lacrimal glands contribute to the consequences of the accumulation of keratinized cells in the conjunctival sac. The cornea becomes vascularized, edematous and infiltrated with leukocytes. Necrosis of the cornea may occur beneath intact hyperkeratotic epithelium. Infection of the cornea, favored by the accumulation of keratinized cells, may lead to ulceration and hypopyon.

The Teeth.—Owing to atrophy and metaplasia of the enamel-forming organ, the continuously growing incisors of rats and guinea pigs are profoundly affected. After atrophy of the enamel-forming organ there are atrophy and cessation or depression of the functioning of odontoblasts. The formation of enamel stops, and striking deformities of the tooth take place because of diminished and defective formation of dentin.⁶³

By keeping rats for long periods in a state of incomplete vitamin A deficiency, Orten, Burn and Smith⁶⁴ have produced tumor-like formations and tooth duplications at the formative end of the incisors, understandable because of the effect of deficiency on the enamel-forming epithelium. Boyle⁶⁵ has described in the tooth germ of an infant with vitamin A deficiency changes in the enamel organ comparable to those occurring in rodent incisors. May Mellanby⁶⁶ has summarized her work on teeth in an excellent review and presents evidence that absent or defective enamel and dentin formation are consequences of vitamin A deficiency. Recently May Mellanby and King,⁶⁷ presumably on the basis of Edward Mellanby's neurologic observations on vitamin A deficiency, expressed the thought that "loss of neurotrophic control owing to vitamin A deficiency may be partly responsible for pyorrhoea and other diseases of the periodontal tissues and even of dental caries." In all probability, vitamin A deficiency during the formative period of teeth outranks in the human being all other vitamin deficiencies in importance.

The Respiratory Tract.—The consequences of vitamin A deficiency on the respiratory tract can be inferred from the fact that the respiratory mucosa in all locations undergoes keratinizing metaplasia. As atrophy precedes the replacement, clinical effects of the deficiency in all probability occur long before keratinizing epithelium makes its appearance. Death due to pneumonia is common in infants.⁶² The pneumonia is usually of the interstitial or peribronchitis type. Regions of atelectasis due to plugging of bronchioles by keratinized cells and bronchiectasis due to cystic dilatation of bronchi from the same cause are gross features of the lungs. The lusterless opaque lining of keratinized cells may be apparent in larger bronchi and tracheas. In the accessory sinuses and nares and probably in the eustachian tubes are other regions where consequences of vitamin A deficiency are obvious.

The Skin.—No noteworthy consequence of vitamin A deficiency in the skin of experimental animals has been described. In Blackfan and Wolbach's cases⁶⁸ no cutaneous condition was noted that could be attributed solely to the deficiency. Dryness and scaliness of the skin have been noted, as in malnutrition of diverse causes in infants.

In sexually mature persons, cutaneous lesions associated with vitamin A deficiency and analogous to those occurring in other epithelial structures have been reported by several authors, chiefly from China, but also from South Africa, England and America. The skin becomes dry and rough and then a papular eruption appears. The papules are formed by hyperkeratosis of the hair follicles. Atrophy of sweat glands and keratinizing metaplasia of their ducts are responsible for absence of sweat. Sebaceous glands atrophy and undergo keratinizing metaplasia. The order of appearance and distribution of the papules due to hyperkeratosis of hair follicles is the anterolateral aspect of the thighs and the posterolateral aspect of the upper part of the forearms, extensor surface of the arms and legs, shoulders, abdomen, back, buttocks, the fore part of the neck and the back of the neck. There is a general increase in the pigmentation of the skin and conjunctivae, although in the hyperkeratotic hair follicles and immediately adjacent epidermis the pigment is decreased. Mu, Frazier and Pillat⁶⁹ have demonstrated an increase both of melanin-building pigments and of melanin in the darkened skin and conjunctivae. The best clinical and pathologic descriptions and the complete bibliography are to be found in a recent paper by Frazier and Hu,⁷⁰ the first to describe this condition.

The Stomach and Intestine.—Hyperkeratosis with ulceration in the forestomach of rats as a consequence of vitamin A deficiency has frequently been reported. This part of the stomach of the rat is normally lined with stratified squamous epithelium. While hyperkeratosis is of frequent occurrence (we have seen and studied these lesions), it cannot be regarded as specific. Pappenheimer and Larimore,⁷¹ who were the first to describe such lesions, excluded vitamin deficiency as

a factor. Fuzimaki has reported on unsatisfactory evidence the development of the gastric lesions into carcinoma. That vitamin A deficiency and carcinogenesis are not related has been shown by Sugiura and Benedict.⁷²

Lesions of the stomach and intestine in association with vitamin A deficiency are of rare occurrence in man and in experimental animals and, beyond slight degrees of atrophy of the mucosa, are probably not related specifically to the deficiency. The esophagus in man⁷³ and animals responds by hyperkeratinization. References to gastro-intestinal disturbances in man caused by vitamin A deficiency are given by Robertson.⁴

Genito-Urinary Tract.—In rats complete obstruction of the ureters and renal pelvis due to accumulation of keratinized cells may be the cause of death. In human infants⁶⁸ less marked degrees of this change are common and may be grossly recognizable post mortem. The formation of calculi in vitamin A deficient rats is probably dependent on an additional factor, as calculi are of extremely rare occurrence in our experience. Keratinization in the urinary bladder occurs in man as well as in laboratory animals. Atrophy of the testes and keratinizing metaplasia of the uterine mucosa may be expected in human adults.

The Nervous System.—Signs suggestive of nerve lesions in human beings with vitamin A deficiency have not been reported. The experience of investigators has varied in regard to the occurrence of paralysis and other signs of nervous lesions in experimental animals. Hughes, Aubel and Lienhardt⁷⁴ in 1928 described extreme incoordination and spasms in swine and found degeneration of myelin sheaths in the spinal cord and in the optic, sciatic and femoral nerves. The same writers⁷⁵ also recorded similar signs and lesions in fowls and cattle. In neither report were the affected nerve fibers identified as motor or sensory. Edward Mellanby⁷⁶ in 1931 reported incoordination, spasticity and paralysis in dogs nurtured on diets containing much cereal and no vitamin A. Degeneration of myelin sheaths in the spinal cord, particularly in the sensory tracts, was reported.

Seifried⁷⁷ in 1932 described ataxia, incoordination and convulsions in fowls. He found degeneration in anterior horn cells of the cord, in ganglion cells of the motor cortex, the nucleus dentatus and nuclei of the medulla, and in the Purkinje cells of the cerebellum. Demyelination was found in the spinal cord and in the sciatic, brachial and optic nerves. It is to be noted that motor nerve cells were largely involved.

Zimmerman⁷⁸ in 1933 described paralysis in rats after very short periods on a vitamin A deficient diet, the majority showing paralysis within forty days. Degeneration of myelin sheaths was found in the brachial plexus and the sciatic nerves but not in the optic nerves. In the spinal cord the lesions were in the sensory tracts and in the crossed and direct pyramidal tracts. Details of the experiment and an

account of the signs exhibited by these animals were subsequently reported by Aberle.⁷⁹

Edward Mellanby⁸⁰ in 1934 recorded degeneration of cells of the gasserian ganglion and myelin degeneration of the ophthalmic division of the fifth nerve in rabbits, a dog and rats. He stated, though without presenting his evidence, that degeneration of the afferent nerves is widespread with vitamin A deficiency. The importance of Mellanby's paper lies in his speculation that the epithelial changes of vitamin A deficiency are secondary to loss of neurotrophic control. Similar speculations by May Mellanby⁶⁷ in regard to the pathology of teeth have been mentioned. Setterfield and Sutton⁸¹ in 1935 reported degeneration of myelin sheaths in the sciatic and femoral nerves in white rats and claimed superiority for their technic using polarized light on frozen sections of nerves fixed in solution of formaldehyde. Zimmerman and Cowgill⁸² confirmed Zimmerman's⁷⁸ and Aberle's⁷⁹ work and stated that carotene added to the diet prevents the nerve lesions. Carotene, however, did not restore function to the nervous system, even though other evidences of A deficiency were cured. This was attributed to the permanent nature of the nerve lesions.

Failure to observe signs of nerve lesions or to find degeneration of myelin sheaths in vitamin A deficient animals are recorded by an impressive number of workers. Duncan⁸³ in 1931 reported: "No consistent differences were observed in nerves from animals on diets low in vitamin A or E when compared to nerves from rats of the same age" and "the nerves from healthy well nourished rats exhibited changes equal to those in rats extremely emaciated and paralyzed from the effects of feeding on a diet low in vitamin B." Suzman, Muller and Ungley⁸⁴ found no nervous lesions in adult dogs on a diet deficient in vitamin A. Grinker and Kandel⁸⁵ failed to observe nervous symptoms in monkeys fed on a vitamin A deficient diet and found no degenerative lesions of myelin sheaths in the central nervous system. Arthur Weil of Chicago and Charles Davison of New York, in the discussion of Grinker and Kandel's paper, reported failures to find nerve lesions in rats in experiments with vitamin A deficiency.

Radhakrishna Rao,⁸⁶ in studies with rabbits, rats and fowls, although often finding myelin degeneration in the afferent nerves of the eye, failed to correlate the degeneration with the onset and course of the ocular lesions. Repair of the corneal lesions following administration of vitamin A took place without recovery of the nerve lesions. He concluded that "there is no evidence to suggest that xerophthalmia is secondary to

a loss of the neurotrophic control of the ophthalmic division of the trigeminal nerve."

Eveleth and Biester⁸⁷ maintained that "neither vitamins A nor B complex are responsible for the myelin degeneration of the spinal cords and peripheral nerves in swine."

Wolbach and Howe⁸⁸ in 1925 stated: "As the rats exhibited no symptoms pointing to lesions of the nervous system, the peripheral nerves were not studied. No lesions were found in brain, cerebellum and sympathetic ganglia." Marchi preparations were not made. A review of their records show that a few rats, shortly before death, showed extreme muscular weakness and did drag their hind legs. This was attributed to extreme degeneration of the muscles. In work now in progress under a grant from the Milton Fund to the Harvard Dental School, in which diets devised by Otto Bessey are being used, signs of nerve lesions do not appear in rats and guinea pigs. Studies of the nervous system made by R. L. Swank⁸⁹ with his very reliable modification of the Marchi technic failed to show degeneration of myelin in the spinal cord or peripheral nerves in rats and guinea pigs which had exhibited extreme keratinizing metaplasia of epitheliums.

There is no substantial evidence that degeneration of myelin sheaths is a specific consequence of vitamin A deficiency. That it does occur in some strains of laboratory animals cannot be denied. The relation of degeneration of skeletal muscle to the signs regarded as of nervous origin is a problem having a bearing on the subject. Severe degeneration of muscle is common in association with vitamin A deficiency in man, guinea pigs and rats.⁸⁹

We have observed degeneration of skeletal muscles in guinea pigs deficient in vitamin C and in rats deficient in vitamin B₂ complex. Goettsch and Pappenheimer⁹⁰ have described a "progressive highly selective and ultimately fatal dystrophy of the voluntary muscles" in guinea pigs and rabbits on diets with adequate vitamin content. No significant lesions were found in the spinal cord and peripheral nerves. The same authors, with Rogers,⁹¹ could find no alterations of the motor nerve terminals in muscle. It is not clear whether Marchi preparations were employed, as emphasis was placed on silver impregnation methods. These papers by Pappenheimer and his associates are pertinent to the present discussion because they indicate the possibility of ascribing to nerve lesions behavior of laboratory animals caused by muscle degeneration.

Since degeneration of myelin sheaths is not a constant accompaniment of vitamin A deficiency, as is epithelial metaplasia, it is not necessary to present the many objections to Mellanby's thesis that loss of nerve function may be the cause of the epithelial changes which are invariably the consequence of vitamin A deficiency regardless of species.

Other consequences of vitamin A deficiency, which are not specific, are (1) inability to store fat, (2)

hemosiderosis apparently due to anemia, (3) cessation of growth of bones, (4) the degenerative lesions of skeletal muscles already mentioned and (5) lymphoid hypoplasia of the spleen.

Loss of fat occurs in spite of an abundant supply, but this takes place with other vitamin deficiencies, notably deficiency of the B₂ complex. The anemia in infants and experimental animals is accompanied by hemosiderosis in the spleen and liver and, finally, by atrophy of the spleen and bone marrow. In animals, restoration of vitamin A to the diet causes regeneration of bone marrow, disappearance of hemosiderin from the spleen and liver and, in the rat and the guinea pig, active hyperplasia of the spleen and an outburst of erythroblastic activity. The anemia and hemosiderosis also occur with B₂ complex deficiency and with prolonged partial vitamin C deficiency.

The effect of vitamin A deficiency on growth of bone is complete cessation of endochondral bone formation, indistinguishable from that occurring in any long-continued state of malnutrition.

While Mason⁹² has studied some of the consequences of vitamin A deficiency in the rat on gestation and parturition, the importance of further research is indicated by the brief publication of Hale⁹³ recording in the offspring of vitamin A deficient swine various congenital defects, including defective eyes, absence of eyes, misplaced kidneys, harelip, cleft palate and extra earlike growths.

Excessive administration of vitamin A concentrates to experimental animals has been reported to result in damage to bone, kidneys, skin and other soft tissue. However, conclusive evidence awaits a preparation of pure material. No injury is likely by use of the usual liver oils even in high dosage. Large doses of carotene given orally or by injection are innocuous.⁹³

Repair in Recovery from Vitamin A Deficiency.—Repair after restoration of vitamin A to the diet is rapid. In rats there is a lag of a few days, but within six to eight days gain in weight, resumption of growth in bones and teeth, and regeneration of bone marrow and spleen are apparent. Reparative changes in the metaplastic epithelium begin as early as the fifth day.⁶⁹ The initial changes are separation of superficial keratinized cells and vacuolization of cells of intermediate layers. The epithelium becomes divided into two zones in consequence of progress of vacuolar degeneration and leukocytic infiltration. All those cells, apparently irreversibly differentiated toward keratinization, undergo degeneration; the deep zone, corresponding to the stratum germinativum of epidermis, survives, and the cells proceed to differentiate into the type of epithelium originally present. On the whole the change is an abrupt one and affords further evidence that the epithelial changes of vitamin A deficiency are primary and not of nervous origin, particularly as Zimmerman and Cowgill⁸² failed to restore function to the nervous system by administering carotene, while all other manifestations of the consequences of their vitamin A deficient diet were cured.

The changes in the repair of epitheliums after vitamin A deficiency have their normal counterpart in changes in the vagina of rodents during the part of the estrous cycle in which the cornified vaginal epithelium returns to the mucous type.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION
OF THE FOLLOWING REPORTS. HOWARD A. CARTER, Secretary.

GODSEND HEARING AID NOT ACCEPTABLE

Manufacturer: Godsend Hearing Aid Company, 4204 Davis Lane, Cincinnati.

The Godsend Hearing Aid consists of the following parts: (1) a microphone transmitter of the carbon ball type housed in a brown molded bakelite case, weight 59 Gm.; (2) a magnetic midget type air conduction receiver of the direct current excitation type, weight 10 Gm.; (3) a bone oscillator in a laminated bakelite case with spring head band, weight 28 Gm.; (4) a carbon particle amplifier housed in a bakelite case containing a current varying rheostat, the housing fitted with pins for plugging directly into a battery jack, weight 60 Gm., and (5) a bakelite battery case accommodating three ordinary flashlight cells, weight 56 Gm. without battery. In addition, there are the usual connecting cords.

The unit was investigated by a consultant appointed by the Council. He pointed out certain faults in the mechanical construction and performance of the hearing aid. The design of the microphone transmitter is clumsy and bulky; the rheostat arm mounted in the amplifier case is made of thin sheet metal, easily deformed by accident and uncertain in operation. This frail lever might easily be rendered inoperative in any position as the result of pressure of the clothes. In the model submitted, the arm did not make contact over the middle range of the rheostat. Also the air conduction receiver is faulty in that the ear piece (which does not conform to the contours of the ear but merely terminates in a bulb) fits rather loosely in the receiver, so that the two may fall apart.

Performance tests showed that the current drain of the Godsend Hearing Aid was exceptionally high. Thus, with three new cells delivering 4.5 volts at the terminals, the set with rheostat full on draws more than 220 milliamperes; even when only two cells are used with 3 volts the drain is more than 140 milliamperes. The high current drain resulted in the very rapid exhaustion of the three flashlight cell battery furnished with the instrument. Consequently the tests for amplification and intelligibility were conducted with large dry cells capable of maintaining their terminal voltages constant under the large current drain. It was further observed that the hearing aid was unstable, owing to self oscillation, when operated with three new dry cells and the rheostat full on.

Intelligibility and loudness gain tests were performed. For the apparatus in question, it was found that increasing the loudness by moving the rheostat arm toward the full-on position resulted in a severe loss of intelligibility. Indeed, even when the battery current was cut down to 60 milliamperes as against a maximum value of 220 the intelligibility was not greater than 80 per cent. With this low setting it is very difficult to transmit single unfamiliar names over the instrument and its rating for this purpose is not greater than 30 per cent. The loudness gain, moreover, for this setting is approximately 8 decibels (average of four observers). The largest loudness gain observed was for maximum rheostat setting and averaged 23 decibels, but under these circumstances the intelligibility was practically zero; certainly the instrument was unusable.

When the apparatus was examined for bone conduction oscillation, similar results were obtained.

Exaggerated and misleading claims are made in the advertising matter. These claims, as noted later, suggest that the ideal hearing aid has been found. This is certainly incompatible with facts in the hearing aid research. Excerpts from a pamphlet entitled "Joyful News for the Deaf" follow: "Great happiness awaits you," "the principle of the Godsend Hearing Aid has turned a silent, cold, lonely world into a paradise," "restores normal hearing," "easier to adjust and take on and off than a pair of gloves," "you may obtain instant relief from

deafness," "most improved type of hearing aid which leading ear specialists approve and recommend," "ready to bring you good hearing immediately after you take it out of the box" and "open the door to the happiness that normal hearing can bring you."

A leaflet, "Here's Sensational, History-Making News," contains the same type of exaggerated claims. Quotations follow: "Now, even those who have considered themselves hopelessly deaf—totally cut off from the world of conversation . . . may HEAR again," "overcome the obstacle of advanced hearing defect" and "it is possible to hear . . . where even people with normal hearing must frequently strain to understand."

The name "Godsend Hearing Aid" is compatible with the firm's grandiose claims, but the Council does not consider the name an appropriate one for an instrument of this sort.

In view of the foregoing report, the Council on Physical Therapy voted not to accept the Godsend Hearing Aid for inclusion in its list of accepted devices, since it is an inferior instrument, faulty in mechanical construction and a poor acoustic amplifier. It is apt to be of little, if any, use to a person with defective hearing. In addition, the advertising matter contains many exaggerated or misleading claims, as aforementioned.

ELECTRO-EAR AND ROSETTE MODEL HEARING AIDS NOT ACCEPTABLE

Manufacturer: American Earphone Company, 10 East Forty-Third Street, New York.

The Electro-Ear and the Rosette Model of the Electro-Ear are battery operated hearing aids. The Electro-Ear consists of two parts, an earpiece fitting directly into the ear and a small case with self-contained microphone and battery. Either two or three ordinary flashlight batteries supply the current, 3 or 4½ volts. A slide switch on top of the case provides volume control.

In the Rosette Model the microphone and transmitter are separate. This model is available for air conduction with or without mechanical amplification and amplified bone conduction. The mechanical amplifier fits on top of the battery. Single or double transmitters may be employed. Current may be supplied by 3 or 4½ volt batteries.

The discrete sentence intelligibility test was adopted by the Council as being the most suitable method of determining the usefulness of a carbon microphone hearing aid. This test gives an index or figure of merit which permits comparison between various instruments and at the same time rates or scales them in relation to a theoretically perfect instrument.

Briefly, the intelligibility test is conducted as follows: A number of relatively short and simple statements (usually 100) are read before the microphone of the hearing aid and the listener repeats each sentence as he hears it. If he interprets 90 per cent of 100 statements correctly, the hearing aid is given a 90 per cent intelligibility rating. Obviously, the rating will vary with several factors unrelated to the hearing aid, such as the type and degree of the hearing loss of the individual using the instrument, the voice quality of the speaker, the distance of the speaker from the microphone, and the acoustic properties of the room in which the speaker and microphone are located.

In the testing of these instruments, the investigator's voice was used throughout with the normal conversational tone and loudness, the mouth being six feet distant from the microphone. The speaker was in one room with the microphone, and the listener in an adjacent room. A piece of metal tubing about three inches in diameter and a foot in length extended through the brick wall of one room into the other. The cords of the microphones were wrapped in felt and run through this tubing, which was then packed tight with felt to minimize the loudness of the speaker's voice in the listener's room. A high quality microphone was also placed in the listener's room and connected through the pipe to an amplifier and reproducer before the speaker so the responses of the listener could be determined. Two normal and two hard-of-hearing persons

cooperated in the testing. The normal persons could just hear the speaker's voice but not sufficiently well to understand any of the sentences without the assistance of one of the aids. The speaker adjusted the setting of the volume controls on the microphones of the hearing aids to the intensity level preferred by each person, determined by practice sentences.

In the accompanying table, listeners W and X had normal hearing, Y had an approximately uniform hearing loss of 30 decibels from 64 to 8,192 cycles, and Z had a uniform loss of approximately 45 decibels over the same frequency range. Y had normal bone conduction, while the bone conduction of Z was slightly below normal.

Hearing aid I is the Electro-Ear instrument with small battery contained within the microphone case. Hearing aid IIA is the Rosette model employing air conduction without the amplifier attached; IIB is the same instrument with the amplifier, and IIC is the same unit equipped for amplified bone conduction, these being the various ways to assemble or hook up the components of the Rosette model. It was necessary to use the mechanical amplifier (the accessory fitting on top of the battery) with the bone conduction receiver in order to obtain maximum volume.

These data compare favorably with the results obtained from the same listeners with three other well known makes of hearing aids, each tested with amplified air and bone conduction, the medium pitched receivers being used when a choice was available.

Results (Stated in Percentage of Intelligibility)

	I	IIA	IIB	IIC
W (normal).....	93%	90	88	85
X (normal).....	90	91	86	83
Y (30 db. loss).....	91	87	86	84
Z (45 db. loss).....	*	*	83	79

* This person's loss was too great to obtain much value with unamplified air conduction under the test conditions.

Some hard-of-hearing persons cannot obtain worthwhile benefit from any type of portable hearing aid. If the performance of these instruments is unsatisfactory, the firm states in its advertising matter that the purchase price will be refunded, less a small fee for trial (coverage).

The instruments look durable but each of the models has a possible weakness. In the Electro-Ear the cord from the case to the earpiece may be protected against wear and friction by a rubber grommet or some such protective device at the point where the cord passes out through the case. It also seems that the resistance wire of the volume control of the Rosette Model should be enclosed so that it would not be exposed to dirt and dust.

The advertising matter put out with these units contains objectionable or misleading statements. One piece, "All Modern Hearing Devices," states that these instruments are "individually suited to every degree of deafness." This statement should be deleted or evidence submitted to support it. It is noted that several hearing devices are advertised which have not been submitted to the Council for consideration, notably "Twin-Fone," "Super-Ear" and "Vibratube."

In view of the foregoing report, the Council on Physical Therapy voted not to accept the Electro-Ear and Rosette Model of the Electro-Ear hearing aids for inclusion in its list of accepted devices because the advertising matter contains misleading or objectionable statements and, further, each unit has certain deficiencies in construction as pointed out in this report. In addition, the Council believes that these units will be of benefit only to persons with slight impairment in hearing.

The foregoing report was submitted to the firm with a statement to the effect that the Council would reconsider the unit without prejudice, provided the firm improved the construction of the hearing aid and revised the advertising matter.

Ample time was given the firm to submit the improved models and the revised advertising. The new equipment and revised advertising matter have not been received.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

EPHEDRINE SULFATE-LILLY (See New and Non-official Remedies, 1938, p. 228).

The following dosage form has been accepted:

Ampoules Ephedrine Sulfate-Lilly, 1 cc., 0.025 Gm. ($\frac{3}{8}$ grain).

ANTIPNEUMOCOCCUS SERUM TYPES IV AND VIII COMBINED.—An antiserum containing antibodies of both types IV and VIII pneumococci (*Diplococci pneumoniae*).

Dosage.—Intravenously, first dose, 10,000 units of each type, followed by a second dose of from 20,000 to 40,000 units of each type one and one-half hours later; when indicated, the second dose may be repeated at two hour intervals.

Lederle Laboratories, Inc., Pearl River, N. Y.

Antipneumococcus Serum, Types IV and VIII, Refined and Concentrated.—Prepared by immunizing horses with intravenous injections of cultures of type IV and type VIII pneumococci. When test bleedings show the serum to have reached a sufficient degree of potency the horses are bled aseptically and the serum refined and concentrated by means of the ethyl alcohol precipitation method described by Lloyd D. Felton (*J. Immunol.*, November 1931, p. 347). The usual sterility tests prescribed by the National Institute of Health are carried out and safety tests are made by injection into white mice and guinea pigs. The potency tests are based on the method described by Lloyd D. Felton (*J. Infect. Dis.*, December 1928, p. 531). The potency of the preparation is expressed in terms of the unit developed by Felton (*Boston M. & S. J.*, May 15, 1924, p. 819; *J. Infect. Dis.*, September 1925, p. 199, October 1925, p. 309) and used by Park. The unit is based on the smallest amount of antibody that will protect against one million fatal doses of virulent type IV and VIII culture. In actual laboratory practice a carefully standardized control serum is used in each test as a basis of comparison. The procedure for the mouse protection potency test for both type IV and VIII antibody is exactly similar to that described for type I antibody (*J. Immunol.*, July 1932, p. 91). Marketed in packages of one vial containing 10,000 units each of types IV and VIII and in packages of one vial containing 20,000 units each of types IV and VIII. Each package contains a vial of normal horse serum (1:10 dilution) for the conjunctival test.

ANTIPNEUMOCOCCUS SERUM TYPES V AND VII COMBINED.—An antiserum containing antibodies of both types V and VII pneumococci (*Diplococci pneumoniae*).

Dosage.—Intravenously, first dose, 10,000 units of each type, followed by a second dose of from 20,000 to 40,000 units of each type one and one-half hours later; when indicated, the second dose may be repeated at two hour intervals.

Lederle Laboratories, Inc., Pearl River, N. Y.

Antipneumococcus Serum, Types V and VII, Refined and Concentrated.—Prepared by immunizing horses with intravenous injections of cultures of type V and type VII pneumococci. When test bleedings show the serum to have reached a sufficient degree of potency the horses are bled aseptically and the serum refined and concentrated by means of the ethyl alcohol precipitation method described by Lloyd D. Felton (*J. Immunol.*, November 1931, p. 347). The usual sterility tests prescribed by the National Institute of Health are carried out and safety tests are made by injection into white mice and guinea pigs. The potency tests are based on the method described by Lloyd D. Felton (*J. Infect. Dis.*, December 1928, p. 531). The potency of the preparation is expressed in terms of the unit developed by Felton (*Boston M. & S. J.*, May 15, 1924, p. 819; *J. Infect. Dis.*, September 1925, p. 199, October 1925, p. 309) and used by Park. The unit is based on the smallest amount of antibody that will protect against one million fatal doses of virulent type V and VII culture. In actual laboratory practice a carefully standardized control serum is used in each test as a basis of comparison. The procedure for the mouse protection potency test for both type V and VII antibody is exactly similar to that described for type I antibody (*J. Immunol.*, July 1932, p. 91). Marketed in packages of one vial and in packages of one syringe containing 10,000 units each of types V and VII; also in packages of one vial and in packages of one syringe containing 20,000 units each of types V and VII. Each package contains a vial of normal horse serum (1:10 dilution) for the conjunctival test.

PHENOBARBITAL SODIUM-ABBOTT (See New and Nonofficial Remedies, 1938, p. 125).

The following dosage form has been accepted:
Tablets Phenobarbital Sodium-Abbott, 1 grain.

RINGER'S SOLUTION (See New and Nonofficial Remedies, 1938, p. 357).

Ringer's Solution. Each 100 cc. contains sodium chloride 0.7 Gm., potassium chloride 0.03 Gm. and calcium chloride 0.025 Gm. Marketed in bottles of 500 and 1,000 cc.

Prepared by the Abbott Laboratories, North Chicago, Ill.

SULFANILAMIDE (See New and Nonofficial Remedies, 1938, p. 450).

Pulcoids Sulfanilamide, 5 grains.
Prepared by the Drug Products Company, Inc., New York. No U. S. patent or trademark.

Sulfanilamide Tablets, 5 grains.
Prepared by Sharp & Dohme, Philadelphia and Baltimore. No U. S. patent or trademark.

DEXTROSE (See New and Nonofficial Remedies, 1938, p. 162).

The following dosage form has been accepted:

The Abbott Laboratories, North Chicago, Ill.

Dextrose 10% in Ringer's Solution: Each 100 cc. contains dextrose, U. S. P., 10 Gm., sodium chloride 0.7 Gm., potassium chloride 0.03 Gm. and calcium chloride 0.025 Gm. Supplied in bottles containing 500 and 1,000 cc.

VIOSTEROL IN OIL (See New and Nonofficial Remedies, 1938, p. 482).

Viosterol (A. R. P. I. Process) in Oil-Lederle.—A brand of viosterol in oil-N. N. R.

Manufactured by the American Research Products, Inc., a division of General Mills, Inc., Minneapolis, under license agreement with E. I. du Pont de Nemours Co. (Lederle Laboratories, distributor). U. S. patent applied for.

Viosterol (A. R. P. I. Process) in oil-Lederle is prepared by activation of ergosterol through the action of low speed electrons by suitable controlled electrical means. The activated ergosterol is dissolved in bland vegetable oil biologically assayed and adjusted to have the potency of viosterol in oil-N. N. R.

Council on Foods

ACCEPTED FOODS

THE FOLLOWING PRODUCTS HAVE BEEN ACCEPTED BY THE COUNCIL ON FOODS OF THE AMERICAN MEDICAL ASSOCIATION AND WILL BE LISTED IN THE BOOK OF ACCEPTED FOODS TO BE PUBLISHED.

FRANKLIN C. BING, Secretary.

H & H BRAND PURE PRUNE JAM

Manufacturer.—Max Ams, Incorporated, New York.

Description.—Prune preserve made from dried prunes and cane sugar.

Manufacture.—Selected sun-dried California prunes are subjected to steam in a pressure cooker to soften them, pitted and cooked with 15 per cent solution of cane sugar. The jars are filled with the mixture at 88 C.

Analysis (submitted by manufacturer).—Moisture 42.1%, total solids 57.9%, soluble solids 56.5%, ash 1.1%, fat (ether extract) 0.2%, protein (N \times 6.25) 1.6%, sucrose 2.9%, reducing sugars as dextrose 37.3%, reducing sugars as invert sugar 38.9%, crude fiber 1.1%, carbohydrates other than crude fiber (by difference) 53.9%.

Calories.—2.24 per gram; 64 per ounce.

BRADWAY CHOCOLATE FLAVORED SYRUP

Manufacturer.—The Bradway Chocolate Company, Inc., New-castle, Ind.

Description.—A beverage base consisting of sucrose, water, tapioca, flour, cocoa and chocolate, salt, artificial flavoring and tartaric acid.

Manufacture.—Cane sugar and water are mixed, constantly agitated while being heated in a steam jacketed copper kettle to 104 C. for twenty minutes to promote inversion and cooled to 88 C. Formula proportions of the remaining ingredients are added. The mixture is stirred, homogenized at 2,500 pounds pressure, filled into five-gallon pails and sealed at 71 C.

Analysis (submitted by manufacturer).—Moisture 19.6%, total solids 80.4%, ash 1.6%, fat (ether extract) 4.7%, protein (N \times 6.25) 2.8%, sucrose 25.4%, reducing sugars as invert sugar 30.9%, crude fiber 0.5%, carbohydrates other than crude fiber (by difference) 70.8%, caffeine* 0.055%, theobromine 0.21%.

Calories.—3.37 per gram; 96 per ounce.

* Calculated from an analysis of cocoa and chocolate.

GLORY WHEAT CREAM FARINA

Manufacturer.—The Teichgraber Milling Company, Gypsum, Kan.

Description.—Purified wheat middlings or endosperm.

Manufacture.—Selected winter wheat is cleaned, scoured, tempered and milled in the usual manner. The purified middlings are separated by the usual process of sifting and aspirating and are automatically packaged and weighed.

Analysis (submitted by manufacturer).—Moisture 12.5%, total solids 87.5%, ash 0.4%, fat (ether extract) 0.8%, protein (N \times 5.7) 12.3%, crude fiber 0.2%, carbohydrates other than crude fiber (by difference) 73.8%.

Calories.—3.52 per gram; 100 per ounce.

NUTRADIET FRESH GREEN BABY LIMA BEANS PACKED IN WATER

Distributor.—The Nutradiet Company, a subsidiary of S & W Fine Foods, Inc., San Francisco.

Description.—Canned green baby lima beans packed in water without added sugar or salt.

Manufacture.—Henderson Bush Lima Beans grown within 2 to 5 miles of the cannery are harvested with vines intact and the beans are removed from the vines at the plant, shelled, cleaned with screens and blowers, graded, blanched, cooled in a spray washer and filled into cans. Water is added. The cans are exhausted, sealed and processed for twenty-five minutes at 121 C. and cooled. No insecticide spray is used on the beans, which are canned in from two to six hours after being harvested.

Analysis (submitted by manufacturer).—Moisture 80.9%, total solids 19.1%, ash 0.7%, fat (ether extract) 0.3%, protein (N \times 6.25) 4.7%, crude fiber 1.0%, carbohydrates other than crude fiber (by difference) 12.4%.

Calories.—0.51 per gram; 14 per ounce.

Claims of Manufacturer.—For use in special diets in which sugar or salt is proscribed or in quantitative diets of calculated composition.

GLORY WHOLE WHEAT

Manufacturer.—The Teichgraber Milling Company, Gypsum, Kan.

Description.—A precooked whole wheat breakfast cereal.

Manufacture.—Selected durum wheat is cleaned, mixed with formula proportions of water and salt and cooked under pressure for about ten minutes. When the desired pressure has been reached, it is suddenly released and the wheat is expelled into a screened bin to allow expansion. The product is then screened and dried to between 7 and 8 per cent of moisture content and packaged in moisture proof cellophane bags.

Analysis (submitted by manufacturer).—Moisture 7.4%, total solids 92.6%, ash 1.7%, fat (ether extract) 1.3%, protein (N \times 5.7) 15.3%, crude fiber 0.8%, carbohydrates other than crude fiber (by difference) 73.5%.

Calories.—3.67 per gram; 104 per ounce.

MRS. PALEY'S BABY FOOD—STRAINED SPINACH

Manufacturer.—Paley-Sachs Food Company, Houston, Texas.

Description.—Canned, cooked sieved spinach, slightly seasoned with salt.

Manufacture.—Fresh spinach is trimmed, inspected, thoroughly washed, precooked for five minutes, strained, filled into glass jars, vacuum sealed and heat processed.

Analysis (submitted by manufacturer).—Moisture 92.0%, total solids 8.0%, ash 1.7%, fat (ether extract) 0.3%, protein (N \times 6.25) 2.1%, reducing sugars as dextrose—trace, sucrose—trace, crude fiber 0.8%, carbohydrates other than crude fiber (by difference) 3.1%, calcium (Ca) 0.1%, phosphorus (P) 0.046%, iron (Fe) 0.003%.

Calories.—0.2 per gram; 6 per ounce.

DEPOSITION OF LIPIDS IN THE LIVER

Investigations have established the essential role of the liver for maintaining the life processes. The clear-cut results of hepatectomy and other experimental procedures leave little doubt that this organ is essential for the normal metabolism of the three so-called proximate principles the proteins, the carbohydrates and the lipids. Of the transformations occurring in the liver both under normal and under pathologic conditions, the alterations in lipid content are most striking. It is relatively simple to produce an increase in the quantity of liver lipids in normal animals by administration of diets containing either a high cholesterol or a high fat content. The ease with which this is produced makes available a ready means of determining experimentally the factors which may influence the deposition of lipids in the liver. The role of choline in this connection has already been discussed in these columns.¹ More recently, experimental evidence has accumulated to suggest the importance of endocrine influence in regulating the quantity of liver lipids.

The development of modern knowledge regarding the role of the anterior pituitary gland in lipid metabolism owes much to the investigations of Burn and Ling,² who demonstrated that the injection of certain extracts of the anterior pituitary gland produces an increased excretion of ketone bodies in rats consuming a fat-rich diet. Subsequent studies have confirmed this observation and have served to emphasize the importance of the anterior pituitary gland in the regulation of the rate of lipid metabolism and in the mobilization of the lipids from the body stores to organs, such as the liver, actively concerned in the utilization of this foodstuff. The detailed investigations of Best and Campbell³ have made available interesting experimental data regarding the factors influencing the deposition of lipids in the liver. The daily injection of suitable extracts of the anterior lobe of the pituitary

produced in rats, guinea pigs and mice a rapid increase in size and a marked fatty infiltration of the liver within a few days of the first injection. The increase in size and weight was due chiefly to deposition of fat and water and was accompanied by a decrease in total body fat and an increased excretion of ketone bodies. Although there was some species variation in the degree of the response to anterior pituitary extract, the results in general were similar. The extent of the fat deposition in the liver is in some instances almost as great as that which can be regularly produced by the other methods; e. g., by feeding fat or cholesterol. However, in contrast to the inhibiting action of choline on the deposition of lipids in the livers of animals ingesting a high fat diet, this nitrogenous base did not prevent the increase in liver fat produced by large doses of the anterior pituitary preparation.

These investigations confirm the numerous reports now available indicating the profound influence of the anterior pituitary gland on the processes of intermediary metabolism. Although the best available extracts are still crude, at least in a chemical sense, clinical administration of such anterior pituitary preparations which undoubtedly contain this fat mobilizing and ketogenic principle have already been made, sometimes in considerable doses. In view of the rapid deposition of lipids produced in the livers of experimental animals by the injections of these extracts, caution should be exercised in employing anterior pituitary therapy in unrestricted quantities in treating human patients until further chemical fractionation has been accomplished.

ARMY MEDICAL MUSEUM AND LIBRARY

Congress has passed the bill authorizing the construction of a new building for the Army Medical Library and Museum. At last the world's mightiest collection of medical literature and one of the largest of medical museums will be given adequate quarters.

Fifty-five years ago¹ a committee of the American Medical Association composed of three of America's greatest medical men made a study of the needs of the Army Medical Museum and Library for a building. The committee was composed of Dr. Samuel D. Gross of Philadelphia, the leading surgeon of his day, Dr. Austin Flint of New York, one of the greatest American diagnosticians, and Dr. Oliver Wendell Holmes of Boston, the "Autocrat of the Breakfast Table." The books of the Surgeon General's Library, as it was then called, were stored in Ford's Theater, the scene of President Lincoln's assassination. The specimens of the Army Medical Museum were likewise in storage, and not even in one place. The library then contained 70,000 volumes and 66,000 pamphlets. The museum had some 20,000 specimens. There were 117 medical

2. Burn, J. H., and Ling, H. W.: J. Physiol. 69:xix (May 31) 1930.

3. Best, C. H., and Campbell, J.: J. Physiol. 86:190 (Feb.) 1936; 92:91 (Feb.) 1938.

1. Minutes of the American Medical Association at Its 34th Annual Session, Held in Cleveland, Ohio, June 5, 6, 7, 8, 1883, J. A. M. A. 1:3 (July 14) 1883.

journals published in the country. The *Index Medicus* was not yet four years old. The *Index Catalogue* had not yet advanced beyond the stage of the *Specimen Fasciculus*. John Shaw Billings had been librarian for eighteen years. Congress, duly impressed with the need for a building, made the necessary appropriation. The present well known red brick building that has housed the Army Medical Library for more than half a century resulted from this action.

Library buildings, particularly those built fifty years ago, had no provisions for expansion. Even the beautiful building of the Library of Congress has been outgrown and additions are now in progress. Under the administration of the Medical Department of the Army, the Army Medical Library and Museum have grown steadily until they are now the largest institutions of their kind in America, and probably in the world. The old building is full to overflowing, and the engineers permit no more books to be placed in the stacks except by removal of old volumes to make way for the new. Every nook and cranny is filled with precious volumes. In the museum too the saturation point is almost reached. The Army Medical Library has grown to a million items. The museum has 60,000 specimens and half a million microscopic slides, besides 67,000 negatives of pathologic material. The library subscribes to 2,000 medical journals. Now it is time for history to repeat itself. The American Medical Association played a great part in obtaining the legislation for the old building and contributed with equal force in obtaining the new. At the hearings of the committee in Congress a representative of the Association officially endorsed the movement by authority of the House of Delegates. Other distinguished medical men gave evidence, and letters from more than a hundred more were presented. The medical profession may congratulate itself on the enactment of the bill to authorize the new building.

But this is not enough. Under our legislative procedure the appropriation called for by the authorization bills must be obtained. The Committee on Appropriations of the Senate and House of Representatives will shortly consider this. If we want the new building built now—and the need is nothing less than urgent—we must let our representatives in both houses of Congress know of our desire. The foundation for the building is already laid: not the foundation of stones and mortar but that of Congressional approval. The Army has done its part—we should do ours. This is the national medical library and museum. The Army Medical Department, which conceived them, has administered them for a century, but always with the full knowledge of all concerned that they are at the service of the whole profession. The Army Medical Library and Museum have been efficiently administered all these years, and to the entire satisfaction of the American medical and allied professions. They should continue under control of the Army Medical Department. The service of the sisters—the library and the

museum—has been the more effective because of their intimate association. Let us uphold the hands of the Surgeon General of the Army in this and, in gratitude for what the Army Medical Library and Museum have done for us, cooperate in every way in securing adequate quarters for our two great scientific institutions. Thus we shall serve well the medical profession of today and of tomorrow.

BRONCHOSPIROMETRY

Before the twentieth annual meeting of the American Association for Thoracic Surgery at Saranac Lake, N. Y., last year, Jacobæus¹ of Stockholm presented a bronchoscopic method for determining the size and function of the lung. The method enables determination of the vital capacity, the reserve air and the residual air of each lung. The oxygen intake and the carbon dioxide output may be determined for a unit of time. Earlier attempts to separate the respired air from each lung were concerned chiefly with animal experiments and were based on the principle advanced by Pflüger in 1870. In his technic a catheter, supplied with a distensible rubber cuff at its distal end, was passed into each of the two main bronchi. The experiment called for a performance of a preliminary tracheotomy and the introduction of cannulas, the breathing being recorded on separate spirometers. For obvious reasons this experiment was not applicable to man. In 1932 Jacobæus conceived the idea of separating the air from each lung with the aid of a bronchoscope. At his suggestion a double bronchoscope was devised, one stem of which with a rubber cuff attached is fixed in one of the main bronchi, the other in the trachea, the latter stem thus conveyed the air from the other lung. The proximal ends of the bronchoscope are connected with a double spirometer whereby the curves are simultaneously recorded from the two lungs separately.

The method is apparently harmless, since no severe accident was recorded among the 300 patients in whom bronchospirrometry was practiced by Jacobæus and Björkman. The cases examined included lung tumors, bronchiectasis and postpneumonic conditions. For tuberculous patients these authors regard a recent hemoptysis as the only contraindication.

Bronchospirrometry, when compared with other physical methods of examination, particularly roentgenologic examination, presents certain definite advantages. Jacobæus cites two cases of artificial pneumothorax to show how enormously the function may vary in spite of the fact that on roentgenologic examination the two lungs did not show great difference and that the one with the worse function proved to be the better aerated. Bronchospirrometric studies in patients on whom a thoracoplasty was performed demonstrated that the operation need not destroy the function of the collapsed

1. Jacobæus, H. C.: Bronchospirrometry: A Review of Present Experiences and Some Further Investigations, *J. Thoracic Surg.* 7: 235 (Feb.) 1938.

lung forever and that a certain amount of return of the function may take place. The method likewise demonstrated that the healthy lung in thoracoplasty diminishes in volume because of the displacement of the mediastinum.

Jacobæus made the interesting observation that it is the healthy lung that brings about the violent expiration which constitutes the cough. The affected lung takes little or no share in coughing. In other words, the lung that is most in need of emptying its secretion has the least chance to do so. The sputum in such cases must first pass the bifurcation before being brought up by coughing.

The method appears to be particularly valuable in cases in which there is a question of operative intervention for bilateral lesions. It permits determination of the function of a lung and the indications and contra-indications for operation.

Current Comment

SOURCE OF TYPHOID IN CITIES

In a case of typhoid recently reported in San Francisco it was determined that the patient had crossed the country from Boston by motor, beginning this journey exactly sixteen days before the onset of symptoms in San Francisco. The health commissioner of San Francisco wrote promptly to health departments in Massachusetts, New York, Indiana, Illinois, Ohio, Iowa, Nebraska, Wyoming, Utah, Nevada and California, outlining the trip which the patient had taken. Information was received from Indiana that several cases of typhoid had been traced to the place where the California patient had eaten a meal. Information was received from the board of health in Chicago stating that six cases of typhoid had been reported to the board in persons who had traveled on the bus lines between Chicago and the East. Typhoid therefore can become rapidly and widely disseminated today from a small focus because of new methods of transportation.

PNEUMOCONIOSIS AND PULMONARY CARCINOMA

Contrary to widespread clinical belief, industrial dust does not appear to be an etiologic factor in pulmonary carcinoma unless such dust contains recognized carcinogenic substances, such as radium or tar. In order to test the correlation between inhaled dust and primary neoplasm of the lungs, Vorwald and Karr¹ of the Trudeau Foundation, Saranac Lake, N. Y., assembled all available roentgenographic data. Of the 57,000 cases thus far reported, roentgenologic evidence suggested primary pulmonary tumor in but three, an incidence of 0.005 per cent. Of 1,357 cases of silicosis studied in their own laboratory, but one case of pulmonary tumor was diagnosed. Of their 14,230 cases in which silicosis was not present, only two presumptive pulmonary tumors were noted. The general

impression from this statistical evidence is that the incidence of pulmonary tumor is perhaps even lower in pneumoconiotic persons than that reported in routine necropsies of the general population. This roentgenologic evidence was supplemented by detailed necropsies from 3,739 cases collected from the world literature and 178 from their own laboratories. There were but thirty-two cases in the combined series showing primary malignant changes in the lungs. This suggests an average incidence of about 0.8 per cent. The statistical evidence was further supplemented by a study of 3,338 laboratory animals exposed for periods varying from a few months to three years to heavy concentrations of industrial dusts. Guinea pigs, rabbits, chickens, mice and rats were used in these tests. Fourteen different types of industrial dust were tried. Of special interest were forty mice of a known carcinoma-susceptible strain. At necropsy only two pneumoconiotic animals (guinea pigs) showed the presence of pulmonary neoplasm. In both cases the lesions were interpreted as benign adenomas. The authors conclude that inhaled dusts, except those containing recognized carcinogenic substances (e. g., radium or tar) cannot be considered as etiologic factors in the development of primary carcinoma of the lungs.

BIOCHEMICAL METASTASIS IN TUBERCULOSIS

Among the more recent discoveries of immunology no fact is of greater clinical interest than the observation that local tissue specificity is altered in many local pathologic conditions and that the locally formed biochemical abnormalities may be transported to and adsorbed by apparently normal peripheral tissues. Since this phenomenon was first demonstrated in malignant disease, the term "biochemical metastasis" has been proposed¹ to denote this transportation and induction of abnormal immunochemical specificities in apparently normal organs. The latest confirmation is by Dmochowski² of the State Hygienic Institute, Warsaw, who has studied the implanted tissue specificities in cases of chronic tuberculosis. The Polish immunochemist injected rabbits with aqueous, alcoholic and ether extracts of bovine caseous material and thus produced an antibovine serum. This antiserum gave strong precipitin and complement deviation reactions with extracts from both human and bovine tuberculous material but no reaction with similar extracts from normal human tissues. It was apparently "caseation specific." Twelve tuberculous, three chronic suppurative and fifteen nontuberculous, nonsuppurating cadavers were studied by means of this antiserum. Dmochowski found that both the tuberculous tissues and chronic suppurative tissues reacted strongly to the "caseation specific" antibody. Caseation specific reactions were also given by extracts from the apparently normal liver, kidney, spleen and heart muscle of the same cadavers. With few exceptions the nontuber-

1. Hirsfeld, L.; Halber, W., and Laskowski, J.: *Ztschr. f. Immunitätsforsch.* 64: 61 (Nos. 1 and 2) 1929.
2. Dmochowski, L.: *Ztschr. f. Immunitätsforsch.* 90: 363 (May) 1937.

culous, nonsuppurative cadavers were entirely negative in his control tests. Dmochowski interprets these results as evidence of a wide distribution of degeneration products from caseous and suppuration foci, and the deposit of these degeneration specificities in apparently normal tissues and organs. Other interpretations are, of course, possible.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Society News.—Dr. Henry W. F. Woltman, Rochester, Minn., will discuss "Postoperative Neuritis" before the San Diego Academy of Medicine June 21.—At a meeting of the San Diego County Medical Society May 24 Dr. Robert W. Lamson, Los Angeles, spoke on "Twentieth Century Auto-Intoxication."—Dr. George D. Huff addressed the San Diego County Obstetrical and Gynecological Society May 25 on "Utero-Salpingoscopy."—Dr. Edwin W. Schultz, Stanford University, addressed the Hollywood Academy of Medicine April 21 on "Property and Nature of Viruses."

Promotions in University Faculty.—The University of California Medical School, San Francisco, announces the following promotions on the faculty, among others:

Dr. Robert S. Stone, to professor of roentgenology.
Dr. John B. de M. Saunders, to professor of anatomy.
Frank W. Allen, Ph.D., to assistant professor of biochemistry.
Dr. Raymond J. Reitzel, to associate clinical professor of medicine.
Dr. John J. Sampson, to associate clinical professor of medicine.
Dr. Stacy R. Mettler, to associate professor of medicine.
Dr. John B. Lagen, to assistant professor of medicine and pharmacology.
Dr. Paul A. Gliche, to assistant professor of psychiatry.
Dr. Laurence Taussig, to associate clinical professor of dermatology.
Dr. Montague S. Woolf, to associate clinical professor of surgery.
Dr. H. Brodie Stephens, to assistant clinical professor of surgery.
Dr. George C. Hensel, to assistant clinical professor of orthopedic surgery.
Dr. Robert C. Martin, to associate clinical professor of otorhinolaryngology.
Dr. Lewis F. Morrison, to associate clinical professor of otolaryngology.

CONNECTICUT

Society News.—Dr. Charles H. Goodrich, Brooklyn, discussed "Public Health and Preventive Medicine in Private Practice" before the Hartford County Medical Association at its recent annual meeting, and Dr. Maurice T. Root, West Hartford, as retiring president spoke on "An Everyday Approach to Some Pressing Medical Problems."

Maternal and Infant Mortality.—The infant mortality rate in Connecticut in 1937 was 40.5 per thousand births as compared with 42.3 in 1936. The total number of deaths was 908. According to the Connecticut *Health Bulletin*, this is a reduction of about 70 per cent since 1901, when the rate was 138 per thousand births. The maternal mortality rate in 1937 was 2.9, a decrease over the rate for 1936 when it was 4.7.

Changes in Health Officers.—The following have been appointed health officers of the places indicated:

Dr. George S. Lambert, Killingly.
Dr. Arthur D. Marsh, Scotland.
Dr. Joseph L. Roy, Thompson.
Dr. Francis Brewer, Brookfield.
Dr. Wilfred J. T. Robinson, East Windsor.
Dr. John H. McLaughlin, Voluntown.
Dr. William L. Higgins, Andover.

FLORIDA

Personal.—Dr. Alvin L. Stebbins, Punta Gorda, has been appointed health officer of Escambia County, succeeding Dr. William H. Pickett, Pensacola, resigned. Dr. Stebbins has recently been health officer of Franklin, Gulf, Liberty and Calhoun counties.—Dr. Haynsworth D. Clark, Fort Pierce, was named president-elect of the Florida Railway Surgeons Association at its annual meeting in Miami and was reelected secretary-treasurer.

Society News.—The Dade County Medical Society was addressed recently by Drs. Warren W. Quillian, Coral Gables, on pediatrics and Herman Boughton, Miami Beach, pneu-

monia.—At a meeting of the Duval County Medical Society in Jacksonville April 5 a symposium on deficiency diseases was presented by Drs. William W. Kirk, Ernest B. Milam and Ferdinand Richards, all of Jacksonville.—The Pinellas County Medical Society was addressed in St. Petersburg April 15 by members of the Hillsborough County Medical Society; the speakers, all of Tampa, were Drs. Henry Mason Smith on "Pituitary Tumor"; Robert G. Nelson, "A Plea for Obstetrics as a Specialty" and James T. Cowart, "Practical Pediatrics."

GEORGIA

Hardman Cup Honor to Dr. Sydenstricker.—The name of Dr. Virgil P. W. Sydenstricker, professor of medicine, University of Georgia School of Medicine, Augusta, will be inscribed on the L. G. Hardman Loving Cup, it was announced at the annual meeting of the Medical Association of Georgia. This honor is awarded annually to the physician considered to have rendered the most distinguished medical service during the previous year. The cup was given to the state medical association by the late Governor Hardman, who was a member of the association for more than fifty years, graduating from the University of Georgia Medical Department in 1876 and Bellevue Hospital Medical College in 1877.

ILLINOIS

Society News.—Dr. George W. Hall, Chicago, addressed the Peoria City Medical Society in Peoria April 19 on "The Relationship Between the Physical and Psychic Disturbances of the Patient." Dr. Harry E. Mock, Chicago, addressed the society April 5 on "Management of Craniocerebral Injuries." Dr. Willis S. Lemon, Rochester, Minn., discussed "The Development and Metamorphosis of the Primary Tubercle" before a recent meeting.—Dr. Quitman U. Newell, St. Louis, discussed "Prolapsus Uteri" before the Adams County Medical Society in Quincy May 9.

Chicago

Capps Prize Awarded.—Dr. Ronald R. Greene has received the Joseph A. Capps Prize of \$500 for 1937 for his work on "Experimental Production of Intersexuality in the Female Rat." Founded by the late Dr. Edwin R. LeCount, the award is made annually by the Institute of Medicine of Chicago for the most meritorious investigation in medicine by a graduate of a recognized medical school in Chicago within two years after the completion of an internship or of one year in laboratory work. Dr. Greene graduated at Northwestern University Medical School, Chicago, in 1935.

Patients with Purpura Haemorrhagica and Polycythemia.—Members of the department of medicine of the University of Illinois College of Medicine are interested in studying patients with purpura haemorrhagica and polycythemia. Physicians are asked to communicate with Dr. Major H. Worthington, superintendent of Research and Educational Hospital, 1819 W. Polk Street, for additional information concerning the free hospitalization of these patients. Case histories of the patients should be sent to the hospital. The service is available only to residents of Illinois.

INDIANA

University News.—The Indiana University School of Medicine, Indianapolis, will receive a bequest of \$5,000 under the will of the late Dr. J. P. Heath, Fishers, newspapers reported recently. Dr. Heath also bequeathed his medical library to the school.

Hospital News.—The new \$250,000 ward building at the Logansport State Hospital was dedicated May 12; it will provide accommodations for 219 mental patients.—The new wing of the Witham Memorial Hospital, Lebanon, was dedicated May 12; 45 per cent of the approximate \$100,000 cost of the unit was paid by the federal government and the balance by Boone County; the hospital now has a capacity of sixty beds.

District Meetings.—A symposium on gallbladder diseases was presented before the Eighth District Medical Society in Muncie May 10 by Drs. Clarence F. G. Brown and John L. Lindquist, Chicago, and Byrl R. Kirklin, Rochester, Minn. Dr. Frank H. Lahey, Boston, was the speaker at the banquet.—Dr. Rettig A. Griswold, Louisville, Ky., addressed the Fifth District Medical Society in Terre Haute May 6 on "Surgical Procedures in Office Practice." This meeting was a joint dinner session with the Vigo County Medical Society, the Terre Haute Academy of Medicine and the Aesculapian Society of the Wabash Valley.—At a meeting of the Sixth District Medical Society in Richmond May 5 the speakers were Drs.

Gerald W. Gustafson, Indianapolis, on "Normal Delivery and Breech Presentation"; Lyman T. Meiks, Indianapolis, "Care of the Newborn and Premature Infant," and Henry Close Hesselstine, Chicago, "Treatment of Hemorrhage of Late Pregnancy."

IOWA

Public Health Meeting.—The twelfth annual meeting of the Iowa Public Health Association was held at the Hotel Fort Des Moines May 10 under the presidency of Dr. William Woodburn, Boone. Out of state speakers included Drs. Allan J. McLaughlin, Ann Arbor, Mich., on "Local Health Organization in Relation to Public Health" and Florian E. Schmidt, Chicago, "Management of the Pneumonias." Dr. Walter L. Biering, Des Moines, state health commissioner, spoke on "Marshaling Health Forces Against Pneumonia."

Twin Lakes District Meeting.—The dry diagnostic clinic and fifteenth annual assembly of the Twin Lakes District Medical Society will be held at Rockwell City High School, Rockwell City, June 23. The speakers on the program will include Drs. Charles T. Obermann, Cherokee, "The Problem Drinker," and James F. Kelly, Omaha, "Some Recent Advances in Radiation Therapy"; others will include Drs. George B. Eusterman, Rochester, Minn.; Rollin Russell Best and William R. Hamsa, Omaha; James H. Bloomfield, Chicago, and Orval R. Withers, Kansas City. The clinics will cover practical surgery, office management of some surgical conditions of the extremities, gynecology, clinical allergy and gastrointestinal malignant conditions. There will also be an after-dinner symposium on medical economics.

Society News.—Dr. Clarence E. Broderick, Cherokee, addressed the Cherokee County Medical Society April 11 on "Interstitial Keratitis of the Cornea."—At a meeting of the Crawford County Medical Society in Denison April 12, the speakers were Drs. Robert D. Schrock, Omaha, on "Fractures of the Lower Third of the Forearm and Wrist" and James W. Graham, Sioux City, "Fractures About the Elbow."—Dr. Goronwy O. Broun, St. Louis, discussed "The Problem of Arteriosclerosis" before the Scott County Medical Society in Davenport April 5.—At a meeting of the Tama County Medical Society in Dysart April 21 Dr. Milo G. Meyer, Marshalltown, spoke on psychoneurosis.—The Four County Medical Society (Allamakee, Clayton, Fayette and Winnebago) was addressed at Postville April 5 by Drs. Arthur B. Hunt and John M. Waugh, both of Rochester, Minn., on sterility and surgery of the female pelvis, respectively.

KANSAS

Medical Books in High School Library.—Fifty-two books on medical and public health were recently placed in the Hoisington High School by the Barton County Medical Society. The books were selected by a committee of the society in cooperation with a local library committee and the cost was defrayed by a bequest in the will of a local citizen. The books were selected from a list prepared by the Kansas Women's Auxiliary.

MAINE

Personal.—Dr. Oscar R. Emerson, Newport, has been appointed a member of the state board of registration of medicine succeeding Dr. Franklin A. Ferguson, Portland, resigned. Dr. Ferguson was also chairman of the board, and a successor will be elected at a meeting in July.

Anniversary of Memorial Library.—The Frederic Henry Gerrish Memorial Library observed its first anniversary with a special ceremony May 26 at the Central Maine General Hospital, Lewiston. The program included clinics, ward walks and a round table discussion by Dr. Reginald Fitz, Wade professor of medicine, Boston University School of Medicine. At the banquet in the evening, Dr. Ralph W. Wakefield, Bar Harbor, president, Maine Medical Association, spoke and Dr. Fitz discussed "The Case of the Forsaken Pamphlet."

Society News.—The Cumberland County Medical Society was addressed April 22 by Dr. Henry R. Viets, Boston, on "Acute Lymphocytic Meningitis and Other Virus Diseases of the Nervous System."—Dr. Samuel H. Proger, Boston, addressed the Kennebec County Medical Association in Gardiner April 21 on "The Heart After Forty." Dr. Ralph W. Wakefield, Bar Harbor, also spoke.—Dr. Arthur W. Allen, Boston, discussed "Peptic Ulcer" before the Penobscot County Medical Association in Bangor April 18.—Dr. Harold E. Pressey, Bangor, discussed "Some Physiotherapy Methods in Modern Medicine" before the Waldo County Medical Society May 26.

MICHIGAN

Graduate Course in Obstetrics.—The federal maternal welfare committee, through the state department of health and the department of graduate medicine, University of Michigan, Ann Arbor, is sponsoring a graduate course in obstetrics at the University Hospital. Two practicing physicians have been appointed for intervals of two weeks during which time they live in Maternity Hospital. The following were appointed by the directors of the Michigan Maternal Welfare Committee: April 18-30, Drs. Clark G. Porter, Traverse City, and Fred E. Murphy, Cedar; May 2-14, Drs. Wesley H. Mast, Petoskey, and Gilbert B. Saltonstall, Charlevoix; May 16-28, Drs. Clarence G. Clippert, Grayling, and Benton A. Holm, Cadillac; May 30-June 11, Drs. Michael R. Murphy, Cadillac, and Raphael W. Albi, Lake City; June 13-25, Drs. Hugh F. Mulenmeister, Bear Lake, and Ernest C. Hansen, Manistee.

Personal.—Dr. Anthony J. J. Rourke, New York, has been appointed assistant director of University Hospital, Ann Arbor, succeeding Mr. George P. Bugbee, who resigned to become superintendent of the Cleveland City Hospital. Dr. Rourke graduated at the University of Michigan Medical School.—Dr. Milton Shaw, Lansing, immediate past president of the Ingham County Medical Society, was recently presented with a silver tray on which was engraved the signature of every member of the society in appreciation of his services.—Life membership in the Bay County Medical Society was conferred on Dr. Charles H. Baker, Bay City, at its meeting May 25. Dr. Baker was president of the Michigan State Medical Society in 1919.—Dr. George C. Stucky, for thirteen years superintendent of the Ingham County Tuberculosis Sanatorium, Lansing, has resigned to work on a rural health project being conducted in seven counties by the W. K. Kellogg Foundation, Battle Creek.—Dr. Wayne S. Ramsey, Harrisburg, Pa., president of the Washtenaw County Medical Society in 1934, is the new secretary of the Michigan Crippled Children Commission.—Dr. Richard M. Johnson, assistant professor of medicine, Wayne University College of Medicine, Detroit, has been appointed medical director of Eloise Hospital, Eloise.

MINNESOTA

Society News.—At a meeting of the Washington County Medical Society, April 12, Dr. Carl L. Larsen, St. Paul, discussed sinus disease.—At a meeting of the Minnesota Academy of Medicine in St. Paul May 11, the thesis of Dr. Emmett V. Kenefick was entitled "Nontuberculous Spontaneous Pneumothorax."

Personal.—Dr. Carl C. Chatterton during April was awarded the International Distinguished Service Medal for 1937 by the Cosmopolitan Club of St. Paul for his work with crippled children at the Gillette State Hospital. The medal is given each year to a resident of the city who during the past twelve months has rendered noteworthy and unselfish civic service without remuneration.

University News.—The board of regents of the University of Minnesota announces a gift of \$10,000 from Mrs. John Dwan, the mother of Dr. Paul F. Dwan of the department of pediatrics, for the inauguration of a serum center at the university. A gift of \$7,300 was also announced from the Citizens Aid Society, Minneapolis, for the purchase of an additional roentgen therapy machine for the Cancer Institute.

NEW HAMPSHIRE

Personal.—At a meeting of the Strafford County Medical Society in Rochester, April 27, the following were made honorary members: Drs. Roscoe G. Blanchard, Dover, Louis W. Flanders, Dover, John H. Bates, East Rochester, and Forrest L. Keay, Rochester. Dr. Samuel F. Marshall, Boston, discussed acute conditions of the abdomen.

Society News.—Dr. Dwight O'Hara, Boston, addressed the Dover Medical Society May 5 on "Scarlet Fever and Streptococci."—At a meeting of the Rockingham County Medical Society at Portsmouth recently Dr. James Sanders, among others, spoke on "Traumatic Injuries of the Extremities."—Dr. Halsey B. Loder, Boston, discussed "Emergency Treatment of Conditions That Arise in General Practice" before the Belknap County Medical Society in New Hampton April 5.

NEW JERSEY

Adler Prize Awarded to Dr. Stanley.—Harvard University, Cambridge, has awarded the Isaac Adler Prize of \$2,000 to Wendell M. Stanley, Ph.D., Rockefeller Institute for Medical Research, Princeton, for his work on the isolation of a

crystallizable factor which has developed a new approach in the study of viruses and stimulated a widespread interest among workers in this field, according to the *New York Times*. The Adler Prize was founded in 1934 by a bequest of \$20,000 made by Mrs. Frida Adler, New York, in memory of her husband. Dr. Stanley was recently awarded the Rosenberger Medal of the University of Chicago for his work on viruses.

Vineland School Fifty Years Old.—The Training School at Vineland, an institution for mentally deficient children, recently celebrated the fiftieth anniversary of its founding. Mr. Edward R. Johnstone has been director since 1900. In 1906 the research laboratory was established with Henry H. Goddard, Ph.D., now of Ohio State University, as the director. Under his direction the Binet intelligence test was first used in the United States, it is said, and it was at Vineland that he produced his book "The Kallikak Family." Edgar A. Doll, Ph.D., is now director of the laboratory. A special study of birth injuries has been made in the past five years with the cooperation of the New Jersey Crippled Children's Commission and the federal Children's Bureau.

NEW YORK

Compulsory Examination for License to Marry.—A law has been enacted requiring a physician's examination and serologic test of each applicant for a marriage license in New York. The law went into effect immediately but is not applicable to marriage licenses issued before July 1.

Society News.—Dr. Charles H. Goodrich, Brooklyn, president of the Medical Society of the State of New York, addressed the Medical Society of the County of Albany April 27 on "Our Position, Our Responsibilities and the Outlook."—Dr. Wilson G. Smilie, New York, addressed the Medical Society of the County of Nassau, Mincola, April 26, on "The Present Day Concept of Public Health."

Outbreaks of Gastroenteritis.—Ninety-four persons were affected in an outbreak of gastroenteritis in East Pembroke, Genesee County, between February 23 and March 7. The illness was traced to a well which supplied water for a school in which most of the cases occurred. The remaining cases were in households near the school which also used the water. Bacteriologic examination showed *B. coli*.—Forty-three out of forty-five persons who attended a church supper in the town of Brasher, St. Lawrence County, March 24, became ill of gastroenteritis.

Conference of Health Officers and Public Health Nurses.—The annual conference of health officers and public health nurses will be held at Saratoga Springs, June 28-30. According to the preliminary announcement, the speakers will include Gov. Herbert H. Lehman, Drs. Edward S. Godfrey Jr., Albany, state commissioner of health; William A. Groat, Syracuse, president of the Medical Society of the State of New York; Ludvig Hektoen, executive director, National Advisory Cancer Council, Washington, D. C.; Paluel J. Flagg, New York, chairman of the committee on asphyxia of the American Medical Association, and Louise Pearce, Princeton, N. J., of the Rockefeller Institute for Medical Research.

New York City

The Graduate Fortnight.—The eleventh annual Graduate Fortnight of the New York Academy of Medicine will be held October 24 to November 4, it is announced. This year's subject will be "Diseases of the Blood and Blood-Forming Organs." All members of the medical profession are invited to attend. Information may be obtained from Dr. Mahlon Ashford, New York Academy of Medicine, 2 East One Hundred and Third Street, New York.

Society News.—At a meeting of the Association for the Advancement of Industrial Medicine and Surgery, Inc., May 18, the speakers were Drs. Arthur M. Master on "Precipitating Factors in Coronary Artery Thrombosis"; Louis Faugeres Bishop Jr., "Cardiovascular Syphilis in Industry," and Abram Wilbur Duryee, "The Peripheral Vascular System."—A symposium on the endocrine glands was presented at a meeting of the International Spanish Speaking Association of Physicians, Dentists and Pharmacists recently by Drs. Frank H. Lahey, Boston; Michael G. Wohl, Philadelphia; Andre Crotti, Columbus, Ohio, and William Seaman Bainbridge.

Dr. Tillett Made Professor of Medicine.—Dr. William Smith Tillett, professor of bacteriology and director of the bacteriologic laboratories, New York University College of Medicine, has been appointed professor of medicine to fill the vacancy created last year by the death of Dr. John Wyckoff. The appointment is effective in the fall. A native of Charlotte,

N. C., Dr. Tillett graduated at Johns Hopkins University School of Medicine, Baltimore; he served overseas during the World War and then joined the staff of the Rockefeller Institute for Medical Research. Prior to his appointment at New York University, Dr. Tillett served as associate professor of medicine and director of the biologic division of the department of medicine at Johns Hopkins.

Library Report.—The annual report of the library of the Medical Society of the County of Kings and the Brooklyn Academy of Medicine shows that 16,570 readers used the library during 1937. The number of books consulted in the library was 64,511 and the number taken home was 12,702. All these figures were increases over the previous year. This library receives support from numerous special societies, some of which use the society's building for their meeting. A number of organizations and individuals present subscriptions to periodicals to the library. The report points to a serious need for expansion of space to accommodate its growing collections. The library purchased 951 volumes, received for review 452 and received as gifts 168. The number of current serial publications received was 1,562.

New York Hospital and Cornell Seek Endowment.—The New York Hospital and Cornell University Medical College began a campaign March 31 for an endowment of \$17,000,000 to enable the institution to use its facilities and enlarge its program of research. It is said that the annual deficit has been reduced by two thirds through careful management, but that further curtailment would impair the service to patients and the facilities for research and education. The present annual operating loss of nearly a million dollars is caused by the free and partly free care of patients, it was said. Urgent requirements of the hospital are additional beds in the department of medicine, initial development of surgical specialties, opening of unused floors and an endowment for the school of nursing. In the college the departments are existing at the lowest level consistent with first class teaching, an announcement said. Last year the hospital cared for 20,000 bed patients and 46,000 in the outpatient department. The total operating expenses for the year were \$3,879,674.86.

NORTH CAROLINA

Health Officer Honored.—Dr. George M. Cooper, assistant state health officer since 1923 and director of the division of preventive medicine and health education, state department of health, Raleigh, was recently presented with a silver letter opener bearing his initials and the dates 1915-1938 by his associates in the division. The gift was in recognition of his service with the state board for twenty-three years.

District Meetings.—The Eighth District Medical Society was addressed in Greensboro April 26, among others, by Drs. Fred M. Patterson, Greensboro, on "Surgery of the Prostate, Preoperative Studies and Preparation"; Robert W. Mathews, Greensboro, "Classification and Mechanism of the Anemias," and Charles L. Haywood Jr., Elkin, "The Erythrocyte Sedimentation Rate in the Acute Abdominal Conditions."—At a meeting of the Fifth District Medical Society in Sanford April 26, the speakers included Drs. Maurice Barnes Woodhall, Durham, on "Diagnosis and Treatment of Acute Head Injuries," and Asa M. Lehman, Fort Bragg, lieutenant colonel, U. S. Army, "Intestinal Obstruction."

NORTH DAKOTA

Personal.—Dr. Clyde E. Stackhouse, Bismarck, has been appointed medical referee of the North Dakota State Board of Public Welfare, succeeding Dr. William H. Bodenstab, Bismarck.—Dr. Oliver S. Craise, Towner, has been appointed superintendent of the McHenry County Board of Health.—Dr. Robert Gillam White, formerly of Ann Arbor, Mich., has been appointed in charge of a new district branch of the North Dakota State Department of Health with headquarters at Valley City.—Dr. Francis Weldon Ford, Minnewaukan, has been appointed health officer of Devils Lake.

PENNSYLVANIA

Personal.—Dr. Edwin A. Nicodemus, who recently retired as chief of the surgical staff of the Harrisburg Polyclinic Hospital, was recently honored with a testimonial dinner at the Hotel Harrisburger by members of the staff.

Society News.—At a meeting of the Lycoming County Medical Society in Williamsport June 10 Dr. Samuel O. Pruitt, Philadelphia, spoke on "Prognosis and Management of the Average Case of Tuberculosis."—At a meeting of the Fayette

County Medical Society in Uniontown June 2, Drs. Harold L. Mitchell, Pittsburgh, discussed mental health problems and Charles H. Henninger, Pittsburgh, mental hygiene activities in Pennsylvania. —The Dauphin County Medical Society, Harrisburg, was addressed June 7 by Dr. John C. Hirst, Philadelphia, on "Maternal and Fetal Complications of Multiple Pregnancies."

TEXAS

State Medical Election.—Dr. Leopold H. Reeves, Fort Worth, was chosen president-elect of the Texas State Medical Association and Dr. Ernst W. Bertner, Houston, was inducted into the presidency. Vice presidents are Drs. Lewis B. Holland, Wichita Falls; James W. Ward, Greenville, and Frederick B. Shields, Victoria. Drs. Holman Taylor and Khleber H. Beall, both of Fort Worth, were reelected secretary and treasurer respectively. The 1939 session will be in San Antonio.

Society News.—Drs. Robert M. Purdie and John R. Phillips, Houston, addressed the Austin County Medical Society, Sealy, recently, on "Indigestion as a Symptom" and "Ulcer and Carcinoma of the Stomach and Duodenum" respectively. —Drs. Charles W. Stevenson and Julius A. Heyman, Wichita Falls, addressed the Childress-Collingsworth-Hall Counties Medical Society, Memphis, recently, on "Gastrointestinal Diagnosis" and "Peritonitis and Its Treatment" respectively. —Speakers at a meeting of the Falls County Medical Society recently were the following from San Antonio: Dr. Lewis M. Helfer, on "Diagnosis of Brain Tumors"; William E. Durbeck, D.D.S., "Fractures of the Jaws" and Dr. John D. Gleckler, "Tic Douloureux." —Drs. Richard B. DeLee, Shreveport, La., and Walter Grady Reddick, Dallas, addressed the Gregg County Medical Society, Longview, March 10, on "Treatment of Hay Fever" and "Use of Sulfanilamide in Internal Medicine" respectively. —A symposium on diseases of the liver was presented before the Tarrant County Medical Society, Fort Worth, March 1, by Drs. Hiram C. Thomas, Clarence C. Garrett, Frank W. Halpin and Charles H. McCollum Jr.

WEST VIRGINIA

Annual Symposium.—The fourth annual symposium, presented by the Golden Clinic, Davis Memorial Hospital, Elkins, will be held June 25. The speakers will include:

- Dr. Harry E. Mock, Chicago, Skull Fracture.
- Dr. George K. Fenn, Chicago, Peripheral Circulatory Failure versus Myocardial Failure.
- Dr. Fred H. Albee, New York, Massive Resection of Bone Sarcoma with Immediate Bone Graft Replacement.
- Dr. Lester Hollander, Pittsburgh, Dermatologic Problems of the General Practitioner.

The West Virginia Heart Association will hold a round table luncheon. Dr. John E. Cannaday, Charleston, will be the toastmaster at the banquet in the evening; the speakers will be Drs. Mock and Albee on "Conservative Treatment of Gallbladder Disease" and "Joint Reconstruction" respectively.

WISCONSIN

Society News.—Dr. Hans Adolph Krebs of the department of pharmacology, University of Sheffield, England, lectured before the University of Wisconsin Medical Society April 25 on "Recent Advances in Intermediary Carbohydrate Metabolism." —The Medical Society of Milwaukee County was addressed May 13 by Drs. Dexter H. Witte on "What Is Socialized Medicine?" and Newell C. Gilbert, Chicago, "Role of the Coronary Circulation in Cardiac Insufficiency." A school of first aid and health was conducted during May by the local chapter of the American Red Cross in conjunction with the first aid committee of the society.

PHILIPPINE ISLANDS

New Officers of Philippine Medical Association.—Dr. Jose C. Locsin, Silay, Occidental Negros, was elected president of the Philippine Islands Medical Association at its thirty-fifth annual meeting in Zamboanga, April 27-29. Vice presidents are Drs. Pedro A. Rodriguez, Zamboanga, and Alberto Tupas, Manila, and Dr. Antonio S. Fernando, Manila, is secretary. The program included the following speakers:

- Dr. Tupas, The Care of the Premature Infant in the Tropics.
- Drs. Mariano C. Icasiano and Florencio Z. Cruz, Manila, The Normal Growth of Filipino School Children.
- Dr. Teofilo S. Morales, Baguio, Artificial Pneumothorax in the Treatment of Lobar Pneumonia.
- Drs. Lucio D. Abad and Manuel C. Maghoo, Manila, Foreign Body in the Frontal Sinus (Spark-Plug of an Automobile) of Fifteen Years' Duration.
- Dr. Antonio Ejercito, Manila, Biological Control of Anopheles.

GENERAL

Campaign Against Fourth of July Accidents.—How to make the Fourth of July safe and sane is the theme of literature now being distributed by the National Society for the Prevention of Blindness in its current campaign to reduce Fourth of July accidents. The material contains suggestions for editorial writers and mothers and includes a reprint of the first annual summary of Fourth of July accidents, published in *THE JOURNAL*, Nov. 27, 1937, page 1806.

Changes in Status of Licensure.—The State Medical Board of Ohio reports the following actions:

- Dr. Phares P. Mauk, Portland, Ore., license revoked recently for violation of the Harrison Narcotic Act.
- Dr. Robert I. McPhail, formerly of Arcadia, license restored January 3; it was suspended in January 1937.

The Texas State Board of Medical Examiners reported the following:

- Dr. Richard Hubbard Lindley, San Angelo, license suspended for two years by order of the district court January 5.

The department of licenses of the state of Washington recently reported the following:

- Dr. Robert William Rose, Davenport, license revoked Dec. 17, 1937, for unprofessional conduct.

Special Society Elections.—At the semicentennial meeting of the American Pediatric Society in Great Barrington, Mass., May 7, Dr. Clifford G. Grulec, Evanston, Ill., was elected president; Dr. DeWitt H. Sherman, Buffalo, vice president, and Dr. Hugh McCulloch, St. Louis, reelected secretary. —Dr. Ernest H. Gaither, Baltimore, was elected president of the American Gastro-Enterological Association at its recent annual meeting and Drs. Irvin Abell, Louisville, Ky., and Andrew C. Ivy, Chicago, vice presidents. Dr. Russell S. Boles, Philadelphia, is secretary. The 1939 session will be held at the Hotel Claridge, Atlantic City, May 1-2. —Newly elected officers of the American Otological Society include Drs. Isidore Friesner, New York, president, and Horace Newhart, Minneapolis, vice president. Dr. Thomas J. Harris, New York, is secretary.

Restrictions Removed from Rockefeller Gifts.—Trustees of the Rockefeller Foundation and the General Education Board, also financed by Rockefeller funds, recently announced that gifts distributed by them are now free from restrictions as to their use for specific purposes. It was pointed out that the new purposes should be as reasonably related to the original purpose as may be found practicable, having regard to intervening changing conditions. The following conditions, however, were made for the change: Ten years after the date of a gift the income may be used for some purpose other than the original one; five years after the date of the gift 5 per cent of the principal may be used each year for any purpose for which the income may then be used; after twenty-five years any part or the whole of the principal may be used for some other purpose. This action was taken in view of the impending liquidation of the General Education Board, it was announced, and uncertainty as to further opportunities for expenditure by the Rockefeller Foundation. The Laura Spelman Rockefeller Memorial and International Education Board have already been merged or liquidated.

Reports of Swindlers.—A man has recently been using the name of Dr. Malcolm T. MacEachern, associate director of the American College of Surgeons, Chicago, to swindle physicians and hospitals, it is reported. This man tells a story of having lost his wallet or having his car broken down and wants to borrow money to get him out of his difficulties. He speaks familiarly of physicians and appears to be well versed in matters pertaining to medicine. He is between 40 and 50 years old, about 5 feet 8 inches tall and weighs about 165 pounds; has a fair complexion, sandy hair; is well groomed and talks rapidly and suavely. It is also reported that persons are visiting hospitals posing as representatives of the American College of Surgeons. One such reported from Waynesburg, Va., gave the name Robert T. Clayton. He also claimed a connection with the American Medical Association. Accredited representatives of these organizations carry identification which they will produce on request. —A Kentucky physician has reported the activities of a man using the name Walter S. Cole, who claims to be an advertising agent. His plan was to solicit physicians to have their names on key tags or cards for hotel rooms as "house physician." This practice is customary in that section, it was said. Mr. "Cole" gave a receipt for payment for handling this service, but when a letter was sent to the address he gave, 1472 Broadway, New York, the letter was returned marked "Fictitious." —A trail of bad checks was recently left in Marseilles, Ill., by a man who

posed as a physician giving the name Dr. George E. Knight, Detroit. He rented an office, ordered an automobile and joined in social activities in the town. He asserted that he had opened an account in Grand Ridge, a neighboring town, but when various persons who had cashed his checks attempted to cash them in Grand Ridge it was found the man had no funds there. He was described as about 35 years old, 6 feet tall, blond and slightly bald. Files of the biographic department and the Bureau of Investigation of the American Medical Association do not show a physician of this name.

CANADA

Personal.—Dr. Brabazon J. Hallowes has been appointed health officer of Alexis Creek.—Dr. Donald H. Williams, Vancouver, has been appointed director of the division of venereal disease control of the department of health of British Columbia.

Banting Chairman of Research Committee.—The National Research Council of Canada has recently appointed a committee to study the organization of medical research in Canada, with Sir Frederick Banting, Toronto, as chairman. The immediate purposes of the committee were stated to be: to receive suggestions for requirements in respect of medical research and in matters related thereto; to consider by whom the investigations required can best be carried out and to make proposals accordingly; to correlate the information when secured and to make it available to those concerned, and to do such other things as the committee may deem advisable to promote research. One of the first steps will be to make a survey of the work in progress at various centers to determine how the activities of the various institutions concerned may be developed to the best possible advantage, according to *Science*. Appointment of the committee was recommended at a nationwide conference held recently in Ottawa and attended by representatives of all the medical schools, organizations and institutions concerned in medical research in the dominion.

FOREIGN

Health Survey in Belgium.—The Health Committee of the League of Nations at a meeting in February agreed to cooperate with the Belgian Ministry of Health in making a survey of health conditions of the population and of the equipment, organization, methods and efficiency of the health services of Belgium. The action was taken in answer to a request of the ministry of health, of which Dr. Rene Sand is secretary general. A committee was appointed to make the survey with Professor Parisot, Paris, as chairman, to make the study early in the summer.

Manson Medal to Sir Leonard Rogers.—The Royal Society of Tropical Medicine and Hygiene presented its Manson Medal to Major General Sir Leonard Rogers, retired, at its annual meeting June 16. The medal is awarded triennially "to the living author of such work in any branch of tropical medicine or tropical hygiene as the council may consider deserving of the honor." Sir Leonard formerly served as president of the society and as professor of pathology at the Medical College, Calcutta. He received the Moxon Gold Medal of the Royal College of Physicians of London and the Fothergillian Gold Medal of the Medical Society of London. He has been a frequent contributor to the literature on tropical medicine.

Government Services

Annual Report of Surgeon General of Navy

The Bureau of Medicine and Surgery of the U. S. Navy in its report for the calendar year 1936 listed 367 deaths from all causes, a rate of 2.95 per thousand. Motor vehicle accidents occupied first place as a cause of accidental death, as it did in 1930, 1931, 1934 and 1935. Previous to 1930, drowning was the leading cause of accidental death.

There were 55,614 admissions for all causes in the calendar year 1936, with a rate of 447.03 per thousand. Fifty-two of the fifty-six deaths and 712, or 88.3 per cent of the admission charged to motor vehicles, were the result of injuries received while the men were on leave or liberty. Of the 806 motor vehicle injuries, 620 were incurred in passenger-carrying automobiles, 112 in motorcycles, fifty-one in trucks and twenty-three in other motor vehicles. There were 1,876 admissions for accidental injuries and poisoning incurred while on leave

or liberty. When considered from the point of view of loss of life or serious injury to naval personnel it can be said that only one disaster occurred during the year 1936. A gun explosion occurred on the U. S. *Marblehead* July 28, injuring eleven enlisted men. Three deaths and three "invaliding from the naval service" resulted from this explosion. There were fifty-one instances of suicide and attempted suicide with twenty-nine deaths, a decrease of seven and seven respectively as compared with 1935. In 1936 there were 1,322 persons invalided from the service. Of the total 1,141,908 sick days for the navy in 1936, naval hospitals were charged with 841,295, or 73.7 per cent. This number of hospital sick days, incurred by 23,347 active duty patients, represents 1.85 per cent of all naval personnel as constantly under treatment in naval hospitals throughout the year. In addition there were 46,299 sick days for 2,154 patients on the hospital ship U. S. S. *Relief*; 3,905 sick days for twenty tuberculous patients at the naval unit, Fitzsimons General Hospital, U. S. Army, Denver, and 10,013 sick days for eighty-eight insane patients at the naval unit at St. Elizabeth's Hospital, Washington, D. C. A total of 23,347 persons in the navy, 5,195 Veterans' Administration patients and 7,690 supernumerary patients underwent treatment in naval hospitals, or a grand total of 36,232 persons treated in naval hospitals with 1,259,541 sick days. There were 187 original admissions for malaria and three cases of tularemia. The admission rate for communicable diseases transmissible by oral and nasal discharges was 142.47 per thousand for 1936.

Venereal diseases occupied second place among all causes of morbidity and contributed the largest number of sick days of any group. This group has maintained this position since 1925, except for the year 1930. The admission rate for 1936 was 65.49 per thousand, 12 per cent less than for 1935. There were 1,213 cases of chancroidal infections, 5,453 cases of gonococcal infections, 1,377 cases of syphilis, 102 cases of venereal lymphogranuloma and three cases of verruca acuminata (venereal), or a total of 8,148 cases admitted during the year. During the past twelve years infections acquired prior to enlistment have not been included in the admission rate. There were 158,920 sick days reported for these diseases. The noneffective ratio, or the daily average number of persons on the sick list, was 348.99 per hundred thousand, 5 per cent less than for 1935.

The admission rate for all forms of tuberculosis was 136 per hundred thousand as compared with 131 in 1935. In addition to 169 original admissions representing disease acquired in the naval service in 1936 there were seventy-five cases remaining from the previous year, five readmissions, nine in which the disease or condition was a complication or sequel of some other condition, and five cases in which the disability was reported as existing prior to enlistment. All forms of tuberculosis were responsible for 34,536 sick days, or a daily average of 76 per hundred thousand patients constantly on the sick list.

The medical corps numbered 781 medical officers at the end of the fiscal year, June 30, 1937, which number is short of the number required, the report said. Although appropriation was made for 1938 for 851 officers, that number is still too small. During the fiscal year 1937 twenty medical officers received graduate instruction at the Naval Medical School, Washington, D. C., at the Marine Barracks, Quantico, Va., and at the Edgewood Arsenal, Edgewood, Md. In addition forty officers, eight nurses and five enlisted men took graduate work at various universities.

There is a continued shortage of qualified flight surgeons. One officer received training during the fiscal year at the Army School of Aviation Medicine, Randolph Field, Texas; five had been assigned for the present year. One flight surgeon each year completes the basic flying course at the Naval Air Station, Pensacola, Fla.; there are now four so qualified. Sixteen flight surgeons had flight orders on duty with active flying units.

The Naval Dispensary, which renders professional service to officers and men and their families in the District of Columbia and vicinity, reported 42,687 office calls and 11,915 house calls, 37,972 prescriptions filled, 8,689 laboratory examinations and 7,784 physical therapy treatments.

CORRECTION

Renal Mobility.—In the paper on this subject by Hess in *THE JOURNAL* May 28, page 1819, first column, third line from the bottom of the page, the word "prone" should have been "supine."

May 21, 1938.

Shortage of Nurses; Proposals to Improve Their Conditions of Work

Nursing is an arduous profession, but attempts at improvement of the conditions have so far been on a limited scale. The result is that we are faced with a shortage of nurses and reform has become a burning question. The London County Council, which employs 7,000 nurses in its hospitals, has already reduced their working hours from sixty-six to fifty-four per week, and it is now proposed to reduce them to forty-eight. The government appointed a committee to investigate and report on nursing services, to which the British Medical Association has submitted important evidence. They stated that there is an insufficiency of candidates of any type for the nursing profession, and that the shortage will become greater in the near future on account of extension of hospital accommodation, increasing complexity of medical and surgical procedures, and reduction of nurses' hours of work. The shortage appears to be due to the long and arduous training and to the exacting character of the work, with which the salaries are not commensurate. The methods of training and the conditions of service impose many restrictions on the probationer and the qualified nurse. Finally, many more attractive occupations are open to young women. It is generally agreed that hospital training should not begin before the age of 18. This means for many girls a gap after leaving school and beginning to train, so that many girls suited for and attracted to nursing are absorbed into other occupations. The conditions of training are arduous. When the probationer enters the wards her education is generally subordinated to the work of the hospital. She often has to attend lectures at the end of a full day or night of duty and even sit for the final examination on the morning after a night on duty. The examination questions are often outside her province.

The British Medical Association made the following recommendations: 1. Preprofessional training courses should be organized for girls between the ages of 16 and 18. 2. The preliminary state examination should exclude the theory and practice of nursing and consist of questions on anatomy, physiology and hygiene, which it should be possible to study before beginning professional training. 3. It should be possible to establish a group hospital system of training in order to overcome the difficulties of recognizing smaller hospitals for training and to give a more varied type of instruction. 4. A substantial improvement in the conditions of living and pay should be created. 5. There should be recognized a second grade of nurse to act in an assistant capacity.

New Technic for Radium Treatment of Carcinoma of Vulva

At a meeting of the North of England Obstetric and Gynaecologic Society, Dr. F. Ellis, medical director of the Sheffield Radium Centre, reported cases of carcinoma of the vulva in which complete healing had been obtained without necrosis by the use of uniform irradiation. He said that radium treatment had been discredited in the past by the high incidence of radium necrosis and local recurrences. However, modifications of the technic which insured more uniform irradiation of the growth had so transformed the outlook that radium could now compete with surgical measures. The most important modification was nursing the patients in the same posture as was adopted for insertion of the radium. The radium needles then retained their position throughout the treatment, and "crowding" after return of the patient to bed was avoided. When the growth was at the anterior end of the vulva, the needles were inserted with the

patient supine; when the growth involved the posterior end, the left lateral position was adopted, the patient being nursed in the same position; when the entire vulva was involved, the needles were inserted and nursing was carried out with the patient in the lithotomy position. When needles had to be placed on the surface of the growth, rubber pads were used to protect adjacent cutaneous surfaces and to keep the needles at known distances from the growth. After insertion of the needles a perforated rubber dressing was placed over the vulva, and irrigation with eusol (lime, 25 Gm.; sublimed sulfur, 50 Gm.; distilled water, q. s. ad 1,000 cc.) was done twice daily; an indwelling catheter was necessary. The best results were obtained when all the needles were placed 1.5 cm. apart. The theoretically better distribution, with the peripheral needles only 1 cm. apart (in which the periphery of the growth received half as much radiation again as the center) had not given such good results. The total dose ranged between 4,500 and 7,000 roentgen units. When interstitial irradiation of the glands was necessary, two planes of radium, 2 cm. apart, had to be used if any of the glands had a diameter of more than 1 cm. Important in the after-treatment was avoidance of hot baths and ointments. For the desquamation stage gentian violet was the best application. Moist desquamation was treated with 0.5 per cent solution of silver nitrate. Necrosis and residual carcinomatous areas called for excision.

Dr. Ellis distinguished five stages in the cases treated: (1) operable primary growths; (2) operable primary growths with movable glands; (3) operable growths; (4) recurrence after treatment; (5) hopeless conditions. In 1935 nine patients were treated; the three patients in stage 1 were still alive and free from disease, and the remaining six died. In 1936 fourteen patients were treated; four were in stage 1 and were alive and free from disease, and two of four in stage 2, one in stage 3 and one in stage 4 were alive. Radium had the advantages over surgical intervention of absence of shock and operative mortality, minimum damage to the urethra and wider application in advanced stages. However, operation eliminated necrosis; there was possibly less subsequent discomfort; precancerous tissues were removed, and there was the possibility of removing affected iliac glands.

Influence of Flying on the Circulation

The physiology and clinical aspects of aviation are considered of great importance in Germany and they are in process of thorough investigation. A discussion of this theme, by Docent Dr. G. Schlomka of Bonn, recently appeared in *Medizinische Klinik*. Both the peripheral and the central circulation are greatly influenced by flying. The special demands made by flying are based on two factors, speed and altitude, which differ fundamentally in one respect: altitude influences the circulation directly through diminished oxygenation of the blood, whereas the effect of speed is vastly more indirect. The speed factor is based on centrifugal force, always present whenever the course of the aircraft is altered. The entire organism of the flier is exposed to the same centrifugal forces as the ship. The circulation, however, possesses a certain peculiarity with respect to these forces; the vascular walls, especially those of the veins and capillaries, are especially pliant. Consequently the peripheral blood stream yields to the increase in hydrostatic internal pressure induced by the centrifugal force; this increase takes the form of a transverse dilatation of those vessels which are distal to the point of rotation. Since the blood volume is diminished, however, this means that blood in more or less considerable quantities will be transported peripherad. Owing to the great capacity of the abdominal circulation and the centrifugal speed, which in flying usually exerts its influence distad, large quan-

titles of blood will descend into the lower half of the body, with more or less complete emptying of the vessels of the upper half. Some vasomotor collapse will occur. The observations of different investigators of this problem are at variance. Many authors say that aerial travel increases the blood pressure, while others have observed that pressure is lowered during flight. The experimental data on the effect of centrifugal force on animals cannot unreservedly be applied to human beings although in some respects the correspondence is complete. The burden placed on a flier's circulation by the influence of altitude is also obscure. It is generally assumed that the altitude influences the circulation indirectly through the lowering of the pressure of the oxygen in the atmosphere and by the inhibition of oxygenation in the pulmonary blood supply. It has not been satisfactorily explained whether the manifestation of "early collapse" is participated in more by the peripheral circulation or by the heart. The effects of the hypoxemia on a damaged heart muscle will be manifested much earlier than if the heart is healthy. The practitioner should in general consider flying contraindicated for patients with ailments suggestive of angina pectoris, or coronary sclerosis or myocarditis. A trip that would entail flying at an elevation above 1,500 or 2,000 meters is particularly to be interdicted.

Cellular Metabolism and Inflammation

The Berlin Society of Physiology recently discussed the problem of cellular metabolism and inflammation. Professor Lohmann, who represented physiologic chemistry, based his observations on experimental studies. Inflamed cells are damaged body cells and possess marked functions of respiration and of aerobic glycolysis. At the site of the inflammatory process, physicochemical changes occur which are conditioned by the concentrations of oxygen, carbonic acid, lactic acid, bicarbonate and hydrogen ions. Lohmann described the reactions of normal and abnormal metabolism to these altered chemical concentrations. Cellular respiration is independent of the diminution of the sugar and bicarbonate values, as well as of the decrease in the p_{H_2} , whereas the aerobic glycolysis is completely dependent on each of the three factors. Since normal body cells have only the function of respiration without aerobic glycolysis, they maintain their undamaged metabolism until the onset of anaerobiosis; damaged cells, on the contrary, and this includes the normal blood cells and therefore the leukocytes of exudates, exhibit, under conditions of inflammation, a reduction in the aerobic glycolysis that may progress to the point of complete disappearance. The respiration alone will then remain and the cells apparently regain a normal metabolism. Examination of isolated muscle shows that inflammation renders the tissue incapable of function. Inflammation is a defense reaction of the organism.

Dr. H. Druckrey, assistant at the Berlin Institute of Pharmacology, the second speaker, discussed the metabolism of damaged tissues from the pharmacologic standpoint. Pharmaceutical substances may exert an important effect on "damaged" tissue. If metabolic conditions occur which differ from those of "normal" tissue, one may expect quantitative and qualitative differences in pharmacologic effect. Since most drugs participate in the normal metabolism, some may become detoxicated and others may first become toxic through collaboration with the metabolic processes. One important fact elicited by previous investigators is that nonspecific lesions induce first of all an increased metabolic rate. Furthermore, one may ask whether this increased metabolic rate following injury may not be evaluated as a manifestation of an increased functional capability of the cells. To clarify this problem, damaged cells were submitted to a second injury. These cells, despite the increased metabolism, were observed to be far less resistant than normal cells, the respiration of which was considerably less. The second injury

was followed by an immediate fall in the metabolic curve. Accordingly, repetition of similar injury elicits under certain conditions an effect completely opposite to that elicited by the initial injury.

April 27, 1938.

National Health Insurance for New Zealand

The New Zealand government's proposals for the establishment of a free and universal health service, for the payment of national superannuation commencing at the age of 60 years and for granting increases in most classes of state pensions were outlined by the prime minister in a statement issued April 2. The new schemes are to be financed in part by an increase in the wages tax from 8 pence to 1 shilling in the pound, and what is now known as the unemployment tax will become the social security contribution. The money raised in this way will be subsidized on a pound for pound basis out of general government funds. The list of benefits may be summarized as follows: Institution of a free health service for all classes of the community; payment of superannuation at the rate of 30 shillings a week, with an income allowance of £1 a week from other sources; increase in invalidity pensions from £1 to 30/- a week; payment of sickness benefits at rates to be determined; increase in the children's allowance to recipients of sustenance; increased widows' pensions on a wider classification; institution of orphans' pensions at 15/- a week; increase in family allowances from 2/- to 4/- per child; increase in miners' pensions and war veterans' allowances. The proposals outlined by the prime minister will be placed in detail before the special parliamentary committee which has been set up to advise the government. The prime minister has expressed the opinion that the proposed benefits will provide a condition of security unsurpassed anywhere in the world. The government's intention is to make the scheme operative from April next year.

A COMPREHENSIVE HEALTH SCHEME

The government proposes a "universal practitioner service free to all members of the community who need medical attention." The scheme embraces free hospital and sanatorium treatment, mental hospital care and treatment for the mentally afflicted, medicines and maternity benefits in cash payments including the cost of maintenance in a maternity home. It is proposed to introduce as well the following services when practicable: anesthetic, laboratory and radiology, specialist and consultant, massage and physical therapy, transport to and from hospitals and dental and optical benefits. It is also proposed to provide home nursing and domestic help when the necessary staff has been trained to make such a scheme practicable. The government will provide for extended health education as a continuation of measures to educate the public in the promotion of health and the prevention of disease. Regarding the operation of the system, lists would be issued of the doctors who chose to join the scheme, and people would be able to select the one they preferred, up to a certain limit. The practitioner's panel would, however, be restricted to a specific number, and to some extent he would also be able to choose his patients. The freedom of choice on the patient's part would be restricted only by his nearness to the doctor.

PAYMENTS DURING SICKNESS

The institution of the invalidity pension revealed the fact that there are people who cannot qualify as permanent invalids but for whom some security should be provided. The government's proposal is to establish a sickness benefit, but the rates and conditions will be determined after the parliamentary committee has heard the evidence. It is proposed to cooperate with the friendly societies and to utilize their services for paying this amount to their members. In addition to sickness benefits,

provision has been made for those who were not sick and not invalids but whom illness or injury has rendered incapable of earning a complete livelihood. The government will determine the rates in individual cases according to particular circumstances.

MEDICAL CRITICISM

These proposals of the national health insurance scheme are remarkably at variance with the suggestions offered at the request of the government by the New Zealand branch of the British Medical Association. The profession has consistently advocated that whatever measures were undertaken should be directed toward assisting the people to meet their needs with regard to medical service where these needs press most heavily. The government's proposal of a free general practitioner service provides the one item of medical service to which the people now have the most ready access. It omits the very things—in particular the laboratory and specialist services—which are more difficult to obtain and are essential for the accuracy of diagnosis necessary for the efficiency of the general practitioners' services. The principle of offering assistance to those who cannot fully provide for themselves has been adopted in the pensions scheme, and it is difficult to see why the same principle has not been adopted in the proposal for health insurance. It would appear that in this respect the government's proposals are based on an enthusiasm for a polysocial ideal rather than on the real health requirements of the people.

The extent to which the proposed general practitioner service differed from the treatment that the New Zealand public was accustomed to expect from the family doctor, the necessity for the inclusion of specialists in the scheme, and the failure of the government to consider adequately the whole question of health administration were points discussed by Dr. Lawrence Ludbrook, who for the past three years has represented the Auckland division of the British Medical Association on health insurance matters. In England the contract of the general practitioner in the insurance scheme is to provide, in effect, such medical advice and treatment as could reasonably be expected from general practitioners as a class. In New Zealand the practitioner provides a service, particularly in the country districts, which is much more comprehensive. It is regarded as part of his daily task to set fractures, perform operations of technical skill and undertake a wide range of the medical and surgical needs of the community. The insurance service is to be available to every member of the community, whether he is a millionaire or a pauper. The British Medical Association considers that there is a considerable proportion of the population which is able and which would prefer to provide a complete service themselves, while others in the more serious calamities of illness are at a disadvantage through lack of free specialist facilities.

It is felt that if finance is limited it would be of much greater benefit to provide a complete scheme for the smaller number of people in the lower income groups, thus enabling them to get general and special attention, than to introduce incomplete proposals covering the whole population. Dr. Ludbrook considers that the general practitioner service in Great Britain has proved to be inadequate, and for twenty-five years attempts have been made to introduce a system of specialist treatment only to find it impossible to catch up with finances. Fears for the standard of attainment and ability on the part of the general practitioner under this system were expressed. There would be little incentive for him to qualify for special work not required by the contracts. With no part for specialists in the insurance scheme and with hospital treatment provided, the increase in the number of patients in the institutions will be enormous, but the government has not yet indicated that there will be any alteration in the present methods of maintenance. In the opinion of medical men, hospitals could be made more

efficient and costs could be reduced by the provision in the home of general practitioners' and nursing services.

Another problem arises in the large proportion of the population living in country districts. Here the question of mileage is involved, and it appears that the cost of providing medical attention in the dominion is going to be much greater than in other more closely settled countries. New Zealand provides a large amount of hospital service, but there is no doubt that the system is susceptible of a great deal of improvement, the small country hospitals often being uneconomical and inefficient. It is considered that there was need for a much better coordinated system, but the government had failed to investigate this phase of health administration which, in the opinion of the British Medical Association, was of the utmost importance. A comprehensive long range plan should be drawn up instead of introducing only one aspect at tremendous cost. A general practitioner scheme was merely complementary to other equally important forms of health administration. These should have been given due consideration by an independent and, if possible, nonpolitical body.

PROBABLE COST

It is learned on authority that the increased pensions and the institution of the proposed free health service are likely to cost in the aggregate £16,000,000 annually. The revenue from the wages tax at 1 shilling in the pound is expected to be in the vicinity of £6,000,000, and this will leave a discrepancy of at least £10,000,000, which will require rather more than the pound for pound subsidy mentioned in the government's plan. In the final analysis the pensions and benefits will be paid not by the government but out of the earnings of the able bodied. They are to be taxed at the rate of 2 shillings in the pound (1/- by direct and 1/- by general taxation) for the whole of their working lives, in order to provide for the sick and the indigent. It is considered in New Zealand that one tenth of earnings is a high price to pay for social security, especially for those who keep good health and are successful in their work and who may never get anything in return for their sacrifice but the thought that they have helped those less fortunate. In any case the soundness of the social security scheme will not depend on the government but on the ability and the will of the fit to provide for the unfit and the aged. In New Zealand, at the present time, social security is being narrowed in two ways: first by reducing the demands on the able bodied and second by reduction in their numbers. The government is shortening the working life of the people by raising the school age and reducing the pension age. At the same time the forty hour week decreases their productive activities. The effect in the aggregate must be considerable. If only one end of the calculation is taken, the reduction to 60 years of the pensionable age for men will next year permit about 28,000 to retire on pension. Perhaps 20,000 will be eligible and accept the chance. So 20,000 will be removed from the ranks of the earners and taxpayers to the ranks of the pensioners, already over 100,000 strong in a population of about 1,000,000. From now on, moreover, the numbers of those aged 20-60 will decrease steadily, while the number of those over 60 will increase steadily, owing to the combined effect of the low birth rate and the low death rate. Eighteen years from now there will be 20,000 fewer persons in New Zealand aged 20-24 available for employment than there were in 1936. On the other hand, persons of 60 years of age and over increased between 1926 and 1936 by 50,304 and now comprise more than one in ten of the total population. If persons 20 years of age are to be asked to contribute 10 per cent of their income toward security many years ahead, the scheme must be expected to give security in forty years' time. At present the national income is about £145,000,000, and special and general taxation of 2/- in the pound will yield the £14,500,000 annually presumed to be necessary. But as per-

sioners increase while earners decrease, the relation might break down. There is the further question whether national income will remain at present high levels. All contingencies must be looked for and guarded against—changes in the productive powers of those who must support the rest, in the age groupings of the people, and in the economic estimation of the product of their labor.

There is a general feeling in New Zealand that the labor government, with an unparalleled enthusiasm for its cause, is introducing measures at a speed which is faster than the powers of adjustment of the community. This speed savors rather of revolution than of evolution.

The Australian Institute of Anatomy

Prior to 1924 the federal government had expressed regret that the Australian nation did not possess a collection of specimens of the unique and fast disappearing fauna of Australia. Sir Colin McKenzie, who later became the first director of the Institute of Anatomy, presented to the federal government his entire private collection. To provide accommodation for this gift, the Zoological Museum Agreement Act of 1924 provided for the formation of an Australian Institute of Anatomy and the erection of a monumental building at Canberra. In addition to the original collection, other free gifts are on view at the institute. Among them are the Horne-Bowie collection, dealing with the life of the central Australian aborigines and throwing valuable light on the psychology of this Stone Age people; the Burrell collection, which deals with the life history of the platypus and which is unique in the world (the platypus is the link between bird, reptile and mammal); the Milne collection, which is an anthropologic and ethnologic collection dealing with the aborigines of New South Wales and contains many native weapons and implements now unobtainable; the Murray Black collection of anatomic material representative of the aborigines of southern Victoria and the river Murray; the Nankivell collection, illustrating the anatomy of the aborigines of the Murray valley; the Howard University collection, which includes a collection of specimens from Harvard University, representing a carefully worked out epitome of the archeology of the United States and which, together with two rare skeletons of primitive North American Indians, was a good will gift from the university to the Institute of Anatomy; the Sir Hubert Murray collection, dealing with the anthropology of Papua; the Rabaul Ethnological collection, concerning chiefly the ethnology of the mandated territory of New Guinea, and the Basedow collection, which deals especially with the anthropology of central and northern Australia.

The Institute of Anatomy, the first unit of a National University of Australia, has already become the most important center in the southern hemisphere for the study of comparative anatomy and of its application to health and disease. The microscopic specimens of Australian fauna number thousands and are unique in the world. They represent normal mammalian tissues unaffected by disease or domestication, and with these human tissues such as those affected with cancer can be compared. The public is admitted to the two museums of osteology and applied anatomy.

Goiter in New Zealand

The Annual Report on vital statistics of New Zealand has provided evidence of the frequent occurrence of goiter in that country. Hercus and Purves have obtained information on the death rates from thyroid diseases compiled from the death certificates available from 1885 onward. A rising rate from 1889 to 1928 is clearly shown, the mean annual rate, 0.48 per 10,000 population in 1929, being more than nine times greater than the rate in 1889. The female incidence is higher than the male and varies from 3 to 10.8 per 10,000 of the population, with the exception of the period 0-5 years of age, when the male incidence is higher than the female. The average for the

whole population for all ages is 5.6. A marked rise is shown at 10-15 years and again at 20-25 years and may be ascribed to the influences of puberty and pregnancy respectively. Toxic was not separated from nontoxic goiter until 1908, when the Bertillon system of classification of deaths was adopted. Thyrotoxicosis is preponderant in the total deaths, and thyrotoxicosis death rates increase up to 70 years of age. Deaths from other diseases of the thyroid are too few for separate analysis. The admissions to public hospitals of all thyroid diseases show a striking increase from 1889 to 1933. Also the rate of increase is at present two and a half times the rate immediately after the war. The present rate is over 5.5 per 10,000 of population. Difficulties of classification in the ward make the constitution of these hospital cases difficult to determine. Exophthalmic admissions show a sharply rising rate, and for the period 1929-1933 represented 57.5 per cent of the total of all thyroid diseases. No data are available as to the distribution of nodular and diffuse nontoxic goiters. No positive correlation is observed between the incidence of goiter and malignant disease of the thyroid in New Zealand. Deaths from cancer of the thyroid are rare and not more than ten a year. Prophylactic measures against goiter have been instituted, but more complete statistical data are necessary to measure their effect.

Industrial Hygiene in Queensland

Recent legislation gave to the director general of health and medical services power to investigate the effect of conditions of work and housing on the health of employees. The director has no power to remedy any defects himself, but he may report them to the department or to the governor in council, so that legislative action may be taken. At the same time the state health department was given control of medical and dental services in schools. This should improve the service for outlying centers, as doctors attached to district hospitals will be able to assist. Restrictions relating to the use of lead paint were extended and power was given to health inspectors to take samples of paint for analysis from any building.

BELGIUM

(From Our Regular Correspondent)

April 23, 1938.

The Health of Adolescent Workers

M. Silvert has published in *Indépendance belge* a review of the medical survey of industrial conditions with special reference to the health of apprentices in the industrial training schools. The survey was started in September 1936 and included 1,774 boys and 484 girls from the urban areas of Brussels, Ghent and Liège. These youths were preparing themselves to be metallurgists, electricians, accountants, dressmakers and so on. Deplorable conditions were brought to light. In one workroom occupied by female apprentices, eighty-one different pathologic defects were observed among eighty of the girls. The most common defects determined were scolioses and the sequels of rickets (forty-one cases), defective vision (ten cases), not to speak of dental caries (sixteen cases) and subnormal body weight (fourteen cases). There was one case of tuberculosis. In a machine shop training school there were seventy-five boy apprentices from 12 to 15 years of age, thirty of whom were of delicate constitution. Moreover, thirty-three boys were affected with scolioses and the sequels of rickets, ten had visual disturbances, and there were thirty-seven miscellaneous defects. The investigators arrived at several conclusions. They declare that "medical supervision of youthful apprentices has been proved indispensable not only from the standpoint of detection of disease but from the standpoint of vocational guidance. The importance of medical examination cannot be exaggerated, for on the contraindications depend all further decisions with respect to which occupation is to be recommended or disapproved." The authors deprecate the present system under

which applicants for admission are not required to have any medical examination whatever and the degree of physical maturity of a pupil is given no consideration. Children 12 years of age and over are admitted to these schools but in most instances this age is too young. Besides, the courses are very exacting. In the technical school at Liège, with its pathetic list of debilitated pupils, the program is based on forty-five school hours a week. Half of this time is devoted to practical courses, which imply that the boy is kept on his feet at work. The schedule is unrelieved by periods of rest or recreation and no course in physical education is offered. For healthy youngsters of 16 years the regimen would be harsh, but to submit 12 year old children, most of them delicate, to such a routine is almost criminal. There are 137 vocational training schools for boys and ninety-seven such schools for girls in Belgium with a total pupil population around 29,000 (21,000 boys and 8,000 girls).

Dr. Peremans, the author of a special report, believes that medical supervision of these schools is of the utmost importance. A suitable service could be assured by the appointment of five full time medical inspectors who would examine thirty children daily for the forty weeks of five days each in the school year. This plan has one disadvantage. It would tend to limit the activities of the school doctors, who, as a consequence, would lose contact with other aspects of industrial medicine. Dr. Peremans therefore suggests that medical supervision of industry in general should be reorganized on a larger scale.

The trade schools are already amenable to a certain amount of medical supervision, such as it is, and a number of sick apprentices have been detected. The last annual report mentions 2,813 cases of various disorders, among which scolioses and the sequels of rickets loom largest (686 cases), followed by debility and anemia (502 cases). Among male youths of all groups who submitted to medical examination, defects were present in about 10 per cent. The corresponding figure for industrial apprentices is more than 30 per cent. Among 28,199 young apprentices of both sexes, 8,725 defects were found on examination. Bad teeth and enlarged tonsils, to be sure, account for an extremely large proportion of the anomalies, but the commonness of these defects does not mean that they are to be neglected. Apart from 3,000 instances of defective teeth or tonsils, debility or anemia was present in 788 instances, defects of visual apparatus in 1,388 and defects of the osseous skeleton in 519. The results of these several investigations are disquieting. They verify the data furnished by army recruiting boards and the exceedingly inadequate services of school medical supervision. The younger generation is suffering, more profoundly than one unacquainted with the facts would believe possible, from the aftermath of four years of war and five years of economic depression.

The Future of the Profession in Belgium

The commission for study of the overcrowding of the universities and the unemployment of educated persons has published its second general report. In the entire kingdom in the year 1913 there were 4,426 physicians, or one physician to each 1,726 inhabitants; in 1930 there were 5,546 physicians, or one to each 1,459 inhabitants; in 1935 there were 6,311 physicians, or one to each 1,315 inhabitants. The increase has been greatest in Brabant; namely, from one doctor to 1,197 inhabitants in 1913 to one to 938 inhabitants in 1935. On the other hand, in Limbourg province, which has the fewest physicians, the number increased from ninety-three doctors in 1913 to 174 doctors in 1935, or from one doctor to 3,109 inhabitants in 1913 to one doctor to 2,285 inhabitants in 1935.

Overcrowding of the profession is essentially due to the large number of men who wish to practice in the urban areas. On Dec. 31, 1936, there were in Brussels and environs 1,379 physi-

cians, or one physician to every 653 inhabitants; in Antwerp and environs 456 physicians, or one to every 1,068 inhabitants; in Liège and environs 416 physicians, or one to every 605 inhabitants, in Ghent and environs 242 physicians, or one to every 889 inhabitants.

The situation of the medical profession is not disquieting if one considers the development of social service, and a greater attention to hygiene on the part of the population as a whole. It is desirable, however, that there should be a better distribution of practitioners. It is particularly regretted that the number of colonial physicians should be inadequate and that so many newly graduated doctors forego this magnificent opportunity to bestow on the native population the benefits of hygiene and medical service.

Gasoline Poisoning in the Belgian Army Air Corps

Colonel Dr. Sillevaerts has published in *Bruxelles médical* a report on cases of poisoning attributable to combustibles, among the personnel of the Aéronautique militaire belge. Such accidents have been rare. There are no cases on record prior to the official adoption, on unexplained technical grounds, of "87 octane" type gasoline. In his discussion, the author takes up cases occurring among the ground personnel in charge of the fuel service and cases occurring during flight among the flying personnel, whether the result of absorption of gasoline before combustion or from inhalation of exhaust products from the motors of planes using the inculpatated fuel. From his examination of all the data, Sillevaerts concludes that the handling of 87 octane tetraethyl gasolines in the presence of a circuit that is not hermetically closed will be followed by incipient intoxication, usually scarcely noticed, among the personnel of our gasoline depots. Minor disturbances observed (in one case a fairly severe poisoning developed) may be attributed in part to tetraethyl lead, in part to benzene poisoning. Disturbances noted during flight could be traced in part to back flow of vapors of unburned tetraethyl gasoline originating in leaks from faulty piping or from the functioning of the overflow pipes and in part to weak concentrations of carbon monoxide released in the atmosphere of the cabin. These disturbances usually appear only during aerial journeys that entail numerous and sudden changes of altitude as well as on the occasion of stunting; in other words, under circumstances which require the overflow pipes to function at full force and the engine to give off a maximum of carbon monoxide. All the tests were made on board planes that were in perfect flying condition and after the airtightness of the fire extinguishers and the soundness of the fuselage had been carefully determined.

Marriages

BERT TRUMAN BRUNDAGE, Nashville, Tenn., to Miss Mary Jo Page of McMinnville in Franklin, Ky., February 18.

DAVID SCOTT BAYER, New York, to Miss Birdella Virginia Murdock of New Haven, Conn., March 26.

PHILIP GROVER PADGETT, Bryson City, N. C., to Miss Charlene Cooper of Galveston, Texas, April 2.

WAYLAND NASH MCKENZIE, Albermarle, N. C., to Miss Alice Katherine Lacy of Richmond, in April.

DICKINSON SERGEANT PEPPER to Miss Hester Marie Laning, both of Philadelphia, April 23.

JOHN L. SCHULSKY, Springfield, Ill., to Miss Lois Stahr of Louisville, Ky., March 26.

JOHN DONALD FLYNN, Grand Rapids, Mich., to Miss Ruth E. Hess of Detroit, March 1.

JOHN WILLIAM STRAUGHAN, Warsaw, N. C., to Miss Helen Ann Ward, March 24.

HENRY BAGLEY BENSON to Miss Miriam Copeland, both of Atlanta, Ga., in April.

Deaths

Calvin Hayes Elliott ♂ Hartford, Conn.; Medico-Chirurgical College of Philadelphia, 1905; member of the New England Obstetrical and Gynecological Society; fellow of the American College of Surgeons; visiting gynecologist and obstetrician to the Hartford Hospital; visiting gynecologist to the Municipal Hospital; consulting gynecologist and obstetrician to the Bristol Hospital, Bristol, Manchester (Conn.) Memorial Hospital, Rockville (Conn.) City Hospital, New Britain (Conn.) General Hospital and the Neuro-Psychiatric Institute of the Hartford Retreat; aged 59; died, March 15, in Tucson, Ariz., of abscessed teeth, secondary anemia and nephritis.

Haim I. Davis ♂ Chicago; University of Kharkov Faculty of Medicine, Kharkov, Russia, 1891; professor of psychiatry, emeritus, University of Illinois College of Medicine; member of the Central Neuropsychiatric Association; senior attending neurologist to the Michael Reese Hospital; chief of the attending staff and formerly superintendent of the Cook County Psychopathic Hospital; consulting neurologist to the Winfield (Ill.) Sanatorium; aged 72; died, April 11, of carcinoma of the lung.

William Harrison Leffler, Fountain Springs, Pa.; Medico-Chirurgical College of Philadelphia, 1907; served during the World War; for several years served on the staff of the Veterans Administration in Philadelphia, in Pittsburgh and in Newington, Conn.; aged 58; died, April 23, in the Veterans Administration Facility, Hines, Ill., of epithelioma of the bladder.

James Valentine Clarken, Baltimore; Baltimore Medical College, 1908; member of the Medical and Chirurgical Faculty of Maryland; at various times on the staffs of the Bon Secours, South Baltimore General, St. Agnes', Mercy and St. Joseph's hospitals and the Church Home and Infirmary; aged 51; died, April 17, of coronary thrombosis.

Robert Jackson Cabeen ♂ Leon, Kan.; University Medical College of Kansas City, Mo., 1903; past president of the Butler County Medical Society; part time county health officer for several years; member of the school board and mayor; aged 61; died, April 23, of cerebral hemorrhage, while playing golf at Glencoe, Ill.

Max Cohn, Chicago; Schlesische-Friedrich-Wilhelms-Universität Medizinische Fakultät, Breslau, Prussia, Germany, 1900; director of the department of radiology, Mount Sinai Hospital; aged 62; died, May 26, of suppurative pyonephrosis, diabetes mellitus, hypertrophy and abscess of the prostate.

Edmund B. Parsons ♂ Palestine, Texas; Tulane University of Louisiana Medical Department, New Orleans, 1885; fellow of the American College of Surgeons; on the staff of the Misouri Pacific Lines Hospital; aged 73; died, March 13, in a hospital at Houston of carcinoma of the sigmoid.

Herbert Morgan Decker, Davenport, Iowa; State University of Iowa College of Medicine, Iowa City, 1906; member of the Iowa State Medical Society; served during the World War; formerly a dentist; aged 60; died, April 21, in the Veterans Administration Facility, Minneapolis.

William Curtis Caywood, Winchester, Ky.; Kentucky School of Medicine, Louisville, 1906; member of the Kentucky State Medical Association; past president of the Clark County Medical Society; served during the World War; aged 60; died, April 13, of cerebral hemorrhage.

William Guy Pittman, Pine Bluff, Ark.; University of Louisville (Ky.) Medical Department, 1909; member of the Arkansas Medical Society; aged 56; died, March 16, in the Baptist Hospital, Memphis, Tenn., of chronic glomerular nephritis and malignant hypertension.

James L. Bolt, Easley, S. C.; Baltimore Medical College, 1895; member of the South Carolina Medical Association; past president and secretary of the Pickens County Medical Society; at one time member of the state legislature; aged 65; died, April 11, of coronary thrombosis.

George Herbert Mathewson, Montreal, Que., Canada; McGill University Faculty of Medicine, Montreal, 1894; formerly clinical professor of ophthalmology at his alma mater; for many years on the staff of the Montreal General Hospital; aged 68; died, March 18.

Robert James Kemper, Indianapolis; Indiana University School of Medicine, Indianapolis, 1908; member of the Indiana State Medical Association; aged 58; on the staffs of the Methodist Hospital, City Hospital and St. Vincent's Hospital, where he died, April 3.

William Wallace Russell, San Diego, Calif.; St. Louis University School of Medicine, 1916; member of the California Medical Association; served during the World War; aged 46; died, March 2, in the Mercy Hospital, of acute hemorrhagic nephritis.

Alban Judson Lobdell, Winchester, N. H.; New York Homeopathic Medical College and Hospital, 1893; member of the New Hampshire Medical Society; formerly member of the board of health; aged 69; died, March 5, in Keene, of pneumonia.

Henry Nicholas Harper, Ruston, La.; Tulane University of Louisiana Medical Department, New Orleans, 1904; parish coroner; on the staff of the Ruston-Lincoln Sanitarium; aged 58; died, April 3, of injuries received in an automobile accident.

Arthur L. Mikesell ♂ Fort Wayne, Ind.; Chicago Homeopathic Medical College, 1892; past president of the Allen County Medical Society; aged 70; on the staff of the Lutheran Hospital, where he died, April 8, of an acute gallbladder infection.

Owen Breckinridge Demaree, Frankfort, Ky.; University of Louisville Medical Department, 1891; served during the World War; aged 70; on the staff of the King's Daughters' Hospital, where he died, April 10, of bronchopneumonia.

Robert Lee James ♂ Blue Island, Ill.; Chicago Homeopathic Medical College, 1890; College of Physicians and Surgeons of Chicago, 1891; on the staff of St. Francis Hospital; aged 72; died, March 25, of sarcoma of the vertebra.

Merle Horton Whitlock, Washington, Ill.; Hahnemann Medical College and Hospital, Chicago, 1906; past president of the school board of Peoria; aged 55; died, March 29, in the Methodist Hospital, Peoria, of cerebral hemorrhage.

Robert Squair Noland, Nicholasville, Ky.; University of Louisville (Ky.) School of Medicine, 1937; intern at the Employees' Hospital of the Tennessee Coal, Iron and Railroad Company, Fairfield; aged 28; died, March 23.

Richard Herman Dingelstedt, Hoboken, N. J.; University of the City of New York Medical Department, 1895; aged 65; formerly on the staffs of St. Mary's Hospital and Christ Hospital, where he died, April 22, of heart disease.

Henry Pace ♂ Eureka Springs, Ark.; Washington University School of Medicine, St. Louis, 1903; past president of the Carroll County Medical Society; veteran of the Spanish-American War; aged 64; died, March 13.

James Francis Kelly, Hartford, Conn.; Yale University School of Medicine, New Haven, 1933; member of the Connecticut State Medical Society; aged 31; died, April 3, in St. Francis Hospital, of intracranial hemorrhage.

Richard Lionel King, Prince Albert, Sask., Canada; Trinity Medical College, Toronto, Ont., 1900; past president of the Council of the College of Physicians and Surgeons of Saskatchewan; aged 59; died, March 10.

Howard Armstrong Abraham, Oxford, N. Y.; University of Toronto Faculty of Medicine, 1906; on the staff of the New York State Woman's Relief Corps Home; aged 55; died, March 16, of heart disease.

Raymond Wesley Lagersen, Minneapolis; University of Minnesota Medical School, Minneapolis, 1923; on the staff of St. Barnabas Hospital; aged 40; died, March 13, in the University Hospital.

Frank Louis Sevanoak, Pittsfield, Mass.; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1883; aged 79; died, March 15, in the House of Mercy Hospital.

William A. Stillwagon, Kansas City, Kan.; College of Physicians and Surgeons, Medical Department Kansas City University, 1902; member of the Kansas Medical Society; aged 66; died, March 29.

Charles Lincoln Stoddard, San Diego, Calif.; Chicago Homeopathic Medical College, 1903; aged 75; died, March 15, in the Mercy Hospital, of acute dilatation of the heart following herniorrhaphy.

Henry Arthur Ulvin ♂ Milwaukee; University of Oregon Medical School, Portland, 1916; served during the World War; aged 48; died, March 31, of carbon monoxide poisoning, self administered.

Edward Monroe Jenkins, Hillsboro, Texas; Vanderbilt University School of Medicine, Nashville, Tenn., 1891; member of the State Medical Association of Texas; aged 69; died, March 27.

George Joseph Field ♂ Salt Lake City; Missouri Medical College, St. Louis, 1889; served during the World War; aged 70; died, April 23, at Rochester, Minn., of hypertrophy of the prostate.

John James Donohue, Uncasville, Conn.; Baltimore Medical College, 1909; member of the Connecticut State Medical Society; aged 80; died, April 17, of heart disease and paralysis agitans.

James Henry Moran, Chicago; Northwestern University Medical School, Chicago, 1909; on the visiting staff of St. Anne's Hospital; aged 66; died, March 2, of organic heart disease.

William O. Patton, Robbinsville, N. C.; College of Physicians and Surgeons, Baltimore, 1882; formerly member of the state legislature; aged 77; died, March 6, of cerebral hemorrhage.

Luther F. Rhodes, Abilene, Texas; Memphis (Tenn.) Hospital Medical College, 1898; formerly county health officer; aged 61; died, March 29, in Sanatorium, of pulmonary tuberculosis.

Jack Tipton Cottrell ♂ Catlettsburg, Ky.; University of Louisville School of Medicine, 1927; aged 38; died, April 1, in the Paintsville (Ky.) Hospital, of an accidental gunshot wound.

Charles Hill, Chicago; Northwestern University Medical School, Chicago, 1902; member of the Illinois State Medical Society; aged 75; died, April 11, of carcinoma of the throat.

William Carl Seale, Catchings, Miss.; Loyola University School of Medicine, Chicago, 1916; served during the World War; aged 45; died, March 30, in a hospital at Greenville.

Hermilo Mendoza, Juarez, Mexico; Universidad de Guadalajara Facultad de Medicina, Mexico, 1903; aged 63; died, April 25, following an operation for cholecystitis and nephritis.

Lewis Sydney Potter ♂ Detroit; Detroit College of Medicine, 1914; for many years on the staff of the Providence Hospital; aged 48; died, April 19, of carcinoma of the lung.

Charles Milton Storch, Biloxi, Miss.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1891; aged 67; died, March 14, of carcinoma of the prostate.

John Simon Windisch, Lakewood, Ohio; Western Reserve University Medical Department, Cleveland, 1894; also a dentist; veteran of the Spanish-American War; died, March 6.

Alphonsus J. Engel, St. Louis; St. Louis College of Physicians and Surgeons, 1899; aged 68; died, April 14, in the Missouri Baptist Hospital, of carcinoma of the pancreas.

Allan Chubb Steckle, Battle Ground, Wash.; College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1902; aged 65; died, March 5.

Joseph F. Campbell, Morristown, Tenn. (licensed in Tennessee in 1889); member of the Tennessee State Medical Association; aged 70; died, April 1, of pneumonia.

John Francis O'Brien, Canton, Ohio; Baltimore University School of Medicine, 1898; formerly on the staff of the Mercy Hospital; aged 63; died, March 7.

James Granville Mastin, Chicago; Keokuk (Ia.) Medical College, 1894; aged 80; died, March 3, in the Cook County Hospital, of arteriosclerotic heart disease.

Marie White, Pasrur, Punjab, India; Woman's Medical College of Baltimore, 1886; for many years a medical missionary; died, March 20, in Wilksburg, Pa.

Henry Elden Willdis, Cleveland; St. Louis University School of Medicine, 1937; intern at St. John's Hospital; aged 26; died, March 1, of bronchopneumonia.

William H. Byrd, El Dorado, Ark.; Memphis (Tenn.) Hospital Medical College, 1903; aged 79; died, April 3, of arthritis, heart disease and urinary suppression.

Ludovic Verner, Montreal, Canada; Laval University Medical Faculty, Montreal, 1902; Laval University Faculty of Medicine, Quebec, 1906; died in March.

Henry Howard Mather ♂ Chicago; Chicago Medical College, 1888; aged 77; died, March 11, of valvular heart disease, myocarditis and coronary occlusion.

Samuel M. Pitts, Saluda, S. C.; Medical College of the State of South Carolina, Charleston, 1886; aged 75; died, March 31, of coronary thrombosis.

L. R. Boynton, Mount Vernon, N. Y.; New York Homeopathic Medical College and Hospital, 1902; aged 68; died, March 10, of myocarditis and influenza.

Charles Clary Singley, Elmhurst, Ill.; Jefferson Medical College of Philadelphia, 1881; aged 81; died, March 17, in the Elmhurst Community Hospital.

Martin W. Dawley, Richfield Springs, N. Y.; Eclectic Medical Institute, Cincinnati, 1886; aged 77; died, March 23, of arteriosclerotic heart disease.

Sara Day Hosford Lewark ♂ Strasburg, Colo.; Colorado School of Medicine, Boulder, 1897; aged 65; died, April 8, in the Mercy Hospital, Denver.

Gordon Elliot Booth, Ottawa, Ont., Canada; McGill University Faculty of Medicine, Montreal, 1910; aged 53; died, March 6, of heart disease.

James C. Clarke, Baltimore; Hahnemann Medical College and Hospital of Philadelphia, 1888; aged 72; died, April 15, of carcinoma of the larynx.

John Jackson Farmer, Rome, Ga.; Georgia College of Eclectic Medicine and Surgery, Atlanta, 1909; aged 76; died, March 22, of carcinoma.

Charles C. Echols, Canon, Ga.; University of Georgia Medical Department, Augusta, 1900; aged 67; died in April, of cerebral hemorrhage.

Clarence Moors Golden ♂ Tyler, Minn.; St. Louis College of Physicians and Surgeons, 1906; aged 60; died, March 23, of cirrhosis of the liver.

Charles Fisher Howell, De Quincy, La.; Tulane University of Louisiana Medical Department, New Orleans, 1901; aged 66; died, March 21.

Allan James MacKinnon, Zurich, Ont., Canada; University of Toronto Faculty of Medicine, Toronto, Ont., 1908; aged 63; died, March 18.

Roy Ross Risk, Anna, Ill.; Rush Medical College, Chicago, 1930; served during the World War; aged 45; died, March 21, of angina pectoris.

Charles Murray Clayton, Indianapolis; Medical College of Indiana, Indianapolis, 1902; aged 61; died, April 1, in the Methodist Hospital.

Edward Dickson, Coal Creek, Tenn.; Medical College of Alabama, Mobile, 1882; aged 83; died, April 10, of cerebral hemorrhage.

William K. Richardson, Tompkinsville, Ky.; University of Nashville (Tenn.) Medical Department, 1877; aged 88; died, March 10.

James Lorne Graham, Ottawa, Ont., Canada; University of Toronto Faculty of Medicine, Toronto, 1909; aged 50; died, March 12.

Emily Brooke Slosson ♂ Sabetha, Kan.; Woman's Medical College of Pennsylvania, Philadelphia, 1875; aged 86; died, March 15.

Joseph Aloysius Corcoran, Montreal, Que., Canada; Trinity Medical College, Toronto, Ont., Canada, 1898; aged 59; died, March 13.

Benjamin H. Brock, Hogansville, Ga.; Southern Medical College, Atlanta, 1894; aged 70; died, April 1, of carcinoma of the liver.

Joseph L. Lalonde, Pawtucket, R. I.; School of Medicine and Surgery of Montreal, Que., Canada, 1900; died, April 6.

Roscoe Broughton ♂ Laurel, Mont.; Detroit College of Medicine, 1904; mayor; aged 55; died, April 9, of heart disease.

John Michael Crowley, Franklin, Mass.; Dartmouth Medical School, Hanover, N. H., 1897; aged 62; died, March 31.

John L. Homer, Minneapolis; University of Oklahoma School of Medicine, Oklahoma City, 1935; aged 28; died, April 8.

Duncan McEwen, Maxville, Ont., Canada; McGill University Faculty of Medicine, Montreal, 1896; died, March 23.

Robert Martin Coleman, Wellesley, Mass.; Tufts College Medical School, Boston, 1921; aged 44; died, March 24.

Leslie B. Sorrell, Waldron, Ark.; Eclectic Medical University, Kansas City, Mo., 1914; aged 50; died, March 11.

Alfred Thomas Little, Barrie, Ont., Canada; Trinity Medical College, Toronto, 1885; aged 75; died, March 29.

Gustave Charles Wichman, Glendale, Calif.; Illinois Medical College, Chicago, 1899; aged 63; died, March 28.

Eugene Merchants Brown, Boston (licensed in Massachusetts by years of practice); aged 68; died, March 28.

George B. Sharp, Piedmont, Ala.; Southern Medical College, Atlanta, 1893; aged 67; died, March 21.

R. H. Mays, Duke, Okla.; Ensworth Medical College, St. Joseph, Mo., 1906; aged 58; died, March 19.

Edward L. Webb, Los Angeles; Rush Medical College, Chicago, 1894; aged 65; died, March 10.

Samuel M. Dow, Cleveland (licensed in Ohio in 1894); aged 84; died, April 13, of pneumonia.

Correspondence

INJECTION METHOD FOR HERNIA

To the Editor:—Recent issues of the medical press have carried notices that the U. S. Employees Compensation Commission has issued an order dated Feb. 24, 1938, that the treatment of hernia by the injection method is not authorized and will not be paid for in WPA and federal employee cases. This, of course, will be taken as official government condemnation of a mode of treatment, in itself a dubious assumption of authority in matters of medical opinion, which, if followed as a precedent, is likely to hamper progress on more than this one medical front.

What is worse, this order merely makes official an attitude stubbornly held by this commission over several years, as numerous herniated federal employees know to their cost. The argument used to be that federal employees can be operated on in Navy and Army hospitals at low cost to the government, this single consideration of economy being brought forward as sufficient and decisive. All efforts to bring before the commission the favorable results now widely being secured by competent and experienced workers with the injection method have always been met by curt, ex cathedra citation of official "decisions." That several thorough modern studies and reports on an aggregate of more than 5,000 carefully traced cases today show (with one questionable exception) injection results fully comparable to those of surgery is being consistently ignored. Official opinions and decrees, it seems, are not subject to review and reconsideration.

This arbitrary attitude on the part of the compensation authorities has worked real hardship on federal employees. I can cite nineteen cases (in which there were twenty-four hernias) which have come locally under my personal care, mostly from one federal establishment. Every effort to secure federal compensation having been flatly rejected if the injection treatment was employed, these employees of the government have stayed on the job, taken this ambulatory treatment and paid for it out of their own pockets. Of the nineteen, two cases are still under treatment, all the others being cured. This group has sent a total of thirty-four patients who have taken this treatment, with a number of others who are considering it on the recommendation of members of the group. In some instances the securing of federal jobs or the getting of promotions has depended on the curing of these hernias. In every such instance the case was passed on as cured after the injection treatment, and the job or promotion secured. In other words, despite the condemnation by the compensation officialdom and their refusal to pay for the injection treatment even if effective, federal employees, on the basis of results experienced by their fellows, are choosing the injection treatment, paying for it themselves, getting cured and being pronounced cured by federal medical examiners. Whereupon prejudice, in position of authority, extends its arbitrary decision to a vast army of relief workers as well as to regular federal employees, thereby, I presume, contributing to the progress in the Works Progress Administration.

Far more enlightened and considerate is the attitude expressed in a letter just arrived from a private concern, a self insurer under the New York compensation law. It refers one of its employees for hernia treatment by the injection method and states that, though it is not responsible in this case under the compensation law, it is lending the employee the money for the treatment. But, then, this concern has had actual experience with this treatment in numerous cases over a period of years, and, besides, it has no "authority" to exercise or maintain. In this respect, at least, federal employees and relief workers are less fortunate in the fairness and intelligence of their boss.

S. W. FOWLER, M.D., New York.

TESTS FOR ALCOHOLIC INTOXICATION

To the Editor:—Referring to the letter on this subject in THE JOURNAL, April 23, page 1386, it is to be questioned whether Dr. Reinke has given indication of experience that justifies him in deprecating laboratory methods of determining intoxication.

Dr. Reinke's first point was that the personal equation of various drinkers was not sufficiently considered. He believes that the alcoholic brain concentration lethal for an infant would not have nearly so deleterious an effect on a drunkard. What has such a surmise to do with alcoholic drivers? The articles Dr. Reinke refers to did show, at least, that there are among "adults" definite levels of concentration of alcohol beyond which a state of intoxication or actual drunkenness is present. Reference was made in one of the articles to the fact that these levels were the same whether found in habitués or in occasional drinkers, since increased toleration is due to increased oxidation of the alcohol and to other less important factors which combine to rid the system of alcohol faster as toleration increases.

When the charge against a driver is such that the question of his degree of intoxication becomes important, and if any specimen, taken from him with his consent, is found to show an unquestioned state of drunkenness and testimony is so offered at trial, the defense will secure testimony from those who clinically observed the defendant at the time the specimen was taken. This testimony will of course be that they (lay witnesses or otherwise) believe the defendant to have been then drunk. The scientifically obtained testimony may then be thrown out on the ground that a drunken person cannot give valid consent (to the taking of the specimen from him). Afterward defense testimony will all too often lead to acquittal of the prisoner. However much such a state of affairs indicates needed changes of law, it has nothing to do with the science and justice of the tests in question.

ROBERT C. KEYS, M.D., Fairfield, Conn.

THE PROTECTIVE ACTION OF CERTAIN SULFANILAMIDE DERIVATIVES IN EXPERIMENTAL INFLUENZA INFECTIONS

To the Editor:—The recent report before the American Chemical Society meeting of the details of synthesis of a series of sulfanilamide derivatives by Crossley, Northey and Hultquist (Sulfanilamide Derivatives: I. Amino-Aryl-Sulfonamido-Aryl-Sulfonic Acids and Amino-Aryl-Sulfonamido-Aryl-Carboxylic Acids; II. Disulfanilamide and Related Compounds; III. Strepto-N-Polysulfanilyl-Sulfanilamides and Related Compounds, *J. Am. Chem. A.*, to be published) together with the statement that they have been found to be effective protective agents in experimental infections with influenza virus makes us feel that some of the preliminary experimental work on which these statements are based should be presented to the members of the medical profession for critical analysis.

A series of almost 100 sulfanilamide derivatives have been subjected to preliminary examination for protective action in experimental influenza virus infections. The Puerto Rico strain of human influenza virus, originally obtained from Dr. Francis of the Rockefeller Institute for Medical Research, was employed throughout the entire series. The procedure for the intranasal administration of the virus to mice has been described in detail by Francis and only the essential principles are given here. Lungs from infected mice are removed aseptically and ground up with sterile sand and saline solution. The final suspension is approximately 1:1,000; this is centrifuged and from 0.01 to 0.02 cc. administered intranasally to mice previously anesthetized with ether. Care is taken to see that all the material so administered is aspirated. The mice are of the Swiss strain, are from 4 to 6 weeks of age and weigh from 10 to 14 Gm.

Control animals so infected begin to show symptoms from the second to the seventh day following administration. The duration of the incubation period bears an inverse relationship to the quantity and virulence of the virus administered. The acute symptoms are roughened coat, apathy, evidence of fever and marked dyspnea. Death occurs from ten to seventy-two hours after the onset of acute symptoms and the most characteristic lesion post mortem is massive consolidation of both lungs. Animals do not recover after showing acute symptoms.

The first two substances examined in this series were sodium sulfanilyl-sulfanilamide, which had previously been described by A. R. Dochez and C. A. Slanetz (The Treatment of Canine Distemper with a Chemotherapeutic Agent, Sodium Sulfanilyl-Sulfanilate, *Science* 87:142 [Feb. 11] 1938) to be an effective chemotherapeutic agent in the protection of animals experimentally infected with dog distemper virus, and of sulfanilamide itself, which had been described by S. M. Rosenthal, J. G. Wooley and Hugo Bauer (The Chemotherapy of Choriomeningitis Virus Infection in Mice with Sulfonamide Compounds, *Pub. Health Rep.* 52:1211 [Sept. 3] 1937) to be effective in treating experimental choriomeningitis of mice. Neither of these substances had any effect on the course of experimental influenza infections.

Up to the present time two types of substance have been found capable of influencing the course and eventual outcome of the experimental disease. The first is disulfanilamide and is represented by three members: disulfanilamide, *N*¹-methyl-disulfanilamide, and *N*¹-ethyl-disulfanilamide, having the structural formulas:

The second type substance is represented by 2,5-bissulfanilamido-benzene-sulfonic acid, with the structural formula:

This experimental procedure was followed throughout the entire series: mice were divided into groups of tens, and after infection treated according to the following scheme:

Group A. Untreated controls.

Group B. Ten mg. of drug (subcutaneously) at one, twenty-four, forty-eight and seventy-two hours after infection.

Group C. Ten mg. of drug (subcutaneously) at twenty-four, forty-eight and seventy-two hours after infection.

Group D. Ten mg. of drug (subcutaneously) at forty-eight and seventy-two hours after infection.

Group E. Ten mg. of drug (subcutaneously) at seventy-two hours after infection.

It was found that all the drugs described in this paper were capable of protecting infected animals provided a moderate infecting dose of the virus was administered; that is, when the infecting dose was of such an order as to produce acute symptoms after an incubation period of at least four days. When the infecting dose was increased to the point at which the control groups showed acute symptoms by the second or third day after infection, with the majority of deaths on the third or fourth day, the drugs were completely ineffective. This is illustrated in the accompanying protocols. The key letters of the groups

are the same as those already described. Disulfanilamide was employed in both of these experiments. In the first instance a moderate infecting dose was administered, while in the second series a much stronger infecting dose was administered.

SERIES 1.—Moderate Infecting Dose

Group	Percentage Mortality on				
	3d Day	6th Day	9th Day	12th Day	15th Day
A	0	80	100	10	10
B	0	0	0	0	0
C	0	0	10	10	10
D	0	20	30	30	30
E	0	30	50	70	70

SERIES 2.—Strong Infecting Dose

Group	Percentage Mortality on				
	3d Day	6th Day	9th Day	12th Day	15th Day
A	90	100	10
B	80	90	100
C	90	100	10
D	100	100	10
E	90	100	10

The differences in activity of the substances described here are small. The protocols which are given for disulfanilamide are almost identical with those for the other substances and will be published in detail in the near future.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

REMOVAL OF TATTOO MARKS

To the Editor:—Please advise me as to the methods of removing tattoo marks.

LEON A. FRANKEL, M.D., Philadelphia.

ANSWER.—Tattoo marks are of two kinds, intentional, supposedly decorative, and accidental, from powder explosions, falling in cinders and similar accidents. In all of them the pigment is deposited in the corium, deeper in the accidental than in the intentional cases, and therefore more difficult to remove. Many different processes have been used:

1. Rubbing the skin is said to remove tattoo marks when it is done persistently. Janson (Eine einfache Methode der Entfernung von Tätowierungen, *Dermat. Wchnschr.* 101:894 [July 20] 1935) anesthetizes with procaine and epinephrine and then rubs the skin of the mark with a stiff brush until it bleeds. He then applies an ointment of 2 per cent anesthesin in zinc oxide ointment. The treatment must be repeated a number of times. On the skin of the trunk or arm it is satisfactory but not on the hand or fingers. G. H. Klövekorn (*ibid.* 101:1271 [Oct. 12] 1935) substantiates Janson's assertions.

2. Fahlbusch and Holtz (Eine neue Methode zur Entfernung von Tätowierungen, *München. med. Wchnschr.* 83:1598 [Sept. 25] 1936) use live steam from an inhalation kettle carried by a rubber tube with a glass nozzle to the area to be treated. The skin is cleansed with ether and alcohol, then anesthetized with procaine and epinephrine, and the borders of the area protected with zinc paste, a proper margin being allowed beyond the visible border of the mark. After the steam has been applied for a few seconds, the epidermis can be rubbed off, exposing the cutis and the pigment particles. The steam is kept on this until it turns white; then a burn liniment is applied and internal sedatives are given to alleviate the pain after the effect of the

local anesthetic has worn off. After twenty-four hours the wound is dressed with a bland ointment, and in from two to six days the pigment may be brushed off or picked out of the wound with little pain. The patient can return to work after three days. The scar is thin and soft. No infection occurs if ordinary surgical care is used, for the steam disinfects the wound.

3. Thurn (Narbenlose Entfernung von Tätatuerungen, *Med. Klin.* 33:1134 [Aug. 20] 1937) advocates the use of salicylic collodion applied until the area oozes, then pressing in fine salt crystals. This causes sharp pain for from twenty to thirty seconds. Local anesthesia may be necessary. Dry dressings are applied, which, with the crust, must be removed on the third day, bringing with it the pigment. The epithelium is restored in from six to eight days. One treatment is usually enough, but repetition is sometimes necessary.

Others use pyrogallic plaster, carbon dioxide snow, digestives, ultraviolet rays or tattoo in a skin colored enamel to cover the marks. Karpelis, who seems to have had experience, disapproves of these methods (Ueber Entfernung von Tätatuerungen, *München. med. Wchnschr.* 84:529 [April 2] 1937) and the use of electrolysis but favors surgical excision for small marks and the galvanocautery for the larger ones. With this he shells off the epidermis and then attacks the pigment, which thus has become visible. He is careful to treat 1 or 2 mm. beyond the border of the mark to ensure getting it all. The cold cautery he values much less. He also favors the method of cross hatching the skin fairly deeply with a scalpel, stoppage of bleeding and then rubbing in finely pulverized potassium permanganate. A dry dressing is then applied.

The most popular method of all and one that is still approved by experts is that of Variot. A 50 per cent solution of tannic acid is tattooed into the mark just deep enough to avoid any considerable bleeding. Then the silver nitrate pencil is rubbed over this area until it becomes black. The black crust separates in about sixteen days. If the mark is an accidental one and particles of carbon remain, the crust should be removed earlier and the remaining particles of pigment curetted out. M. D. Shie (A Study of Tattooing and Methods of Its Removal, *THE JOURNAL*, Jan. 14, 1928, p. 94) recommends anesthesia with procaine and epinephrine when the mark is on the face or ears to control bleeding, which interferes with the penetration of the tannic acid solution. The pain is so slight when the tattooing is done rapidly that it is inconsequential.

For discrete carbon particles, H. C. L. Lindsay (Surgical Removal of Powder Tattoo, *THE JOURNAL*, Nov. 6, 1937, p. 1530) recommends excision of each blue point with a cataract knife. Suturing is seldom necessary if the operator is careful to make small wounds. Another surgical method is to loosen a flap containing the whole tattoo mark, turn it over and pick out the pigment, then right it and suture it in place.

Like many other procedures for which many methods are used, the best results are obtained by becoming expert in a few of the methods and choosing carefully the one best suited to the case in hand.

VISCEROPTOSIS

To the Editor:—A woman, aged 30, shows roentgenographic evidence of colon and stomach ptosis. She has constipation and dragging pain in the umbilicus. Will a surgical belt or support of any kind aid the patient?

ROBERT D. KANE, M.D., Elmhurst, N. Y.

ANSWER.—The treatment of gastro-enteroptosis is best outlined by consideration of the various types that occur. A. P. Cawadias has mentioned three: 1. The well known Stiller syndrome, which is constitutional and is synonymous with an asthenic constitution and a microsplanchnic hypovegetative constitution (Pende). These individuals have a long narrow thorax, there is a general scarcity of fat, and x-ray examination shows a general enteroptosis including elongation of the stomach, colon and kidneys. Psychologically these patients tend to be introverts. 2. The neurotic type, in which the symptom complex comprises headaches, insomnia, depression and a general anxiety about their condition. These patients are prone to believe that they have a serious abdominal disease and to restrict their diet, thus creating a vicious circle, the resulting loss of weight further increasing the visceroptosis. 3. Rarely, gastro-enteroptosis characterized by pain which is not relieved by the horizontal position. This is due to perivisceritis and follows some primary inflammation. The treatment depends on attacking the underlying cause.

Goldthwait has shown that in many individuals there is a definite sagging of the diaphragm and lower ribs. Improvement in these patients, he says, can be obtained only by the use of corrective exercise. In connection with the remodeling of the body, jackets are often of help. These should include some definite support to the back. Belts and supports are of

relatively little value unless accompanied by other forms of treatment. Diet is of vast importance and when a good increase in weight can be obtained the results are almost invariably good. Exercise, both in the lying and in the erect position, is an essential part of therapy. The use of belts should be considered as only an accessory in the treatment. Psychotherapy may accomplish more than any other one measure in the neurotic type. It should be remembered that there are a great many patients with extreme visceroptosis who are symptom free and it is a mistake to emphasize low-lying organs found accidentally or incidentally by x-ray examination.

TINNITUS AURIUM

To the Editor:—A woman, aged 55, complains bitterly of a roaring and buzzing noise in the head which makes her feel as if the whole body were throbbing and affects her sleep. She thinks the condition is affected by taking salt or sugar. She has had this trouble for five years. The menopause began in June 1930 and was complete by February 1934. With the terrific roaring in the head she is exceedingly nervous and often has insomnia. The nurse can tell from her appearance when an attack is about to come. A severe attack lasts several days but she is rarely free from all the noise. Sometimes with it there is twitching of the face muscles of mild degree. The roaring has increased during the last three years. With an attack the pulse rate goes from 74-80 to 100-110 and she becomes alarmed. Sometimes it awakens her from a sound sleep. She has been treated since 1927 for pulmonary tuberculosis, which is but slightly active today. In 1931 she had at one time a blood pressure as high as 200/110 and the same year it fell to 130/80, which is approximately the pressure she has maintained since then. I have tried theelin, emmenin, a low salt diet and ergotamin without benefit. There have been several phases of "nervous breakdown" during these ten years. The urino is normal. Inflation of the eustachian tube for a mild catarrhal condition led to no benefit. Suggestions for treatment would be appreciated.

M.D., New York.

ANSWER.—Most cases of tinnitus are subjective in character. There are, however, unusual occasions in which the noise may be demonstrated to an observer. Head noises may arise from conditions within the ear and in the immediate neighborhood of the ear. In practice the most persistent and annoying forms of tinnitus are usually seen in connection with disease of the internal ear and its central pathways. Tinnitus due to conditions within the external auditory canal and the middle ear are apt to be much less annoying and much more amenable to treatment. In the neighborhood of the ear transmitted noises from arteries, veins or aneurysms are occasionally observed. The use of drugs such as acetylsalicylic acid may produce tinnitus without apparently any permanent or demonstrable effect on the hearing.

The description of the sounds varies from low, rushing, murmuring sounds usually assigned to disease in the middle ear to high pitched, hissing, whistling, ringing noises generally thought to be due to difficulties in the internal ear. From this type of head noise to a type characterized by distinct musical character is only a short step. Such noises may be designed as whistling, ringing, bell-like in character. One step further carries one into the realm of noises that begin to partake of hallucinations. A patient will say that an old melody recurs over and over again; perhaps some song not heard since early childhood. The last step is, of course, distinctly hallucinatory in character. Voices and other sounds are heard and associated with mental disturbances of a profound character.

Again it is not easy to say how much the so-called nervous constitution has to do with these noises. Certainly, a persistent tinnitus may make the most self-contained person nervous and, on the other hand, it should not surprise any one that the highly strung person would be apt to exaggerate the distress he experiences.

It is therefore plain that the patient's description of the noises and the degree of reaction to them must in some measure be related to the nature and location of the disease area as well as be influenced by the temperament of the sick person. The patient is of a nervous character. Her complaint, with its intermissions, is such that it could be due to some disturbance in the end organ of hearing and its central pathways. She also has had a hypertension and, while the blood pressure is lower now than it was, there still may be changes of a vascular character in the brain sufficient to produce the symptoms. There is no statement made as to the absence or presence of a hearing defect. The presence of a hearing defect, especially a severe one, might help to locate the lesion in the cochlea. It is just such deafness of an auditory nerve type that produces tinnitus of the more severe and persistent kind. From time to time also tinnitus of a stubborn and troublesome character may precede by many years the onset of such a deafness.

Experience states that treatment of the type of tinnitus described is apt to be without benefit. Psychotherapy, encour-

agement of the patient to accept her condition with as much philosophy as possible, and the avoidance of fatigue and nervous strain as well as the use of mild sedatives are all indicated. As much as possible one should attempt to discover the cause and by so doing influence for the better this most aggravating complaint.

POSSIBLE ANOREXIA NERVOSA

To the Editor.—A woman, aged 34, an executive in a college, has a usual weight of from 130 to 140 pounds (59 to 63.5 Kg.); her highest weight was 160 pounds (72.6 Kg.) in 1927. Her menses began at 16 and occurred from two to four times a year until 1933, lasting four to five days. In 1932 she began to lose weight, the greatest loss occurring from December 1934 to March 1936, at which time it reached 86 pounds (39 Kg.). Constipation has always been severe. Cathartics have been taken in large amounts and many stools daily resulted. Epigastric distress and flatulence prevented the usual diet and from 1934 to 1936 it was limited to fruits and vegetables. In 1932, swelling of the face, thighs and legs, without pitting, developed. She felt heat excessively and could not stand a warm room. There was palpitation on exertion. When in March 1936 her weight reached 86, she was studied in a hospital. There was no fever. The blood pressure was 100 systolic, 60 diastolic. General examination was negative except for wrinkling of the skin of the legs, as if from edema. Laboratory work failed to reveal any evidence of organic disease. The urine was normal, the blood urea nitrogen 7, total blood protein 5.8, albumin 4.2, globulin 1.5, metabolic rate minus 20, cholesterol 289, red blood cells 4.7 million, hemoglobin 100 per cent and white blood cells 15,700. Five days later after she had gained 10 pounds (4.5 Kg.) the red blood cell count was 4.0 million, hemoglobin 80 per cent, white blood cells 9,300. A chest roentgenogram was negative. The skull roentgenogram showed a normal sella turcica, and the optic fields and the fundi were normal. The stools were normal and x-ray examination of the gastro-intestinal tract gave negative results. The diagnosis lay between malnutrition from dietary restriction and Simmonds' syndrome. Accordingly the patient was given a 3,500 calory diet with added vitamins and 4,000 cc. of fluids. Within two months her weight had risen to 130 pounds (59 Kg.), which was held to April 1937. Her complaints were not relieved, however, as she continued to feel heat and itching in her face and tightness of the thighs, although no swelling was evident, and the stools were loose, whether frequent or infrequent. No menstruation had occurred since 1933. It was thought advisable to try endocrine therapy, and injections of the gonadotropic factor from the urine of pregnancy and anterior pituitary extract were given, a total of 40 cc. in 1937. Menstruation occurred three times, in May, June and July. She improved subjectively during the spring and summer, but in the fall began to feel bad generally, did not feel like eating, tired easily, and acquired edema of the face and extremities. The output of urine was low, a pint or less daily. Ammonium chloride from 60 to 90 grains (4 to 6 Gm.) daily caused some increase in output with improvement in symptoms, but its effect seemed to wear off and salyrgan was used a few times at weekly intervals with benefit. The urine was normal, as was the general examination. The bowels were moving five times daily with cathartics, and there was a good deal of flatulence. She was unable to do without cathartics. Enemas were without effect. Her weight now (December 1937) is 117 pounds (53 Kg.). What diagnostic possibilities are there? What further studies should be made to clarify the diagnosis? What therapy is indicated? Should she be put to bed with high calory feeding as was done in 1936, thereby sacrificing her position? Should endocrine therapy be continued, possibly in greater amounts? Thyroid extract was first used in 1934. She was intolerant to even one-tenth grain (0.0065 Gm.) three times a day.

M.D., New Jersey.

ANSWER.—The clinical syndrome described appears to be due to dietary restriction or, if one prefers the term, "anorexia nervosa." Simmonds' disease, which depends on actual destruction of the anterior lobe of the hypophysis, for all practical purposes, is excluded from consideration by the long history associated with the case and by the absence of any objective evidence of hypophysial involvement. Anorexia nervosa, while usually regarded as a functional disorder, manifests itself at times in a manner suggestive of a physiologic disturbance of the anterior lobe of the hypophysis, with subsequent failure to provide thyrotropic and gonadotropic substances in normal amounts. The multiplicity of bizarre symptoms mentioned by this patient is not unusual in cases of anorexia nervosa and appears to depend on the existence of an unstable nervous constitution.

Further diagnostic studies might include repeated determinations of the basal metabolic rate and of the concentration of cholesterol of the blood as well as examination of the deep reflexes. The history of edema is somewhat suggestive of the presence of atypical or mild myxedema. If an actual deficiency of the thyroid gland is present, some sluggishness of the reflexes may be demonstrated (Chaney, W. C.: Tendon Reflexes in Myxedema, *THE JOURNAL*, June 21, 1924, p. 2013). It may be noted parenthetically that edema of dependent parts is sometimes encountered in cases of anorexia nervosa for reasons that are not entirely clear; possible qualitative alterations of the proteins of the plasma and reduction in the colloidal osmotic pressure of the serum have been suggested as explanations. The presence of irritability of the bowel suggests two possibilities for investigation: search for parasites in the stool and examination of the gastric juice, for anacidity is commonly

encountered in cases of anorexia nervosa. If the stools contain more than the normal amount of fat the possibility of the presence of pancreatic disease must be considered; in particular, studies of the enzymatic activity of the contents of the duodenum should help to determine this.

Assuming that all organic disturbances can be eliminated from consideration and that the diagnosis of anorexia nervosa can be established, treatment is most difficult. The best results, as a rule, are obtained by prolonged rest in bed, by psychotherapy, by forced feeding and by elevation of the basal metabolic rate. Use of thyroid extract should be persisted in even if mild signs of intolerance are noted when its administration is begun and an attempt should be made to maintain the basal metabolic rate at a level of about —5 per cent. Use of insulin to increase appetite and food intake is helpful in certain instances. Avoidance of laxatives, assurance of an adequate intake of food and an ample supply of vitamins or of protein and of bulky foods should contribute to increase in weight and strength and to amelioration of the constipation and irritability of the bowel. The menstrual cycle often is restored by this treatment alone and, as a rule, it is well to forego the use of such preparations as gonadotropic substance and extract of the anterior lobe of the pituitary gland until the basal metabolic rate and the body are restored to normal. Relapses are to be expected and their occurrence does not imply necessarily that either diagnostic or therapeutic errors have been made.

DANGERS OF PARAFFIN

To the Editor.—What are the dangers and uses of paraffin? The paraffin is melted and put through a mechanical spray under two pounds of pressure, which causes the paraffin to leave the machine in a powder form. The room measures approximately 20 by 18 feet and is ventilated by a suction fan. The worker is supplied with a small mask with a cloth ventilator but states that this mask is unsatisfactory in use. Isn't it true that there is considerable danger in breathing the air in a room where paraffin is mixed with the air? What type of mask would be most satisfactory to use for this work?

M.D., West Virginia.

ANSWER.—Pure paraffin wax is widely regarded as non-toxic, but possibly it may possess some carcinogenic properties. The misuse of paraffin in cosmetic surgery has been associated with paraffinomas. Work around molten paraffin, particularly if the paraffin is overheated, is more uncomfortable and nauseating than dangerous and is important because of associated distaste for food and possible resulting malnutrition. R. Prosser White (The Dermatogoses or Occupational Affections of the Skin, London, H. K. Lewis & Co., 1934) has reported that in a group of women and girls long employed under conditions in which they were literally bedaubed with paraffin wax during their work, none experienced the least inconvenience or distress, either internally or externally. Bridge, whom White cites, has found no evidence of skin disorder among paraffin candle makers. Liquid petrolatum or wax taken internally or applied to the skin rarely has proved detrimental, although the use of liquid petrolatum in constipation has been associated with eczema ani; but here mechanical abrading may constitute a factor (Gibson, Robert: Risk of Liquid Paraffin in Chronic Constipations, *Brit. M. J.* 1:876 [May 14] 1927).

In industry, paraffin oils and closely related petroleum derivatives have been associated with industrial dermatoses, acne, furunculosis and possibly tar cancer. However, it seems possible to demarcate for toxicologic purposes pure, solid paraffin and at least some of the paraffin oils.

In the printing industry the paraffin spray is sometimes used as a rapid drier for ink. It has been reported that paraffin dust or flakes ball up in the respiratory passages and may be coughed up or blown out of the upper respiratory areas. The best solution to this problem is to be found in a local exhaust system rather than in general room ventilation. A suitable small appliance may be designed to entrap all the extraneous paraffin dust. The wearing of ordinary masks or respirators is not entirely satisfactory, since the waxy nature of the paraffin tends to seal off the filtering surface of the mask to an extent greater than ordinary dust. Thus breathing is hampered and workers may decline to wear a mask of the type that actually serves as a filtering medium. It may prove desirable to provide the worker or workers with a light type of positive pressure respirator, which continually furnishes respirable air from a suitable source remote to the contaminated workroom atmosphere. Many types of respirators are available through commercial sources, some of which are recognized as suitable by the United States Public Health Service or by the Bureau of Mines.

MAKING OF FOOTPRINTS

To the Editor:—To obtain footprints, the old fashioned method is still mostly used, of having the patient stain his sole on an ink pad and step on a paper. This method gives a good picture but has the disadvantage of soiling the foot with ink and, therefore, it cannot be used in cases of ulcers or sore spots. When I saw the method of fingerprinting used in the postoffice (put the finger on a glass plate covered with some fat or paraffin and then on a piece of paper which is afterward stained with a developing fluid, resulting in a nice picture without marring the patient's skin) I thought that this method could also be used for footprinting. On the suggestion of the postmaster I wrote to the Postmaster General's Department in Washington for the formula of the developer and also the kind of fat used but received the answer that it is not permissible to render such information. When I wrote to the Bureau of Investigation in Washington, Mr. Hoover answered that he could not give me the formula but that I should communicate with the Faurot Identification System in New York. This company, however, did not give me the formula, which, it said, is antiquated, but recommended its own product. On further investigation I found that a German manufacturer of chemical products, I. G. Farbenindustrie A. G., sells a developer for this purpose; its formula also is secret. For the sake of completeness Freiberg's method has to be mentioned of staining the foot with a solution of tannic acid and then the paper with ferric chloride; the compound is ink, and a black but not clear picture is obtained. Now I am wondering whether you would be able to find the formula of the developer for printing, with the method of staining with petrolatum or fat. I think that not in medical literature, but in criminalistic books on dactyloscopy more information can be found. I am not in a hurry to get this information, so please take your time.

M.D., Illinois.

ANSWER:—There appears to be no publication which gives information on the newer methods of taking fingerprints and footprints. On the whole, the ink method has been the most satisfactory. Chemical formulas are used by a number of police departments; our correspondent believes that a formula may be found that will leave an imprint where there is the greatest pressure. Certain parts of the foot may produce a greater amount of secretion than other parts, and the print at that point would be heaviest; that is, the pressure itself would have much to do with it. Therefore it is difficult to see why there would not be just as much success with the ink method as with some of the "chemical formula" preparations on the market, the exact compositions of which have not been divulged.

The method known as the Faurot method consists of a specially treated paper, which is used with a chemical pad that presumably does not leave a stain or discolor the skin.

Another method for fingerprinting or footprinting, which has been used with some success, is placing the fingers in a coating of petrolatum and the use of osmic acid fumes subsequently, which will bring out a good black print. Also in the case of petrolatum, Fleming's reagent fumes will bring out a very good black print or, if desired, the reagent may be used with or without petrolatum.

NECROSPERMIA

To the Editor:—What is the cause of necrospemia? What is the treatment? Can you give references to the recent literature? A young married man, in good health, wants a child. Endocrinologic and gynecologic examinations of his wife show her to be in apparently normal condition. Examination of the husband revealed nonmotile spermatozoa of a count of 96,000,000. Repeated specimens showed the same condition, even when material was collected in an aseptic, chemically clean receptacle. Injections of antuitrin-S over a period of two months have not produced any change. The pH of the semen was 7.5.

M.D., Pennsylvania.

ANSWER:—Necrospemia may be artificially induced by subjecting the condom to heat, which is often done by patients who fear that the specimen might get cold while en route to the doctor. Necrospemia is always present if the specimen is examined a long time after coitus.

One must distinguish between those cases in which the testicle produces only dead spermatozoa and those in which the spermatozoa are killed after leaving the testicles by some pathologic condition in the genito-urinary tract. In the latter condition a painstaking examination of the entire tract, including in some cases a cysto-urethroscopy, must be done. The presence of many pus cells in the expressed prostatic vesicular fluid is significant, not because pus kills spermatozoa but because it indicates that some disease is present which should be investigated. In some cases a congested prostate may be the cause, simply because the relief of the congestion cures the condition. It must be admitted however that sometimes examination, even if exhaustive, may fail to find the cause.

The Huhner test is sometimes of distinct value in such cases. Spermatozoa have been found alive in the female genitals after coitus, whereas repeated condom and other examinations have always shown only dead spermatozoa.

Testicular necrospemia may be caused by the application of x-rays to or in the neighborhood of the testicles even when a protective device had been used by the dermatologist or physical therapist.

A recent discussion of necrospemia may be found in Max Huhner's *Diagnosis and Treatment of Sexual Disorders in the Male and Female Including Sterility and Impotence*, Philadelphia, F. A. Davis Company, 1937.

OLD ULCER SCAR CAUSING NAUSEA

To the Editor:—A white woman, aged 36, complains of nausea without vomiting. She has had an appendectomy and a cholecystectomy, and six months ago a posterior gastro-enterostomy was performed for relief of partial pyloric obstruction. The cause of the obstruction as found at operation was an old ulcer scar. The nausea is apparently due to bile in the stomach, coming through the operative opening, because draining the stomach relieves the nausea. The stomach contents are chiefly bile. There is no free hydrochloric acid; the total hydrochloric acid is only 11 points. Is there any way to prevent the bile from entering the stomach? Is there any way to avoid the nauseating effect of the bile, other than intravenous administration of calcium gluconate, which has been fairly successful in this case?

R. V. BRANDON, M.D., McDonough, Ga.

ANSWER:—The case described presents many difficulties. While more surgical treatment, such as a lateral anastomosis between the afferent and efferent loops, would eliminate the reflux of bile into the stomach, it probably is unnecessary and might be followed by other untoward symptoms. Bile in the stomach is not necessarily a source of trouble. In fact, all the bile has frequently been shunted into the stomach in case of irreparable obstruction of the common duct without subsequent gastric symptoms. There is usually some reflux of bile and duodenal contents into the stomach after gastro-enterostomy. Paterson suggested that much of the virtue of the operation lay in the reduction of gastric acidity by the regurgitation of bile.

Achylia suggests that the patient is suffering from asthenia universalis, or Stiller's disease. Increasing the weight and attention to mental problems would probably accomplish more than a new operation.

SPASMS OF LEGS AT NIGHT

To the Editor:—A man, aged 62, in good general health, has occasional attacks of muscle spasms of the legs during sleep. He has never had attacks during the day. The calf of the leg, the popliteal space or the ankle is involved. On one occasion the two feet were affected at the same time. The spasm passes off spontaneously in from ten to fifteen minutes. He is a moderate smoker. The patch test for tobacco gives only slight reaction. The blood pressure is normal. Is there any contraindication to the use of tobacco? Has the condition any relation to thrombo-angiitis obliterans? What suggestions can you give for diagnosis?

M.D., New York.

ANSWER:—Since the spasms of the muscles occur at night, it is doubtful that the condition is related to thrombo-angiitis obliterans. Such symptoms are at times encountered in arteriosclerosis both of the peripheral vessels and of the spinal cord and the spinal roots. Likewise they may be the expression of tumors or inflammatory disorders of the last named structures. The possibility exists that the spasms from an unexplained increase in muscular irritability would have to be considered, in which case they should be readily relieved by mild sedatives. There would not be the same contraindication to the use of tobacco as in the instance of thrombo-angiitis obliterans. However, there is some evidence to indicate that smoking may produce a degree of vasoconstriction, a condition which presumably would have an unfavorable influence on the occurrence of such spasms.

DIPHTHERIA ANTITOXIN

To the Editor:—How late after the contraction of diphtheria is antitoxin effective?

R. L. CLINE, M.D., Lakeland, Fla.

ANSWER:—When diphtheria antitoxin is administered in sufficient dosage within the first two days of the disease, few patients fail to recover. The history of duration is often unreliable because of the insidious onset of diphtheria. Diphtheria antitoxin is efficient only in relation to its action on the free toxin; for the toxin that has combined with the body tissues, antitoxin is ineffective. Since there may be free toxin at any stage of acute diphtheria, antitoxin should always be given. The percentage of fatalities mounts rapidly with the increased number of elapsed days before antitoxin injection. Virulence of the infecting organism and degree of susceptibility of the patient are always important factors in any case of diphtheria. Patients have recovered who did not receive any antitoxin prior to the sixth or seventh day of the disease. It is wise to administer antitoxin in all active cases even if late in the disease.

NARCOLEPSY

To the Editor:—A youth, aged 18 years, 67 inches (170 cm.) tall, weighing 168 pounds (85 Kg.), has had narcolepsy since he was about 3 years of age. He is contemplating marriage in the near future and I should like advice as to whether or not it would be advisable to sterilize him.

R. C. FAUST, M.D., Eugene, Ore.

ANSWER.—Narcolepsy, or Gelineau's syndrome, as far as it is known, is not hereditary or familial. Therefore there is no reason to vasectomize a given individual with narcolepsy for purposes of sterilization. Cataplexy, which is another form of Gelineau's syndrome, must not be confused with familial periodic paralysis. The latter is familial. Assuming that the boy has a hypothalamic pituitary lesion resulting in adiposity, overweight and attacks of uncontrollable desire to sleep, it is suggested that he be placed on benzedrine sulfate in doses of 10 mg. two or three times daily. An anterior pituitary extract may be also given subcutaneously.

BLOOD IN ERYTHEMA MULTIFORME—LESIONS ON PENIS

To the Editor:—What blood picture has been observed in erythema multiforme? How often are lesions observed on the penile mucosa similar to those reported as occurring on the oral mucosa? I recently cared for a young white man with typical lesions of erythema multiforme following a mild attack of influenza. The cutaneous eruption was accompanied by a severe aphthous stomatitis (labial, gingival, buccal, palatal and pharyngeal mucosa) and by similar lesions of the glans penis. The history and Wassermann reaction were negative for syphilis and all lesions cleared in less than two weeks' time under local and general supportive treatment only.

M.D., Oklahoma.

ANSWER.—There is no distinct blood picture in erythema multiforme. Occasionally in the bullous type there may be some increase in the eosinophils.

Often in the bullous type and in the papular type there are lesions on the penile mucosa and on the vaginal mucosa, as well as on the mucous membranes of the mouth.

HYSTERECTOMY IN TABES

To the Editor:—A woman, aged 43, who states that she never had any primary or secondary lesions of syphilis and who was not treated until she developed tabetic symptoms, complains that she is unable to pass urine without pressing on the bladder. She also complains that her abdomen is getting bigger and that she has some abdominal discomfort. On examination there is a large fibroid uterus the size of a seven months pregnancy. What is the advisability of operation on tabetic patients?

M.D., Michigan.

ANSWER.—Assuming the general physical condition of the patient to be satisfactory, particularly from the cardiovascular standpoint, the fibroid uterus may be removed without regard to the tabes and with no reference to the state of the patient's serologic reactions in the blood and spinal fluid at the time of operation. Following operation it is of course advisable that she be under treatment for syphilis in order to guard against the remote possibility of difficulty with wound healing.

NO MEDICAL TREATMENT FOR CATARACT

To the Editor:—A man, aged 33, has a matured cataract in the right eye. An operation has been advised. Is there any other method recognized in treating the condition at this stage? He has been convinced by persons who were treated by a doctor in Philadelphia to try another procedure; that is, by some electrical apparatus. M.D., Pennsylvania.

ANSWER.—There is no medical or electrical treatment that will influence a mature cataract. Even though the patient is only 33 years of age it is advisable to submit to surgical treatment if for no other reason than the cosmetic purpose. Probably the worst ophthalmologic quackery of all time is the treatment of cataract by other than surgical means. The time may come when it can be done, but at present our knowledge is too limited.

MENTHOL IN URTICARIA

To the Editor:—What are the effects of administration of menthol in angioneurotic edema? For how long a period can it be given? Can it produce any toxic symptoms, and what are these symptoms?

M.D., New York.

ANSWER.—Menthol is used externally only as a mild antipruritic in angioneurotic edema. While it also acts as an antipruritic when given internally, its effect as such is so uncertain and slight that there is no reason for employing it as a substitute for such drugs as epinephrine and ephedrine. The primary objection to its use by mouth is the irritating effect on the gastric mucosa. Toxic symptoms may occur in

rare cases when given by mouth. Champeau reports grave but not fatal symptoms of cardiovascular collapse in a child, aged 4½ years, from ingestion of 6 mg. of menthol (*Bull. Acad. de méd.* 114:448 [Nov. 19] 1935). Parenterally, toxic symptoms may be produced. The symptoms are those of paralysis of the central nervous system, especially the medulla.

LATE RESULTS OF RADIUM APPLICATIONS TO CERVIX

To the Editor:—What is the longest known delayed radium reaction from applications to the cervix?

M.D., South Carolina.

ANSWER.—Vesicovaginal fistulas ascribable to radium applications usually occur within three months, not infrequently as late as six months after radium treatment, rarely after an interval of a year. Deep sclerosing lesions of the pelvis, simulating a malignant condition and really ascribable to radium reaction, may be followed by necrosis of the tissues even several years subsequent to the use of radium.

It is of the utmost importance that emphasis be placed on the factor of distance from the irradiated tissues in the susceptibility to burns and fistulas. The quantity of radium used is a lesser factor in contrast with the nearness of the application and the amount of screening employed.

SALICYLATES IN PULMONARY TUBERCULOSIS

To the Editor:—Should salicylates, especially acetylsalicylic acid, be used by patients suffering from active pulmonary tuberculosis, who, because of their tendency to raising blood, are properly known in the sanatorium as "streakers"? It has been my experience that a large percentage of such patients "streak" more easily if acetylsalicylic acid is used, so much so that I avoid its use. A former member of this staff had a similar experience. VIRGIL F. NEUMANN, M.D., Norwich, Conn.

ANSWER.—There is much justification for the suspicion that salicylates and acetylsalicylic acid cause increased blood flow in patients who "streak" blood. They have a slight tendency to increased blood flow, although the cause is not known; presumably it is due to a slight lowering of viscosity or to a change in coagulability. The degree is not great, however, and the risk is practically nil, even in serious cases. In only a few cases out of many thousands, in the experience of a large institution, has it been necessary to avoid such treatment, and then a shift to aminopyrine and caffeine has met the requirements with no ill effects.

ACHOLIC STOOLS FROM HEPATITIS

To the Editor:—Is it possible to get obstructive jaundice, with complete absence of bile in the stools, due entirely to a hepatitis, with no obstruction in the bile duct outside the liver? The question has come up in a young person who has been receiving antisyphilitic treatment.

M.D., North Carolina.

ANSWER.—It is entirely possible, in cases of severe hepatitis of the toxic type, particularly that associated with antisyphilitic treatment, for a patient to get acholic stools without any obstructive manifestations in the larger bile ducts. This case resembles that of a severe arsphenamine type of jaundice.

SALT AND CALCIUM IN TROPICS

To the Editor:—My daughter in Brazil has been urged by me to take salt in that tropical heat, whereas her dentist tells her not to because of her lack of calcium in nursing a big baby of 6 months. To what extent would the calcium need affect the need for salt in excessive perspiration? They are on the equator at sea level.

M.D., Michigan.

ANSWER.—The fact that the patient is nursing a baby is no contraindication to taking salt for excessive perspiration. If the patient has a negative calcium balance, as is apparently suspected by her dentist, this should be corrected by the usual method of fortifying the diet with adequate available calcium. The patient should receive both the salt and the calcium.

SMALLPOX VIRUS FOR HERPES SIMPLEX

To the Editor:—In *Queries and Minor Notes* in the April 30 issue of THE JOURNAL is a question regarding the prevention of herpes simplex. I should like to add a supplementary remark with the hope that it will provoke further discussion. Smallpox virus has been advised for the immunization of patients to herpes simplex. It is done once a week for eight weeks in exactly the same way as vaccination against smallpox. It seems to be effective. It would seem important to reconcile the effect of smallpox virus with the effect of the virus isolated from herpes simplex.

HAROLD J. HARRIS, M.D., Westport, N. Y.

Medical Examinations and Licensure

COMING EXAMINATIONS

STATE AND TERRITORIAL BOARDS

Examinations of state and territorial boards were published in THE JOURNAL, June 11, page 2028.

NATIONAL BOARD OF MEDICAL EXAMINERS

NATIONAL BOARD OF MEDICAL EXAMINERS: *Parts I and II.* Examinations will be held in all centers where there is a Class A medical school and five or more candidates who wish to write the examination, June 20-22 and Sept. 12-14. Ex. Sec., Mr. Everett S. Elwood, 225 S. 15th St., Philadelphia.

SPECIAL BOARDS

AMERICAN BOARD OF INTERNAL MEDICINE: *Written examination* will be held at various centers of the United States and Canada, Oct. 17. *Final date for filing applications is Sept. 1.* Chairman, Dr. Walter L. Biering, 406 Sixth Ave., Suite 1210, Des Moines, Iowa.

AMERICAN BOARD OF OPHTHALMOLOGY: Washington, D. C., Oct. 8, and Oklahoma City, Nov. 15. *All applications should be filed immediately and case reports, in duplicate, must be filed not later than sixty days before the date of examination.* Sec., Dr. John Green, 3720 Washington Blvd., St. Louis, Mo.

AMERICAN BOARD OF PEDIATRICS: Detroit, October 26; Rochester, N. Y., November 13; and Oklahoma City, November 15. Sec., Dr. C. A. Aldrich, 723 Elm St., Winnetka, Ill.

Maine March Report

Dr. Adam P. Leighton, secretary, Maine Board of Registration of Medicine, reports the written examination held at Portland, March 8-9, 1938. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Seventeen candidates were examined, 15 of whom passed and two failed. One physician was licensed by reciprocity and one physician was licensed by endorsement after an oral examination. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
George Washington University School of Medicine.....	(1937)		83.5
Georgetown University School of Medicine.....	(1937)		87.9
University of Maryland School of Medicine and College of Physicians and Surgeons.....	(1937)		84.6
Boston University School of Medicine.....	(1933)	83.6	84.8
Harvard University Medical School.....	(1935)	85.9	84.7
Tufts College Medical School.....	(1937)	76.5	82.7
University of Rochester.....			83.8
Jefferson Medical College.....			82.2
School of Medicine and.....			75.6
University of Montreal.....			76.8
Université de Paris Fac.....			75.9

School	FAILED	Year Grad.	Per Cent
Friedrich-Wilhelms-Universität Medizinische Fakultät, Berlin.....	(1929)		68.1
National University of Athens School of Medicine.....	(1935)		55.6

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
Long Island College Hospital.....	(1893)		Vermont

School	LICENSED BY ENDORSEMENT	Year Grad.	Endorsement of
Harvard University Medical School.....	(1935)		N. B. M. Ex.

Arizona April Report

Dr. J. H. Patterson, secretary, Arizona State Board of Medical Examiners, reports the written examination held at Phoenix, April 5-6, 1938. The examination covered 10 subjects and included 100 questions. An average of 75 per cent was required to pass. Two candidates were examined, both of whom passed. Six physicians were licensed by reciprocity and two physicians were licensed by endorsement. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
University of Illinois College of Medicine.....	(1937)		75.8*
University of Vermont College of Medicine.....	(1936)		81.3

School	LICENSED BY RECIPROCITY	Year Grad.	Reciprocity with
School of Med. of the Division of Biological Sciences.....	(1931)		Illinois
Tulane University of Louisiana School of Medicine.....	(1932)		Louisiana
Washington University School of Medicine.....	(1934)		Missouri
Albany Medical College.....	(1930)		New York
Cleveland College of Physicians and Surgeons.....	(1912)		Ohio
Western Reserve University School of Medicine.....	(1925)		Ohio

Rhode Island April Examination

Mr. Robert D. Wholey, chief, Division of Examiners, reports the oral, written and practical examination held by the Board of Examiners in Medicine at Providence, April 7-8, 1938. The examination covered 20 subjects and included 50 questions. An average of 80 per cent was required to pass. Five candidates were examined, all of whom passed. Five physicians were licensed by endorsement after an oral examination. The following schools were represented:

School	PASSED	Year Grad.	Per Cent
Tufts College Medical School.....	(1936)		87.5
Cornell University Medical College.....	(1935)		87
Jefferson Medical College of Philadelphia.....	(1935)		83.5

Book Notices

Heart Disease in General Practice. By Paul D. White, A.B., M.D., Assistant Professor of Medicine, Harvard University Medical School, Boston. National Medical Monographs. Edited by Morris Fishbein, M.D. Cloth. Price, \$3. Pp. 338, with 47 illustrations. New York: National Medical Book Co., Inc., 1937.

Dr. White, the author of this book, is one of the leading cardiologists of the United States. In the preface he states that the book is an "attempt to serve the family physician by compiling a brief but practical and forceful summary of our present knowledge of the diagnosis, prognosis and treatment of heart disease." He employs the question and answer method and has included many of the questions of the general practitioner. The book is divided into four parts: the historical introduction (7 per cent), the field of diagnosis including symptomatology, signs, blood pressure, electrocardiography and x-ray examination (48 per cent), prognosis (4 per cent) and treatment (34 per cent); the remainder consists of preface and index. Selecting at random pregnancy and heart disease as one of the common problems of the general practitioner, one finds this subject considered with a single question and a two page answer. The discussion does not include prevention or treatment of congestive failure. Taking the management of acute coronary thrombosis as another question, there is an excellent summarization of the modern concept of diagnosis and the treatment of this common problem. Another question is that of treatment of cardiovascular syphilis, in which Dr. White advocates potassium iodide, mercury or bismuth compounds and nearsphenamine up to 0.4 Gm., which might lead a practitioner into serious complications. On the whole the book is well arranged and the discussions of the various topics represent current views in modern cardiovascular practice. One might be critical of the attempt to summarize such a broad subject in such a small book. The volume will prove interesting reading to a number of practitioners, and they hold the ultimate answer as to whether or not Dr. White has achieved his purpose.

The British Encyclopaedia of Medical Practice Including Medicine, Surgery, Obstetrics, Gynaecology and Other Special Subjects. Under the General Editorship of Sir Humphry Rolleston, Bt., G.C.V.O., M.D. Volume VI: Gonorrhoea to Hydrotherapy. Cloth. Price, \$12. Pp. 602, with 96 illustrations. London & Toronto: Butterworth & Co. (Publishers), Ltd., 1937.

From "gonorrhoea" to "hydrotherapy" is the field covered by the sixth volume of this encyclopedia, the leading titles including some fifteen pages on gout, seventy-five pages on topics beginning with "hema," twenty-seven pages on the hand and 150 pages on the heart. Other important headings concern heat, heredity and hernia. The authors of note in this volume are Colonel Harrison, who writes on gonorrhea on the basis of a large experience during the Great War and since, and many leading British physicians whose names are associated with diseases of the blood. Whitfield discusses the hair and Reginald Miller in a succinct statement gives the important facts regarding rheumatic heart disease in children. The name of C. P. Symonds is associated with articles on headache and on hydrocephalus. The volume is fully up to the standard of the previous volumes in typography, illustration and the quality of the material.

The Income Structure of the United States. By Maurice Leven. Assisted by Kathryn Robertson Wright. Cloth. Price, \$1.50. Pp. 177. Washington, D. C.: Brookings Institution, 1938.

The more the income problem is studied the more complex it becomes. It is not always the same as money received or expended. There are still important survivals of "barter economy." There are wide variations as to industries and as to occupations within industries. Business incomes are modified by lobbying, legislation, trade associations and business combinations. Farmers' incomes are affected by legislation and cooperative organizations as well as by location. The influence of unions on labor incomes is steadily growing. The cyclic fluctuations change total income and also its distribution among individuals and groups. Seasonal conditions, strikes, technological developments and the existence of largely immobile and

stranded populations greatly affect the picture. Hourly wages appear to have increased somewhat since 1929, but as the length of the working week has declined "total annual wages in 1936 were, however, below the preponderance level." There are, however, numerous exceptions to this statement. Of eighty-nine industries, thirty-one had higher weekly earnings in June 1937 than in 1929. If increase in productivity is sufficiently raised, living standards may not suffer from shortened hours. The decline in incomes since 1929 has hit professional workers somewhat harder than the rest of the population. "The professional incomes of physicians in the 1936 array were between 18 and 30 per cent lower than in the 1929 array; lawyers' incomes were between 18 and 38 per cent lower in the array for 1936 than in that for 1929." Wages and salaries have shown wider fluctuations and somewhat more of a recovery from the depression low than "entrepreneurial withdrawals." Dividends and interest were least affected by the cyclic change. While "most of the employed industrial wage earners seem to have forged ahead of their predepression position by the middle of 1937, this gratifying condition, however, was marred by the fact that in 1937, even before the recession in the latter part of the year, there were still some 8 to 9 million people unemployed in the United States." The latter number is close to the additional wage earners created by the increase in population during these years.

Annual Reprint of the Reports of the Council on Pharmacy and Chemistry of the American Medical Association for 1937 with the Comments That Have Appeared in The Journal. Cloth. Price, \$1. Pp. 201. Chicago: American Medical Association, 1938.

This issue of the collected reports includes the reports on Avertin with Amylene Hydrate (now accepted for New and Nonofficial Remedies), Benzedrine Sulfate (the active constituent of the notorious "pep" pills but a promising drug when its limitations are recognized), Catgut Sutures (a survey of the sterility of the market supply), Evipal Soluble (a comprehensive review of the evidence for the usefulness and limitations of the drug), Histidine Hydrochloride (a study of the usefulness of the drug in peptic ulcer, to be considered in connection with the report rejecting Larostidin, a proprietary brand, for unwarranted and exaggerated claims), Mandelic Acid (an authoritative statement of the limitations of this drug which the Council has now accepted), and Vinethene (a careful study of the evidence for the drug, which the Council has accepted for one year as an anesthetic to be used in short procedures).

Two reports of interest to those who have been following the Council's considerations are those finally rejecting Edwilen and Gonococcus Filtrate (Corbus-Ferry). The Edwilen report represents a thoroughgoing demolition of the exaggerated claims that have been made for this pseudoscientific preparation. The report on Gonococcus Filtrate is the third of a series of reports illustrating the patient carefulness with which the Council considers the evidence for a preparation and the progressing failure of the evidence for Gonococcus Filtrate to substantiate the promise which it at first appeared to show. Another illustration of the Council's recurrent consideration of a product is the report on Pantopon "Roche." Since the omission of this product from New and Nonofficial Remedies in 1931, the Council has at various times been forced to consider promotional material issued by the manufacturer repeating and emphasizing the extravagant and unwarranted claims because of which it had been omitted.

Other reports of outright rejection of products are those on Causalin (Causyth), an unsafe and dangerous preparation proposed for use in arthritis; Glutamic Acid Hydrochloride-Calco, proposed as a conveyor of hydrochloric acid, with unsubstantiated claims of clinical effectiveness, and Larodon "Roche," proposed as a substitute for other well established analgesic and antipyretic drugs and marketed with exaggerated and unwarranted claims.

The Council's constant and increasing interest in vitamin therapy is shown in the following reports: ConDol and Ertren Not Acceptable for N. N. R., a rejection of two high potency vitamin D preparations proposed for use in the treatment of arthritis; Dosage of Preparations Containing Vitamins A and D, an attempt to bring some uniformity into the dosage statements for the various accepted vitamins A and D preparations;

The Use of Hydroquinone as a "Stabilizing" Agent in Preparations Containing Vitamin A, a rejection of such use; Riboflavin, the accepted name for Vitamin B₂; and Thiamin Chloride, the Council's new name for the hydrochloride of Vitamin B₁, and Viosterol (A. R. P. I. Process) in Oil.

The report on omission of Pentobarbital Sodium-Abbott should be mentioned in connection with the Council's interest in nomenclature of drugs. Since 1931 the Council has accepted two brands of pentobarbital sodium. Claiming priority for its product, the Abbott Laboratories has for some time insisted on the use of the proprietary name "Nembutal" for pentobarbital sodium. Perusal of the lengthy report indicates the Council's attitude on the use of proprietary names. It should be read by all who may be disposed to regard such matters as of relative importance. Further exposition of the Council's attitude on nomenclature is found in the report on the controversy with Sir Henry Dale over the name Ergonovine.

Two reports on Sulfanilamide appear, a nomenclature and status report together with reprints of THE JOURNAL editorials giving the warnings which, if obeyed, would have avoided the series of deaths which resulted from the marketing of the ill fated Elixir of Sulfanilamide-Massengill.

At the end of this volume appears a eulogy of George Henry Simmons, whose death deprived the Council on Pharmacy and Chemistry of its founder and American medicine of a worthy and faithful servant.

The Time Has Come . . . By Sir Arthur Hurst, M.A., D.M., Senior Physician to Guy's Hospital. The Harveian Oration Delivered Before the Royal College of Physicians of London on St. Luke's Day, 1937. Cloth. Price, 5s. Pp. 42. London: Headley Brothers [n. d.].

This is the two hundred and eighteenth Harveian oration delivered before the Royal College of Physicians in London. The first of the lectures to be delivered in English was given in 1865, although Harvey left the injunction that the oration should be in Latin. While the name of Harvey is closely associated with his studies of the circulation, he also made fundamental observations on the stomach and the digestion. Sir Arthur Hurst reviews contributions to the advancement of this phase of medical science and in the introduction and in the conclusion of his oration refers to the nature and purpose of the establishment of the Harveian oration. Since the time of Sir Henry Hallford, who was president of the Royal College of Physicians between 1820 and 1844, only one physician, Lord Dawson, has occupied that chair for seven consecutive years.

Baron Constantin von Economo: His Life and Work. By his Wife and by Prof. J. von Wagner-Jauregg. Translated from the second German edition by Ramsay Spillman, M.D. Cloth. Price, \$2. Pp. 126, with illustrations. New York: Ramsay Spillman, 115 East 61st Street, 1937.

Von Economo's researches were fundamental and opened a new pathway to the study of human behavior. His biography is written by his wife, who disavows any pretense to literary style yet by that very factor gives truth and personality to her writings. Few people know that von Economo was an enthusiast in aeronautics, including the balloon and the airplane, holding high office in organizations devoted to such work and sport. During the World War he served with the Austrian army on the Russian front and later in the Tyrol in 1916. Following the death of his brother in the service he returned to Austria to join the Wagner-Jauregg clinic. Von Economo was a learned man who read widely in the classics and was familiar also with art and music. His drawings of portions of the brain and of the special senses are described as "little works of art." He proposed that the brains of great men be saved for scientific study. During his career he twice visited the United States, the last visit, in 1929, including the eastern seaboard from Boston to Miami. He died in October 1931 from a severe angina. The brief record of his life is followed by an appreciation of his scientific work by Wagner-Jauregg and a reprinting of some of his most significant contributions. The name of von Economo is particularly associated with the identity of the condition now called epidemic encephalitis or lethargic encephalitis. Toward the end of his career von Economo was instrumental in establishing in Vienna an institute for brain research. Then he died and his right-hand man, Dr. Horn, survived him but a short time. With them the institute for brain research disappeared. Considering the recent changes that have taken

place in medicine in Vienna, it is perhaps just as well that these scientists should have completed their own contributions and passed on before the inevitable heartbreak that would have come to them in recent years.

Traumatismes du pied et rayons X: Malléoles, astragale, calcanéum, avant-pied. Par Etienne Destot. Préface du Dr Alexis Carrel. Second edition. Paper. Price, 45 francs. Pp. 292, with 156 illustrations. Paris: Masson & Cie, 1937.

Even though this book is by an eminent surgeon of France, carrying a foreword by Alexis Carrel, it is merely a catalogue, with innumerable roentgenographic illustrations, of fractures at the ankle and tarsus. There is little on treatment and practically no method of reduction or immobilization is described or illustrated. Destot was one of the first French surgeons to appreciate the value and the limitations of the roentgen ray in surgery of fractures. From the extensive array of roentgenograms of old improperly healed or reduced fractures of the ankle and tarsus one would be inclined to believe that the x-ray method had been neglected for both immediate diagnosis and position determination of fragments and also for the x-ray record of the proper reduction. There is absolutely no mention of the Boehler salient for the linear determination of reduction of the fracture of the os calcis, and this does seem to offer definite help. Destot died in 1918 following arduous surgical service and roentgen exposure during the war period. This edition has been revised by two admiring pupils and associates. It is a voluminous French essay on fractures of a limited but important part of the body but it does not begin to be a complete treatise of any great practical value to the American industrial or railroad surgeon or general practitioner. The book shows how Destot can adorn the tarsus with beautiful word-flowers, only to have them wilt under the scorn of this practical analysis of their true values.

Pathology. By E. B. Krumbhaar, M.D., Professor of Pathology University of Pennsylvania School of Medicine, Philadelphia. XIX, *Clio Medica: A Series of Primers on the History of Medicine*. Edited by E. B. Krumbhaar, M.D. Cloth. Price, \$2. Pp. 206, with 18 illustrations. New York: Paul B. Hoeber, Inc., 1937.

The little volumes published as a medical historical collection under the title "Clio Medica," begun by the late Paul B. Hoeber, now occupy a sizable area on the book self. Since pathology is basic in the development of every branch of medical science, Krumbhaar's contribution is one of the most significant in the series. He has divided his work into a series of chapters dealing with early concepts, the rise of the anatomic concept in disease, precellular and cellular pathology, and finally integrated pathology. Quite as valuable as the text itself are the series of appendixes dealing with the word "pathology," early chairs for the teaching of the subject, and a chronological list of milestones. There is also a bibliography and a good index. The very concentration of the work inclines to make it well nigh a list of names, dates and accomplishments, yet the author has been able, here and there, to introduce something of literary flavor.

Medico-Legal Aspects of the Ruxton Case. By John Glalster, M.D., D.Sc., Barrister-at-Law, Regius Professor of Forensic Medicine, University of Glasgow, and James Couper Brash, M.A., M.D., F.R.C.S., Professor of Anatomy, University of Edinburgh. Cloth. Price, \$6. Pp. 284, with 172 illustrations. Baltimore: William Wood & Company, 1937.

This is not the kind of book that can be recommended to readers of detective stories. It is a scientific work describing the medicolegal aspects associated with two murders in which the victims were terrifically mutilated. The victims were the wife of a physician and the nursemaid from the physician's home. The doctor was charged with the murders, tried and convicted. From this conviction he appealed and the appeal was dismissed. As it was necessary to reconstruct the bodies from the remains, to determine their sex and to identify them, to analyze the feet and the fingerprints and to make anthropologic studies of the skulls and to reconstruct the face from these portions, the book offers opportunity for a vast amount of instruction on identification. There was also the question of blood stains found on clothing and on the household furnishings and identification of this material. The book is illustrated and should be of special interest to all who carry on medicolegal work.

The Treatment of Clinical and Laboratory Data: An Introduction to Statistical Ideas and Methods for Medical and Dental Workers. By Donald Mainland, M.B., Ch.B., D.Sc., Professor of Anatomy, Dalhousie University Halifax, Nova Scotia, Canada. Cloth. Price, 15s. Pp. 340, with 23 illustrations. Edinburgh & London: Oliver & Boyd, 1938.

This is a welcome addition to the books now available on the statistical method in biologic and medical research. Because of its emphasis on biologic and medical problems and the deletion of all but the most necessary mathematical formulas, it is exceptionally readable. Many important aspects of the statistical method are brought out and illustrated with actual examples. The explanation of the use of the chi square test, for instance, is brief and lucid. In fact, any one with a high school education and a small amount of concentration could readily understand its applicability. For those desiring to go somewhat more deeply into the subject, there is a chapter of supplementary notes which, while more complicated, is nevertheless simply and clearly presented. There would now seem to be no excuse for the presentation of statistically oriented medical papers without some conception of the statistical elements involved and the pitfalls most commonly encountered.

Materia Medica, Pharmacology, Therapeutics and Prescription Writing for Students and Practitioners. By Walter Arthur Bastedo, Ph.M., M.D., Sc.D., Consulting Physician, St. Luke's Hospital, New York. Fourth edition. Cloth. Price, \$6.50. Pp. 778, with 81 illustrations. Philadelphia & London: W. B. Saunders Company, 1937.

This edition has been revised and many new parts have been added. The textbook is designed particularly for students and practitioners; the author states in the preface that it is for the practicing physician rather than for the scientist. It differs from other standard textbooks of this type in that it consists essentially of the author's lectures and, while it is interesting reading, it is less suitable for detailed reference work since it does not contain (any more than a lecture would contain) the bibliography on which the material is based. The author makes full acknowledgment of many source books. All the newer drugs are discussed in full detail and the evaluation of the current references to the literature is a reflection of the author's ability in this field. Examples of such critical review are the discussions of the marihuana habit, cyclopropane, mandelic acid and sulfanilamide. The volume includes discussion of prescription writing and posology. This edition should have the success of its predecessors.

Sbornik posvyashchenny 35-letiyu vrachebnoy, nauchnoy, prepodavatel'skoy i obshchestvennoy deyatelnosti zasluzhennogo deyatelya nauk Professora Aleksey Ivanovicha Abrikosova. Pod redaktsiy Prof. P. D. Solovova. [Collection Celebrating 35 Years of Professional, Scientific and Communal Activity of Professor Aleksey Ivanovich Abrikosov.] Cloth. Price, 11 rubles, 50 kopecks. Pp. 364, with illustrations. Moscow & Leningrad: Gosudarstvennoe izdatel'stvo biologicheskoy i meditsinskoy literatury, 1936.

This is a collection of papers by the staff of the Botkin Hospital, Moscow, presented to the pathologist A. I. Abrikosov on the occasion of the completion of thirty-five years of his scientific and pedagogic activities. The major part of the papers is devoted to anatomic and pathologic subjects. They reflect a fairly high level of accomplishments in the field in which Abrikosov, their teacher and co-worker, is a prominent figure.

The Public Assistance Worker: His Responsibility to the Applicant, the Community, and Himself. Edited by Russell H. Kurtz. Cloth. Price, \$1. Pp. 224. New York: Russell Sage Foundation, 1938.

The extraordinary expansion and transformation of nearly all phases of public assistance during recent years have called for new attitudes and ability to meet new tasks on the part of those concerned with public assistance. Permanent state public welfare agencies have succeeded state emergency relief administrations and are seeking to coordinate all types of public assistance. Each chapter is by a different author, yet the book as a whole is consistent and well organized. The old attitudes toward standards of need, residence requirements and other traditional qualifications for relief which characterized the old Poor Law are disappearing. Cash relief, with the individual right to choose how it will be expended, is approved. The problems of health and medical care are considered, with thorough recognition of the necessity of individualizing the problem and giving the patient the right to choose his own physician. While it is stated that "there is a strong case to be made for

health insurance," the objections to it on the ground that it "lowers the quality of medical care, the quality of the medical man, and the quality of the patient's conception of health" and also that "no compulsory insurance scheme would provide medical care to all persons who need services at low cost" are recognized. Emphasis is rightly laid on the problems of housing, nutrition and income in relation to disease and the place of public health departments in caring for community conditions.

Diseases of the Blood. By Cyrus C. Sturgis, M.D., B.S., Professor of Medicine, University of Michigan Medical School, Ann Arbor, Michigan, and Raphael Isaacs, A.B., A.M., M.D., Associate Professor of Medicine, University of Michigan Medical School, Ann Arbor, Michigan. National Medical Monographs. Edited by Morris Fishbein, M.D. Cloth. Price, \$3. Pp. 302, with one illustration. New York: National Medical Book Co., Inc., 1937.

During the last few years there has been a remarkable growth of interest in the diseases of the blood. Several large monographs, beautifully illustrated with color plates, have appeared within a short time. While these large books have been welcomed by hematologists, clinical pathologists and internists, there has been a decided need for a small, reasonably priced, lucid and authoritative book particularly planned for the general practitioner. This monograph admirably fulfills these requirements. The broad experience of the authors in the clinical management of diseases of the blood, as well as their well known contributions to hematologic research, provided them with a wealth of material from which to select the subject matter. Details of technic and illustrations of the various blood cell types have been omitted. The relative length of the subject matter in the various chapters parallels the clinical importance of the various diseases. Thus the chapter on pernicious anemia occupies fifty-seven pages, while that on sickle cell anemia occupies but nine pages. Proper emphasis is given to the treatment of the various diseases of the blood and the blood-forming organs. The book is written in a clear, concise, eminently readable style and is printed in large, legible type. It richly deserves the favorable reception it is certain to receive from the general practitioner.

Treatment in General Practice. By Harry Beckman, M.D., Professor of Pharmacology at Marquette University School of Medicine, Milwaukee, Wis. Third edition. Cloth. Price, \$10. Pp. 787. Philadelphia & London: W. B. Saunders Company, 1938.

The third edition of this work is no larger than the previous two editions, because experience has enabled the author to eliminate some material and to condense some portions of the book. There has been reorganization of the material by including diabetes with the endocrine diseases and giving obesity and malnutrition a separate section. The new section which has been added deals with nutritional disturbances, diseases of the liver and bile passages, disturbances of water, salt and protein balance, those caused by heat, and the anemias. A number of conditions are now considered for the first time, notably alkalosis, Ménière's disease, physical allergy, prophylaxis of the venereal diseases, colon consciousness, and some ear, nose and throat disturbances. Obstetric conditions, drug addiction and some tropical conditions have been eliminated from consideration. The work continues to be one of the most practical that are available in the field of therapy, is easily understood, and for the most part is abreast of the times. However, some new promising forms of therapy which are not perhaps as yet well established have not been included, notably in the treatment of psoriasis and in pneumonia.

English-German and German-English Medical Dictionary. By Joseph R. Waller, M.D., and Moritz Kaatz, M.D. Teil 2: Deutsch-Englisch Englisch-Deutsch und Deutsch-Englisches medizinisches Wörterbuch. Seventh edition by Dr. Franz von Braltenberg. Cloth. Price, 7 marks. Pp. 238. Leipzig & Vienna: Franz Deuticke, 1935.

The seventh edition of this useful little dictionary is to all intents and purposes simply a new printing of the sixth edition. It contains no new material, and the old definitions are unchanged. The noteworthy feature of the book is, as before, the limitation of its vocabulary to strictly medical terms. It includes a surprisingly large number of words within its small confines. The medical student, general practitioner or layman unfamiliar with medical terminology will find it very helpful.

The Diary of a Surgeon in the Year 1751-1752. By John Knyveton, Licentiate of the Society of Apothecaries; Doctor of Medicine of the University of Aberdeen; Teacher of Midwifery to and Man Mid-Wife in Infirmary Hall; Surgeon's Mate, H. M. S. Lancaster. Edited and transcribed by Ernest Gray. Cloth. Price, \$2.50. Pp. 322, with 9 illustrations. New York & London: D. Appleton-Century Company, Incorporated, 1937.

The lives of physicians are romantic. They are particularly romantic in the period covered by this diary. The diary is pieced together much as one might piece together a piece of fiction based on the diaries of Evelyn, Pepys and Walpole. This book is apparently based on the autobiography of Thomas Denman, to which are added statements by his son-in-law Matthew Baillie as they appeared in his seventh edition of "Practice of Midwifery." Names and dates are changed in some instances. This leads to errors, such as when the diarist speaking of the treatment of scurvy, presumably in 1751, refers to James Lind's "On the Diseases of Europeans in Hot Climates," which did not appear until 1768. The book presents an interesting picture, and the diary method gives it a tone of veracity which adds to its flavor.

Sbornik posvyashchenny 35-letney vrachebnoy, nauchnoy i obschestvennoy deyatelnosti professory Vladimira Nikolaevicha Rozanova. Redaktor: Prof. P. D. Solovov. [Collection Celebrating 35 Years of Professional, Scientific and Communal Activity of Professor Vladimir Nikolaevich Rozanov.] Cloth. Pp. 359, with illustrations. Moscow & Leningrad: Gosudarstvennoe meditsinskoe izdatelstvo, 1934.

This is a collection of papers presented by the staff of the Botkin Hospital, Moscow, to V. N. Rozanov, chief of the surgical division of the hospital, on the occasion of completion of thirty-five years of his clinical, pedagogic and investigative activities. Most of the papers deal with surgical subjects. The quality of the surgical work reflected in these contributions is a compliment to Rozanov, who has contributed much to the development of the surgical service at the Botkin Hospital.

Practical Bacteriology, Haematology and Animal Parasitology. By E. R. Stitt, M.D., Sc.D., LL.D., Paul W. Clough, M.D., Chief of Diagnostic Clinic, Johns Hopkins Hospital, Baltimore, and Mildred C. Clough, M.D. Ninth edition. Cloth. Price, \$7. Pp. 961, with 208 illustrations. Philadelphia: P. Blakiston's Son & Company, Inc., 1938.

The standards of the ninth edition of this reference book have been well maintained. As in the past, special emphasis has been laid on the interpretation and diagnostic significance of laboratory procedures. Advance in this field has necessitated considerable revision and addition especially with regard to filtrable viruses and hematology. An entirely new chapter on the fungi has been prepared, and it was necessary largely to rewrite the chapter on immunity and hypersensitiveness. The concise and careful descriptions in this book keep it a practically necessary fixture in the laboratories of all those physicians carrying out any but the simplest technics.

The Tercentenary of Harvard College: A Chronicle of the Tercentenary Year 1935-1936. Cloth. Price, \$4. Pp. 492, with 37 illustrations. Cambridge, Massachusetts: Harvard University Press, 1937.

This volume includes the story of the tercentenary, beginning with organization and preparation, and a description of the university, of the special settings provided, a chronicle of the tercentenary year, and a complete report of each of the days. Included also are the addresses made by various speakers, the congratulatory messages and a complete list of all those who collaborated on the various occasions. The volume is handsomely published by the Harvard University Press and is a fitting memorial of a great occasion.

Blodinamika proteidiv. Pld redaktsleyu akademika O. O. Bogomoltsya. [Blodynamics of Proteins.] Paper. Price, 5 krb. 50 kopecks. Pp. 241. Klier: Vidavnistvo Akademii Nauk URSR, 1938.

The discussion of the nature of proteins presented in this volume is abreast of the times and is quite exhaustive. The volume emanates from the Institute of Clinical Physiology, a branch of the Ukrainian Academy of Sciences. Since it is written in the Ukrainian it will be not accessible even to those workers—physiologic chemists—who would naturally be most interested in it. Such valuable contributions should, in the interest of interchange of ideas, be rendered into one of the more accessible languages.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Pneumonia Attributed to Lowered Resistance Resulting from Industrial Accident.—A workman, in the course of his employment, August 22, ran a sliver into his finger. Infection followed and on September 5 he sought treatment at a first aid hospital maintained by his employer. There he was treated for eight days and then discharged. He lost no time from work. The following April, about eight months after the accident, he contracted pneumonia and died. His widow was awarded compensation under the Michigan workman's compensation act, on the theory that the infection from his finger injury "caused his system to run down, with a lowering of resistance, so as to make him susceptible to pneumonia." The employer appealed to the Supreme Court of Michigan.

At the hearing before the department of labor on the widow's claim for compensation, the widow testified that the deceased, after he had been discharged from the employer's first aid station, continued to suffer pain in his injured finger; that he would wake up in the middle of the night and bathe his finger in epsom salts and hot water; that after the injury he lost weight and became irritable, and that progressively his system ran down so that he caught the cold which resulted in the fatal pneumonia. It was testified, too, that the decedent perspired heavily from his work and that he stood in a place where he might easily have caught cold from a draft. There was other slight evidence that the deceased had lost weight following his injury and thereafter worked with a bandage over his gloves. Medical testimony in response to a properly framed hypothetical question attributed the pneumonia to decedent's lowered resistance caused by the infection in the finger.

It is well settled, said the Supreme Court, that if a person, as the result of an industrial accident, becomes so run down and his resistance is so lowered that the injury contributes to pneumonia, and this is borne out by medical experts, recovery may be had under the Michigan workmen's compensation act. The Supreme Court of Michigan has no right to pass on the weight of the testimony, even though it might readily reach a different conclusion than that of the trial tribunal. There being some testimony to support the widow's claim, this court must affirm the award.

The award in favor of the widow was accordingly affirmed, although modified in some respects not material to this abstract. —*Seifman v. Ford Motor Co. (Mich.)*, 276 N. W. 472.

Workmen's Compensation Acts: Diabetic Gangrene Attributed to Trauma.—Sutliff had been suffering from diabetes mellitus for about two years, gradually losing weight but continuing to work. In the course of his employment he "bumped" his right leg. He finished his day's work, but when he arrived home he was pale and limped. That evening his wife noticed a small red spot on the inside of his right leg at or about the knee. She then applied a bandage, saturated with alcohol, to his right knee to relieve the pain. He worked the next day until noon, when his leg became so painful that he was forced to quit work. A physician, called the following day, found a small red spot on the outside of his knee but noticed no abrasion or break of the skin. Hot dressings and an electric pad were applied in accordance with the physician's orders but the injured workman grew worse. A few days later a blister appeared three or four inches below the knee, which "showed signs of wet gangrene." Death occurred about one month after the accident. The attending physician certified that "The Primary Underlying Cause of death was Diabetes Mellitus Duration 2 yrs."; that a contributory cause was "diabetic Gangrene Duration 1 mo."; and that the disease or injury was in no way related to the occupation of the deceased. The

industrial commission denied compensation to the widow and she appealed to the Supreme Court of Minnesota.

In determining the origin of the gangrene, apparently no importance was attached to the application of the bandage saturated with alcohol or of the hot dressings and electric pad. Two medical experts testified on behalf of the widow, one of them the attending physician, and their testimony, said the court, may have "made a prima facie case." A physician who appeared as a witness on behalf of the employer testified, however, that there was no causal relation between the accident and the workman's death; in his judgment, if the accident had played a part in the development of the gangrene, the effect of the trauma would have appeared where the injury occurred, if there was "a break in the skin in that area." The fact that the blister appeared elsewhere meant, according to this witness, that the accident had nothing to do with it; there must have been a break in the skin from some other cause. If there was a break in the skin at the toes, the trouble would work upward through the lymphatics, but such conditions do not work downward in that way. Such a disorder as that from which the deceased died does not develop without some point of entry. The record does not show whether the testimony of this witness referred to the development of moist gangrene or of infection or of both.

The causal relation, said the Supreme Court, between the accident and the resulting condition of Sutfief was obviously a question of fact for the triers of fact, the industrial commission. This court, as a court of review, cannot try such issues. Its only authority was to determine "whether there is any evidence tending to support a given finding, and whether the evidence conclusively establishes a particular fact," both of which "are deemed questions of law." The court concluded that there was sufficient evidence on which the industrial commission could base its judgment and accordingly affirmed the order of the industrial commission denying compensation to the widow.—*Sutfief v. New Richland Produce Co. (Minn.)*, 275 N. W. 692.

Workmen's Compensation Acts: Massage as Constituting "Medical Services."—The employee received an injury to his back and on the recommendation of his attending physician obtained the services of an experienced masseur, who administered treatment under the supervision and control of the physician. In a proceeding under the workmen's compensation act by the employee, the masseur filed a claim to collect the amount due him for the treatment administered. The trial court entered a decree ordering the claim paid, and the insurer appealed to the Supreme Judicial Court of Massachusetts.

An insurer, said the court, under the workmen's compensation act may be required to furnish as part of the compensation to which an injured employee is entitled "adequate and reasonable medical and hospital services, and medicines if needed, together with the expenses necessarily incidental to such services." The words "medical services" have been held to include the services of a nurse or trained attendant rendered under the direction and control of a physician. *Meuse's Case*, 262 Mass. 95, 159 N. E. 636. Where, as in the present case, massage treatments are necessary, are prescribed by the attending physician and are given under his supervision and control they, the court said, constitute "medical services" within the meaning of the workmen's compensation act.

The massage treatments were given more than two weeks after the time of the employee's injury. The workmen's compensation act in its original form required the insured to furnish medical and hospital services only during the first two weeks following an employee's injury. Subsequently the act was amended to authorize the board in its discretion to require the insurer to furnish such services for a longer period "in unusual cases" and in "cases requiring specialized or surgical treatment." The insurer contended that the words "specialized or surgical treatment" should be taken to mean only that type of treatment which can be given by a physician or a surgeon who is a "specialist." In the opinion of the court, however, the words "specialized . . . treatment" do not limit treatment to such as can be given by a physician who is an expert. It is common knowledge, the court observed, that in modern times prac-

titioners of medicine in the treatment of their patients not infrequently call to their aid persons not physicians or surgeons whose experience, knowledge and training enable them to contribute treatment beneficial to the patients. Roentgen and other light treatments, the application of heat, massage, and other treatments by persons specially trained and equipped are often prescribed by physicians to aid in the cure or in the relief of their patients. The court thought that massage prescribed by an attending physician and given under his supervision and control by an experienced masseur was "specialized . . . treatment" within the meaning of the act.

The decree entered by the trial court in favor of the masseur was therefore affirmed.—*Haggerty's case (Mass.)*, 11 N. E. (2d) 583.

Contraceptives: Right of Municipality to Regulate Distribution of Contraceptives.—An ordinance of Knoxville, Tenn., makes it unlawful for any person other than a licensed physician or a registered pharmacist to sell, give away or otherwise distribute "any appliance, drug or medicinal preparation intended or having special utility for the prevention of conception and/or venereal disease." In no event is distribution to be authorized to persons 18 years old and under. The defendant, who operated a small stand from which he sold articles such as candy, chewing gum and razor blades, was convicted of violating this ordinance by selling condoms. He appealed to the Supreme Court of Tennessee.

The defendant insisted that the ordinance was invalid because it gave to a special group of merchants privileges which it denied to others, in violation of provisions in the state constitution. He argued that the handling of condoms does not require any special or technical knowledge. Condoms, he argued, may be compared to "patent medicines" in that they are prepared ready for immediate use and sold to consumers in the original packages, without further preparation or instructions and without the necessity of any special or technical knowledge on the part of the vender.

If, said the Supreme Court of Tennessee, any possible reason can be conceived to justify a classification contained in a legislative enactment, it will be upheld and deemed reasonable. The classification contained in the ordinance under consideration, the court thought, was natural and reasonable. Certainly, the prohibition of the sale of contraceptive goods, except by a licensed pharmacist or by a licensed physician and then only to persons more than 18 years of age, tends to preserve public morals as well as the health and safety of the people of the community. It cannot be doubted that the indiscriminate sale of contraceptive goods by pedlers and vending machines, at stores and filling stations, is a menace to the morals and health of the people. Under the charter of the city of Knoxville (chapter 412, Private Acts, 1923) the city is given broad and full power "To define, prohibit, suppress, prevent, and regulate all acts, . . . and all other things whatsoever detrimental to the health, morals, comfort, safety, convenience or welfare of the inhabitants of the city." The ordinance in question, said the court, is valid and constitutional and accordingly the court affirmed the judgment of the trial court.—*McConnell v. City of Knoxville (Tenn.)*, 110 S. W. (2d) 478.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1927 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Epidermoid Carcinoma in Osteomyelitis.—Harrison reports a case of chronic (eighteen years) osteomyelitis of the tibia with epidermoid carcinoma in the sinuses extending up the anterior, medial and lateral aspects of the leg, with invasion of the soft tissues and bone. Following amputation up to the mid thigh the patient made a striking recovery from an advanced state of general physical debility and cachexia. She is well and without evidence of metastasis two years after operation. When epithelial cells during the process of regeneration are exposed to the products of chronic inflammatory exudate for many years their normal repair is altered to an extent which may eventually result in neoplastic growth. The life history of carcinoma developing in osteomyelitic foci is one of slow progression. In view of the tendency of the tumor to remain localized, a good result may confidently be expected after amputation of the involved limb. Considering the slow growth of the lesion and the failure to metastasize, there may be some doubt as to whether it represents true epidermoid carcinoma. Yet the extensive invasion with replacement of soft tissue and bone must place the neoplasm in that category.

Relation of Smoky Atmosphere to Pneumonia.—Pittsburgh presents an unusual opportunity for the study of the relation of smoke to pneumonia. Haythorn and Meller review the evidence accumulated and add to it the data acquired through the analysis of 3,000 persons dying from various diseases in Pittsburgh hospitals. The examinations were made for the purpose of determining the kinds and extent of the changes in the lungs and the amount of visible deposits of dust. The series represents a cross section of the general inhabitants of the city. The lungs removed at necropsy were graded microscopically for the amount of extraneous pigment and the resulting fibrosis. Grades 0, 1 and 2 appeared to have no particular occupational basis. Grade 3 was a mixed nonoccupational and occupational group. Grades 4 and 5 were largely, although not exclusively, occupational. The incidence of pneumonia, "all forms" and of lobar pneumonia was tabulated in relation to each grade of anthracosis. In spite of the high local death rate from pneumonia, no anatomic evidences of a relation between the incidence of pneumonia and the milder grades of anthracosis could be demonstrated in the nonoccupational groups. In grades 3, 4 and 5 there was a definitely higher percentage of pneumonia, but the average age for each of these grades coincided with the period of life at which the death rate from pneumonia in less smoky communities is likewise highest. Healing by organization of unresolved pneumonia was consistently higher in all of the more advanced grades of anthracosis and greatest in grade 5. The organizing foci appeared to be associated with heavy deposits of pigment, microscopic areas of fibrosis and isolated emphysematous pockets in fibrosed portions of the lungs. Nothing tangible was found to connect the deposits of pigment with the high incidence of pneumonia and high mortality rates, but the association of severe anthracosis and healing by organization formerly reported is verified.

- The Syndrome of Extrarenal Azotemia. H. Jeghers and H. J. Bakst, Boston.—p. 1861.

Grave Sequelae of Blood Transfusions.—DeGowin states that from November 1933 to July 1937 approximately 3,500 blood transfusions were performed in the hospitals of the University of Iowa. Citrated blood was used almost exclusively. It was administered through small needles by gravity. All serious complications resulting from transfusion were studied as thoroughly as circumstances permitted. Most of the transfusions were given with bloods of the same group, although bloods of group O were used occasionally when the homologous group was not available. Seven deaths directly attributable to blood transfusions occurred. Five persons died of renal insufficiency and two of pulmonary edema. Only one person in whom renal insufficiency developed recovered. The importance of using typing serums of high titer is emphasized by the donor in cases 2 and 4, who gave blood as of group O and later, with stronger serums, was found to belong to group A. The necessity for cross matching of bloods in addition to typing is illustrated by two cases in which the recipients were

found to belong to atypical blood groups which were not differentiated by strong typing serums and in which errors apparently occurred in the preliminary cross matching. A transfusion should be discontinued immediately on the occurrence of any unusual symptoms. That the present laboratory tests as routinely applied involving cross matching by the hanging drop, the Vincent open slide and the Landsteiner centrifuge methods are inadequate in certain instances to detect incompatibilities of bloods which after transfusion become manifest clinically is illustrated by one case and the experience of other authors. The various theories to account for the mechanism of renal insufficiency from blood transfusion are discussed. In view of the present ignorance of the mechanism of renal damage it would seem that the only safe procedure at present is to alkalize the urine prior to transfusion. The use of "universal donors" is fraught with danger unless the agglutinins of the donor have been previously titrated and found to be weak. Pulmonary edema from blood transfusion is not the result of the administration of incompatible blood. On theoretic grounds, it would seem to be due to overburdening of the right side of the heart. Patients with cardiac damage and those with nitrogen retention from any cause apparently tolerate transfusions poorly. In patients having diseases which predispose to retinal hemorrhage transfusion is sometimes followed by bleeding into the macular region, causing serious impairment of vision. Necropsies of patients receiving transfusions are occasionally highly instructive if the pathologist is familiar with the morbid anatomy of transfusion reactions. This is especially true in cases of renal insufficiency.

Therapeutic Experiences with Cobra Venom.—The conclusion that Macht draws from various experiments is that cobra venom, like opium and its principal alkaloid, morphine, relieves pain through its action on the higher centers of the brain. While morphine relieves pain promptly and the effect wears off within a few hours, cobra venom does not induce analgesia rapidly but once it is induced the analgesia lasts much longer than that of morphine. Once analgesia has been established, patients may usually be kept comfortable with two or three weekly intramuscular injections of 5 mouse units of cobra venom. The author has personally administered two such injections twice a week to patients with advanced and hopelessly malignant cancers for months in succession and he has been able to keep them comfortable without using any other drug. While cobra venom has been chiefly advocated in cases of hopelessly advanced malignant tumors and their metastases, during the past year or two the author has extended its use to the treatment of certain nonmalignant conditions (severe neuralgias, chronic arthritis and angina pectoris with subacute, long-lasting paroxysms of pain). The number of arthritic cases treated with this drug is still not large enough to warrant discussion, although considerable relief of pain has been obtained in some instances. Cobra venom has also relieved the pain and relaxed the rigidity of the muscles and produced a general amelioration of parkinsonian symptoms in seven cases. The action of the drug in such cases is probably a complex one: (1) The analgesic action of cobra venom certainly plays a part, (2) the anticonvulsant property of the drug may also exert an effect and (3) it is probable that certain peripheral effects of cobra venom described by Cicardo may be involved in the mechanism of its action.

Urticaria.—It seems logical to Rusk and Kenamore that potassium should be a valuable drug in the treatment of edematous lesions of the skin: first it lowers the cutaneous irritability directly and secondly its pharmacologic reaction is similar to and definitely allied with epinephrine. The results in six cases that they report are far from conclusive but definitely indicate the therapeutic response. These patients had been tried on the various allergic regimens and orthodox treatment without success. A sound physiologic and pharmacologic basis seems to exist for the treatment of the various allergic phenomena by further change in the already abnormally altered mineral balance. In cutaneous irritability and cutaneous inflammation the potassium metabolism is markedly altered and an increase in cutaneous potassium causes an appreciable decrease in localized irritability. Potassium is almost identically like

epinephrine in its pharmacologic action. Because of these known facts it seems logical that certain allergic problems could be approached from this therapeutic angle with benefit. A high protein, low sodium, acid-ash diet, with added potassium chloride, has produced promising clinical results in six cases of chronic urticaria.

Postmortem Bacteriology.—Burn and Burket find that cultures of human cardiac blood, viscera and apical tissues of the teeth obtained at necropsies show no significant differences in the frequency of recovery of bacteria from these sites. The greatest difference occurred in the kinds of organisms obtained. *Streptococcus viridans* and *Streptococcus nonhaemolyticus* were predominant among the bacteria recovered from the tissues around the apexes of the teeth. Other kinds were obtained with greater frequency from the blood stream and viscera. *Staphylococci* were procured from both teeth and viscera, in about the same frequency. Only eleven (10 per cent) of the apexes isolated in seven of thirty-eight necropsies on persons with bacteremia had gingival tissue and crowns sufficiently well preserved to suggest that the organisms at the apexes were from the blood stream. *Bacillus coli* was found around the teeth only in the presence of bacteremia. *Streptococcus haemolyticus*, *Diplococcus pneumoniae* and three unidentified organisms were the other kinds recovered from both blood and teeth. Of the fifty-five necropsies on persons with negative blood cultures obtained clinically or after death, eight showed fifteen apexes containing *Streptococcus haemolyticus* or pneumococci. The infections of three of these apexes are known to have been due to invasion by bacteria from the oral cavity. Suggestive evidence that transient bacteremia might occur at times during the life of a subject is indicated in the postmortem isolation of pathogenic organisms from the viscera, although both the clinical and the postmortem blood cultures remained negative.

Effect of Carbon Dioxide on Clotting.—Tannenbergh studied the influence of carbon dioxide on the clotting of blood. Whole blood obtained from various veins and arteries was studied directly after its removal in an apparatus whereby saturation with carbon dioxide was rapidly secured without mechanical disturbance of the blood by the gas. Citrated and recalcified blood and plasma were studied systematically directly after removal and after various periods up to five days. Citrated blood, the gases of which were evacuated in vacuo and which was subsequently saturated with carbon dioxide or oxygen, was also studied. In all these samples, carbon dioxide produced a varying but definite delay of clotting without, however, preventing it. Accordingly, the spontaneous clotting of blood in the heart and large veins of rabbits put to death following periods of inhalation of carbon dioxide was delayed. Acceleration of clotting after short periods of inhalation of carbon dioxide is considered an indirect transient effect of carbon dioxide on the peripheral and central nervous system, producing an enlarged output of epinephrine. Carbon dioxide is considered one metabolic product which physiologically counteracts clotting and thrombosis, especially in the small veins of the liver and kidney. Carbon dioxide may also be largely responsible for

the fact that blood in the capillaries is found liquid after death. This fact had heretofore been ascribed to the influence of the capillary endothelium, for which theory reasonable evidence was never adduced.

Selective Collapse by Partial Thoracoplasty.—Pulmonary tuberculosis is frequently characterized by a large apical abscess, which forms the most intractable focus of the disease. Such an abscess must be closed either by reexpansion of the good lung or by compression. Healing will not occur unless closure of the cavity is effected. For such an abscess Holman and Pierson believe that localized selective collapse is preferable to the usual complete paravertebral thoracoplasty. A limited thoracoplasty may be necessary because of bilateral involvement of the lungs or the necessity for conserving the good lung at the base. The abscess may be displaced rather than compressed by the old fashioned paravertebral procedure. Complete collapse of apical abscesses may be aided by complete resection of the upper three ribs from the transverse process in the back to the costal cartilage in the front, resection of the transverse processes over the site of the abscess and resection of the lower third of the scapula. Revision of inadequate thoracoplasties for incompletely collapsed cavities should not be a repetition of previously ineffectual procedures but should include resection of the transverse processes over the site of the abscess and, when necessary, resection of the anterior stumps of the ribs through an anterior incision. In the presence of bilateral apical abscesses, a unilateral upper thoracoplasty may be effective in relaxing the opposite apex, thus providing better conditions for healing of both abscesses by one operative procedure. Thoracoplasty as a therapeutic measure should not be condemned or abandoned until the offending cavity has been effectually and completely collapsed.

Treatment of Alcoholic Psychoses with Thiamin Chloride.—Up until 1937, when vitamin B extract became available in large quantities, alcoholic psychoses were a serious and unmanageable problem. Since that time it has been possible

to treat such conditions with a great deal of success. Of thirty-six cases that Brodsky treated, thirty-five are apparently cured. It is too early as yet to state definitely whether the cure will be permanent. All the chronic alcoholic psychoses treated were based on a history of alcoholism over a considerable period with hallucinations, particularly of the auditory threatening type, fear and disorientation. The treatment was as follows: (1) the removal if possible of alcohol, (2) daily injections of massive doses of crystalline vitamin B in the gluteal muscle, the dosage being anywhere from 500 to 2,000 units daily and (3) the administration of some such sedative as bromide, chloral and, in some cases, phenobarbital. Prompt improvement was observed in all cases within a period of weeks or months* and an absolute cessation of all symptoms even though they had lasted for some time. There was no recurrence of a desire for alcohol. This peculiarity was noticed also in acute alcoholic psychoses. The acute psychoses were treated with spinal drainage and daily hypodermic injections of vitamin B into the gluteal muscles in small doses such as from 300 to 500 units, and these also showed an improvement and a lack of desire to return to the former habits. The author is at present conducting a series of experiments to determine whether the human brain contains vitamin B normally and whether it is destroyed by alcohol.

Phrenic Interruption in Pulmonary Tuberculosis.—Klein lists the uses of phrenic operations. The object of phrenic interruption is to paralyze the hemidiaphragm. Besides functional rest, phrenic interruption also produces a varying degree of venous and lymphatic stasis, as well as anoxemia, which plays such an important part in promoting fibrosis and encapsulation of tuberculous lesions with diminution of septic absorption from the lung. Phrenic interruption can be brought about by radical phrenicotomy, or exeresis, by simple phrenicotomy and by crushing the nerve fibers. In a series of seventy-five cases in which phrenic interruption was done by the author, forty-five were classified as moderately advanced and thirty belonged to the far advanced group. All but five cases showed

some improvement of subjective symptoms within three months following phrenic interruption. Of the total number of patients fifty-four became definitely improved, as evidenced by closure of the cavity and negative sputum. Of the remaining twenty-one patients all were known to have thick walled cavities, and supplementary operations, such as thoracoplasty, pneumothorax and permanent phrenic interruption, were performed on fifteen patients. Of these six died from extension of the tuberculous process and not as a direct result of the operation. The increased use of temporary phrenic paralysis has considerably widened the scope of its usefulness in the treatment of pulmonary tuberculosis. Having the added advantage of permitting with impunity a subsequent change from a temporary to a permanent paralysis or to supplement it with pneumothorax, temporary phrenic paralysis should be seriously considered when contemplating the first step in collapse therapy.

Regional Ileitis and Ulcerative Colitis.—Stafford compares the etiologic aspects of regional ileitis with those of three cases of ulcerative colitis with lymphogranuloma of the large intestine. The clinical history in each case is not unlike that of a case of regional ileitis, the chief differential point being the presence of a positive Frei test. Under the microscope, in the last of these three, the typical lymphogranulomatous lesion is present and easily differentiated from the nonspecific lesion of regional ileitis. The microscopic appearance of the lesions in the first two cases of lymphogranuloma is not strikingly different from that of regional ileitis. In no case of regional ileitis were any tubercle-like structures found. The presence of a small foreign body in the third case cited is no doubt secondary to ulceration of the mucosa. In lymphogranu-

loma intestinal lesions may occur anywhere in the large intestine. No case has been observed in the Johns Hopkins Hospital, however, in which ulceration due to lymphogranuloma has been found in the small intestine. In the present series of ten cases of regional ileitis the Frei test, when carried out, was negative. The intestinal lesions due to the virus of lymphogranuloma are confined to the large intestine, whereas in regional ileitis the lesions are located in the small intestine. Many cases have recently been reported in which lesions were found simultaneously in the small and large intestines. These should be reconsidered, in the light of the possibility of discovering lymphogranuloma. The clinical features in the two types of cases are similar. The many points of similarity in the clinical course and, to a lesser extent, in the pathologic picture between lymphogranuloma of the intestine and regional ileitis suggest that the lesions of the latter are also produced by a virus infection. Further work with material from regional ileitis must be done to settle this point. Tuberculosis and amebiasis have both been adequately disposed of as possible etiologic factors by earlier writers on this subject.

Human Influenza Virus in Swine.—Shope studied the serums from two age groups of swine on two New Jersey institution farms for their capacity to neutralize the swine and human influenza viruses. The serums from none of the young swine, born since July 1937, neutralized either virus. However, the serums of all the old hogs studied on one farm and three fourths of those on the other farm neutralized human influenza virus, although failing to neutralize swine influenza virus. These older animals had all been born prior to November 1936 and had thus lived through a winter when human influenza was known to have been unusually prevalent. The presence of human influenza virus-neutralizing antibodies in the serums of the older animals was not an age phenomenon, because serums from swine of corresponding ages from other sources failed to neutralize human influenza virus. It is believed that the antibodies in the serums of the older animals resulted from actual infection with human influenza virus and that a widespread infection of human origin had occurred. The failure to recognize either outbreak is not surprising because, even under conditions of experimental infection of swine with large doses of human influenza virus alone, the resulting disease is so mild and ill defined as to be difficult of certain recognition. How the virus was transferred to swine is unknown, though presumably it was either by direct exposure to human cases or through the medium of garbage contaminated by virus. The antigenic compositions of the influenza viruses infecting the swine at Bordentown and Jamesburg were definitely and completely different from that of ordinary swine influenza virus.

Previous to the experiments just described there has been no concrete evidence that influenza virus could be transmitted from man to swine under natural conditions. The present experiments, by demonstrating that human influenza virus of the type prevalent during the winter of 1936-1937 was transmitted to swine under natural conditions, furnish evidence that a similar transmission from man to swine might readily have occurred in 1918.

Acute Anterior Poliomyelitis.—Sako and his associates review the sixty-eight cases of acute anterior poliomyelitis admitted to the University and Minneapolis General Hospitals from July 1, 1937, to Dec. 31, 1937. In all these cases the diagnosis of acute anterior poliomyelitis was made after careful clinical and thorough laboratory investigation. The sex distribution was equal in the series. No evidence has been found to show any correlation between the blood groups and the incidence of poliomyelitis or the severity of paralysis. Paralysis of the muscles of the trunk and abdomen was frequent. Careful muscular tests should therefore be done before the patient is discharged in order to prevent subsequent deformities. The leukocyte count showed no relation to the temperature, the average count being at the upper limit of normal. This suggests that the blood response and presumably the antibody response is slow or absent. The majority of the spinal fluid cell counts were between 50 and 100. The curve of the spinal fluid cell count gradually fell until the onset of paralysis, when it rose again and then gradually fell. The polymorphonuclear count gradually decreased as the disease progressed, and the mononuclears correspondingly gradually rose until about the fourteenth day, when they reached practically 100 per cent. Repeated spinal punctures have revealed that many patients with definite clinical meningeal involvement or even paralysis may have normal spinal cell counts which subsequently may or may not become elevated. The course of the disease cannot be predicted by the temperature, spinal fluid observations or

the erythrocyte count. Convalescent human serum administered in the preparalytic stage was not effective in preventing paralysis nor did it cause any improvement in the paralytic cases so treated. Results tend to indicate that normal adult serum is the treatment of choice at the present time. Sulfanilamide administered in large doses to seventeen patients was found to be of no help. The use of respirators should be given preference in intercostal or diaphragmatic paralysis in which this form of treatment is most effective. In bulbo-spinal cases with unilateral pharyngeal paralysis the patient may be saved if the paralysis does not progress. In pure bulbar cases, the respirator is not indicated and possibly is contraindicated.

Excretion of Bismuth After Injection.—The urinary and fecal excretion of bismuth after intramuscular injection of sodium bismuthate soluble (sobisminol) in therapeutic doses in animals and patients was observed by Hanzlik and his collaborators to be similar to that of water-soluble products of bismuth in general. Daily fluctuations in urinary excretion of bismuth were smaller after small doses than after multiple doses of sodium bismuthate soluble; peak of excretion occurred generally on the second or third day after the last injection and the excretion was well sustained, lasting at least one month after from three to twelve doses of sodium bismuthate soluble. Daily fecal excretion of bismuth fluctuated considerably. It amounted to about one eighth or one tenth of the urinary excretion. Sometimes it outlasted the urinary excretion and tended to last longer than after other soluble bismuth products. From 60 to 70 per cent of injected sodium bismuthate soluble was left unaccounted for in the bodies of both animals and patients. This body bismuth is presumably excreted in minute traces over long periods—a desirable state for efficient anti-syphilitic treatment. Consistent with an accumulation of bismuth in the body was a comparatively long duration of bismuth excretion and late presence of bismuth in some bloods and cerebrospinal fluids. The solution was satisfactorily tolerated intramuscularly in both animals and man.

Etiology of Lung Abscess.—Freedman selected a total of 447 cases in which the diagnosis of abscess of the lung was made at one time and all proved cases of abscess of the lung for comparative study. Roentgenograms were examined and histories and necropsies were studied. The total of cases accepted for investigation was 276. These were then separated into those of postoperative origin and those with other causes;

196 cases were of medical origin, seventy-six occurred as a postoperative complication and four were a result of trauma. Although it has become the general belief that postoperative complications are predominating factors, this was not the fact in the present cases. A careful investigation in other large clinics should produce similar results. Tonsillectomy is a prominent cause in a large number of cases, largely because it is more frequently performed than any other operation. However, when compared to the total number of operations performed it represents a smaller percentage than is generally realized and compares favorably not only with the incidence following pneumonia but also with that following other postoperative conditions. Nearly all the cases of abscess of the lung after tonsillectomy occur in adult patients, indicating that these patients require more careful selection and preoperative care and better postoperative attention than heretofore recognized. A more careful examination before all operative procedures and more careful postoperative observation will considerably lessen the incidence of postoperative abscess of the lung. A large proportion of abscesses of the lungs are still due to acute and chronic pneumonic processes and in all probability outnumber those occurring as postoperative complications.

Ulcerative Enterocolitis in Tuberculosis.—Granet and Ornstein made 2,416 examinations on 2,088 patients with pulmonary tuberculosis for the presence of ulcerative enteritis, of which 800 presented definite evidence of enterocolitis. Of patients with positive x-ray evidence of ulcerative enteritis, only 29 per cent had subjective gastrointestinal symptoms. In patients with pulmonary tuberculosis with positive sputum, it is futile to wait for the development of gastrointestinal symptoms in order to establish the diagnosis of complicating ulcerative enterocolitis. A simple barium sulfate examination at seven hours is practical and accurate. A favorable result can be expected from early diagnosis and prompt treatment. Successful treatment of intestinal tuberculosis depends on inactivation of the source of infection in the lungs. Absorption of toxins from active lesions of the lung, by their noxious systemic effect, prevents healing of intestinal lesions. The treatment of the intestinal lesions is general and specific. The general measures include actinotherapy, a high caloric, low roughage diet, the administration of vitamins C and D, iron for secondary anemia, calcium salts and, when indicated, insulin to stimulate appetite. Specific local treatment is directed primarily toward fostering peristaltic rest in the involved segments of the intestine. A smooth, low residue, high caloric diet, to which is added tomato juice and cod liver oil, reduces peristaltic action to a minimum and provides an excess of vitamins C and D. Abdominal pain is controlled by heat or adequate sedatives. Constipation is helped by small amounts of liquid petrolatum or by gently administered warm sodium chloride enemas. Diarrhea is controlled by the frequent administration of 15 Gm. barium sulfate or kaolin and, if necessary, tincture of deodorized opium in effective doses. Surgical intervention has definite indications in the treatment of certain types of intestinal tuberculosis. Granulomatous lesions should be resected. Operative delay may be costly in acute tuberculous appendicitis. Operative delay in perforation of tuberculous ulcers with resulting peritonitis is fatal.

Urogenital Tuberculosis in Children.—Campbell believes that by more frequent complete urologic examination in young patients with so-called chronic pyelitis the true incidence of surgical tuberculous renal infection will be found much higher than the present collected data indicate. Exposure to active pulmonary tuberculosis is probably a more important etiologic factor than infection by milk. The renal infection is always secondary to a tuberculous focus elsewhere. When urogenital and skeletal tuberculosis coexist, they may be assumed to be secondary to a common primary focus. The usual urinary symptoms of renal tuberculosis in children commonly lead to the diagnosis of chronic pyelitis and, because symptoms referable to the bladder are the chief complaint in more than three fourths of the cases, cystitis is usually incorporated in the diagnosis. Tuberculosis of the epididymis is practically always secondary to renal tuberculosis. Although genital tuberculosis is uncommon in the young, it must be considered in the differential diagnosis of scrotal swellings. It is unimportant whether the epididymal infection is primarily hematogenous or results from secondary extension from a tuberculous prostate or seminal vesicle, in turn secondarily infected by urine from renal tuberculosis. The disease involves the epididymis primarily; true tuberculous orchitis is almost always a secondary invasion from a caseous epididymis. Epididymectomy is the treatment, yet orchidectomy must be performed when the testicle is secondarily involved. Tuberculous scrotal fistulas must also be excised with the epididymis. Heliotherapy and tuberculin therapy may be of supportive value but should not be relied on to cure the epididymitis. If the prostate is also tuberculous, the vas deferens on the opposite side should be divided between ligatures to prevent tuberculous extension to that epididymis. The symptoms of prostatic and seminal vesical tuberculosis are predominantly those of acute or hyperacute cystitis and result from intense inflammation of the overlying mucosa of the vesical trigon and outlet and of the posterior urethra. Since prostatic and vesicular tuberculosis are associated with or are secondary to renal invasion above or epididymal invasion below, amputation of the involved kidney or epididymis or both is the initial surgical procedure.

Cutaneous Metastasis in Breast Cancer.—According to O'Brien, in a period of fourteen years (1923 to 1936) 407 cases of pathologically proved cancers of the breast were operated on at the Boston City Hospital. Of these 255 were treated postoperatively by x-rays. Single or multiple cutaneous nodules appeared in fifty-four of these 255 cases. In twenty-two cases cutaneous metastases appeared on an average of 8.14 months after operative intervention, which was frankly incomplete. In thirty-two cases cutaneous metastases appeared on an average of 14.6 months following the classic radical resection. There were ten of these cases, however, in which palpable axillary and supraclavicular glands were present before operation and the radical operation should not have been done. Cutaneous metastases did not appear for an average of 18.5 months in the twenty-two cases in which palpable nodes were absent and radical operation was performed. These statistics indicate that the appearance time of cutaneous metastasis in this group of breast cancers treated postoperatively by x-rays was directly related to the extent of the growth at the time of operation. There was no evidence that the kind of tumor influenced the appearance time of cutaneous metastases. However, cutaneous metastasis appeared with relative promptness following incomplete or injudicious surgery. If postoperative irradiation is of any value in inhibiting cellular growth and the distribution of cancer emboli, preoperative irradiation ought to be of greater value, for with the breast and axilla intact, larger amounts of radiation may be administered to these areas without damage to the wall of the chest and axillary vessels.

Spontaneous Pneumothorax.—Ehrlich and Schomer advance a theory of idiopathic spontaneous pneumothorax which depends on the location of a visceral pleural defect during natural "wear and tear." It is based on the assumption that, no matter what the cause of pleural and lung laceration, the location is what determines whether or not pneumothorax takes place. The size of the laceration is not a determining factor. If the tear involves bronchi, bronchioles, respiratory bronchioles or even alveoli lining the wall of a respiratory bronchiole, the atmospheric pressure in the trachea and bronchi by fairly direct communication exerts sufficient force to drive air into the pleural cavity and cause a pneumothorax. On the other hand, a laceration may involve numerous intercommunicating alveoli and not produce a pneumothorax. The authors are of the opinion that in normal respiration the gliding of the visceral over the parietal pleura causes a continuous shedding and regeneration of the pleural mesothelium. A slight defect in the regeneration at some point, if located in a portion of a lung lobule or lobules involving one or more bronchioles, will, when accompanied by a respiratory effort of greater or lesser severity, cause a tear in the visceral pleura and a

pneumothorax will follow. Of course the lack of probability of such an accident in this location is what makes true "idiopathic" spontaneous pneumothorax of rare occurrence. Sudden sharp pain in one side of the chest accompanied by increasing dyspnea and possibly collapse suggests spontaneous pneumothorax; physical signs and x-ray examination corroborate it. Prognosis is much better in the open and closed types. The valvular type causes the most severe symptoms, and owing to the treatment necessary makes this type more prone to complications; e. g., serous or purulent effusion. Uncomplicated spontaneous pneumothorax without distressing symptoms requires only rest and symptomatic medication. If dyspnea becomes severe and the side of the pneumothorax is greatly distended with air, as is almost always the case in the valvular type, deflation should be resorted to.

Undulant Fever Treated with Sulfanilamide.—Toone and Jenkins report the cure of a case of undulant fever (*Brucella abortus*, suis strain) in a Negro male patient. The diagnosis was confirmed by blood culture, agglutination and the *Brucella abortus* opsonophagocytic index. A rapid fall in temperature to a normal level associated with symptomatic improvement and negative blood cultures followed promptly after the administration of 450 grains (29 Gm.) of sulfanilamide over a period of eleven days.

Relationship of Porphyrinuria to Human Pellagra.—Spies and his associates believe that an increased excretion of porphyrin in the urine of twenty pellagrins, irrespective of the presence of dermatitis, indicates that increased porphyrinuria is an integral part of the syndrome of pellagra. The increased porphyrinuria does not parallel the severity of the clinical manifestations of pellagra. In this study it reached a peak in the majority of cases early in the course of the disease and in four cases the porphyrin excretion returned to normal despite the fact that the patients ate only a basic diet. Coproporphyrin 1 and 3 have been isolated from the urine in two classic cases of pellagra. It appears that an inadequate amount of nicotinic acid may impair hepatic function, which is followed by an abnormal formation of coproporphyrin 3. It would seem that the following working hypothesis might be advanced tentatively: In the absence of nicotinic acid the function of the liver is

impaired and coproporphyrin 3 is formed. This coproporphyrin is an abnormal product of porphyrin metabolism and is a sensitizing agent. Clinical observations show that certain pellagrins with large amounts of porphyrin in the circulation are not affected by prolonged exposure to the sun and that when there is a sensitizing effect it varies greatly with the individual patient.

Treatment of Chronic Otitis Media.—Donnell ceased the use of watery irrigation in the treatment of acute or chronic infections of the ear. The so-called dry treatment avoids many of the objections to watery solutions. The objection is not alone the soggy condition of the external canal but also the fact that many of these infections are kept active by the irrigative solution in the middle ear. The dry treatment is carried out by the use of cotton wicks. The wicks are changed as often as one fourth of their length is wet. It may be necessary to change them every ten or fifteen minutes if the discharge is profuse. If it is felt that one must irrigate an acute or chronically infected ear, it is best to use 70 per cent alcohol. Most chronically infected ears will heal if kept clean. Pratt in 1930 suggested what may be called "continuous drainage" by the use of cotton wicks. His method is to roll cotton on an applicator and clean the ear and then cotton in the form of a wick is left in the canal a little distance from the tympanum and replaced as often as it is soiled. The cotton wick should be long enough to rest comfortably on the tympanum and to protrude far enough from the external canal to be removed easily. It should not be large enough to fill completely the canal, as that would tend to make a soggy condition of the membrane and canal, which would be inimical to healing and could possibly cause furunculosis. About six years ago the author began the use of vitamins in the treatment of all chronically infected ears. Halibut or cod liver oil, to the equivalent of three or more teaspoonfuls of standard cod liver oil, and from three to six brewers' yeast tablets a day with the addition of orange or lemon juice to the diet have been used. The results have been satisfactory. With the wicks, which by capillary attraction are a form of continuous drainage, and the vitamins, infected ears have healed and a secondary membrane has formed when all other conservative means of treatment have failed.

Posture and Drainage of Tracheobronchial Tree.—Vinson believes that the most satisfactory method of drainage by posture is to have the patient kneel on the edge of a chair or low table and place his hands on the floor. In this way the trachea is so inverted that secretion in the lungs descends by gravity. In many instances large quantities of sputum will be expelled by such change in position. The benefit following drainage by gravity is sufficiently uncertain to make it inadvisable for patients who have tuberculous lesions or who are seriously debilitated. Pulmonary abscess usually is associated with a stricture in the bronchus communicating with the area of infection in the lung and, until this stricture is dilated to permit the flow of pus, change in posture will not be beneficial. After the stricture has been dilated, change in posture to promote drainage is seldom required. In chronic bronchiectasis, drainage of the lungs by posture may be helpful in reducing the amount of fetor of the secretion and in limiting expectoration to convenient periods of the day. But when bleeding is occasioned by postural drainage it should not be employed. The time of drainage should always be before meals and before retiring at night. If postural drainage is attempted after meals, vomiting may occur. A few patients with bronchiectasis may find that the flow of secretion from the lung does not begin until after breakfast, in which case inhalation of steam for ten or fifteen minutes will promote drainage. Regular postural evacuation of the tracheobronchial tree will lessen absorption of secretion, reduce the odor of the sputum and limit the cough and expectoration to convenient periods of the day. This treatment will not cure bronchiectasis, but it enables a patient to work with others without odor to his breath and without constant cough, which arouses the suspicion of tuberculous disease.

Chronic Nontuberculous Lung Infections.—Skavlem believes that it is a grave mistake to treat any patient for tuberculosis because of chronic cough, expectoration and blood spitting, in the absence of positive tuberculous sputum, unless the possibility of other causes has been carefully considered and disproved. With such differential studies in mind he discusses other chronic infections of the lungs. These include bronchiectasis, bronchial dilatation, functional disturbances, cough, congenital cystic disease, abscess, distention of the bronchus, gangrene, syphilis, mycotic infection and tularemia.

Cevitamic Acid in Bronchial Asthma.—In view of certain evidence that cevitamic acid may play a part in allergic conditions, particularly asthma, Hunt dispensed cevitamic acid in tablets of 50 mg. to twenty-five asthmatic patients. Other allergic symptoms were present in seventeen cases and chronic bronchitis in nine. The patients were instructed to take two of these tablets daily. During this treatment no medicine or injections such as vaccines were given, apart from antispasmodics or medicine for a troublesome cough. No evidence could be found of any marked improvement in the amount of wheezing, the incidence of attacks or the general condition. None of the five patients (other than the twenty-five) who received intramuscular injections of 500 mg. or more of the acid experienced any relief in their symptoms after a period of from twenty to thirty minutes, and the amount of epinephrine subsequently required to relieve the spasm was in no way diminished. Thus it was impossible to confirm the statement of Hochwald (1936) that asthmatic symptoms could be relieved by large intravenous injections of cevitamic acid.

*Myocardial Infarction: Pathologic Study. R. M. M. Lyon.—p. 285.

Myocardial Infarction.—Lyon reviewed the necropsy records of 3,200 consecutive cases in the Royal Infirmary during the period from 1931 to 1935 and found evidence of a definite myocardial infarct in 110 instances. Certain cases showed recent infarcts, while others had the fibrous scars of previous large infarcts, sometimes causing aneurysm of the ventricular wall. The incidence of infarction in the postmortem room was found to be 3.44 per cent. The sex incidence was seventy men and forty women. The average age of the patients at death was 61.21 years. Twenty-nine of the subjects died of some other disease and their myocardial infarction did not appear to have contributed materially to their deaths. The infarctions in women occurred at a slightly later age period. Syphilitic aortitis was present in eight out of seventy men but in only one woman, and

in this case the coronary vessels were not involved by the syphilitic process. Only eight patients had had diabetes, but there was a female preponderance of five cases to three. No other disease, apart from arteriosclerosis, appeared to be related to the occurrence of infarction. The 110 patients showed a total of 122 infarcts, twelve patients having two separate infarcts. Only five of the 122 infarcts were of the right ventricle. Pericardial friction, when present, is one of the important clinical signs of an infarction. Seventy-three of the patients were carefully examined at the time of their infarction and daily afterward. If the thirteen dying within twenty-four hours are excluded there remain sixty patients in whom friction might possibly have been heard. In only nine cases (15 per cent), however, was friction detected. Friction should be looked on as an important diagnostic sign if present, but its absence should not negate the diagnosis of infarction. Approximately half of the patients died within one month of their acute attack.

Insulin Therapy in Schizophrenia.—Although the metabolic observations in schizophrenia are not absolutely specific, Freudenberg believes that the following hypotheses concerning its basis and the mechanism of cure can be regarded as established. In schizophrenia there is probably a primary disturbance in cerebral respiration, perhaps due to some lack of oxygenating substances. This disturbance leads to a collection of toxic products, probably originating from the metabolism of protein. Insulin therapy induces the oxybiotic processes necessary for detoxication and also an irritation of the cell membranes, which results in an increased exchange between the cells and their surroundings. Similar but more sudden changes take place in metrazol therapy. Improved cerebral oxidation and the alkalosis occurring during hypoglycemic coma may be two factors of great importance in the recoveries seen after insulin therapy.

Plaster Splints in Arthritis.—Kindersley lists three main principles that underlie the treatment of arthritic joints: rest, maintenance of such a position of the joint as will allow the least strain on the surfaces of the joint and maintenance of an adequate range of movement. There is no more satisfactory way of procuring rest than by adequate splintage. A perfect splint

is the only method of maintaining the best possible function with the least strain. Adequate range of movement, with removable plaster of paris splints, can be achieved by a daily exercise of the joint.

Plasma for Immunologic Procedures.—According to Burdon, the two circumstances that favor the use of plasma for immunologic tests are that a specimen of plasma may be secured more easily and more rapidly than a specimen of serum (since waiting for the separation of serum from the clot is unnecessary and even centrifugation may be avoided) and that plasma has a demonstrably higher content of antibody than serum from the same individual. The specific reactivity of plasma is interfered with in the fresh unheated specimen, but heating at 56 C. for only ten minutes is sufficient to remove the disturbing factors and to bring out the full specific activity. After the heating, brief centrifugation is all that is necessary to make the specimen of plasma ready for testing. Tests for syphilis on plasma by the Kline microscopic technic or by the Kahn method are as simple to perform and as reliable as the usual tests on inactivated serum, and they may be carried out in much less time. There is a close agreement in the reaction of the serum and the plasma of the same individual in Kline and Kahn tests, but plasma shows a consistent tendency to give a stronger reaction than the corresponding serum. The sensitivity of the reactions of plasma is not likely to lead to false conclusions but, on the contrary, it may be distinctly advantageous in the diagnosis of early syphilis and in following the effect of therapeutic procedures. The increased reactivity of plasma over that of serum of the same individual is not due to the presence of the sodium citrate in 0.1 per cent concentration in the plasma.

*Enteric Fever Treated with Suprarenal Cortex Extract and Vitamin C Intravenously. Najib-Farah.—p. 777.

Porphyrinuria Following Sulfanilamide.—Rimington and Hemmings examined the twenty-four hour specimens of urine for their content of porphyrin from patients receiving sulfanilamide, and abnormally high values were recorded in nearly every case. Sulfanilamide administered to healthy white rats in doses averaging 0.307, 0.278 and 0.079 Gm. per rat daily for periods up to thirty days also gave increase in urinary and fecal porphyrin excretion in each instance; values as high as ten times the normal were recorded. The animals had polyuria during the first days after dosing was instituted and declined somewhat in weight. No other signs of toxicity were observed. The presence of a slight degree of photosensitivity was determined as the result of exposure to ultraviolet rays. The symptoms of acute porphyrinuria bear some resemblance to those reported as a result of sulfanilamide intoxication. The relative proportions of series I and III porphyrins may prove helpful in explaining individual idiosyncrasies toward the drug, especially as regards the manifestation of sulfanilamide rash or dermatitis. When administration of the drug to rats is discontinued a slow return of the urinary porphyrin figure toward the normal level occurs, but this may take several weeks. Animals killed at the height of sulfanilamide dosing present only a slight degree of histologic abnormality in the liver and kidneys, but the spleens are of a blackish brown, much engorged and show extensive deposits of a greenish brown granular pigment, much stainable iron and a certain amount of porphyrin (observed fluoroscopically). The histologic picture had not returned to normal within twenty-eight days after dosing of sulfanilamide was discontinued. The

available evidence would suggest that a certain degree of destruction of blood cells is caused by sulfanilamide in the doses employed. The disturbance in the metabolism of pigment is not to be explained by this fact alone. A more deep-seated effect on the hemopoietic system is suspected, analogous, possibly, in some ways to the toxic action of lead.

Adrenal Cortex Extract and Vitamin C in Enteric Fever.

—Experimental and pathologic observations prove that the endocrine system, particularly the adrenals, has a defensive role in infection. As soon as the diagnosis of enteric fever is established, Najib-Farah begins to give intravenous injections of adrenal cortex extract, in doses between 5 and 20 cc., according to the age and state of the patient, with from 500 to 1,000 mg. of vitamin C. The two products are mixed in the same syringe, since they seem to be more active when injected together. During the same day two more doses of 500 mg. of vitamin C are injected at intervals of four hours; no oral medication is given but an ice bag is applied to the abdomen and occasionally to the head until the temperature falls. Administration of adrenal cortex extract and vitamin C is continued for from five to twelve days and is followed by two intravenous injections daily of 500 mg. of vitamin C alone for at least seven days. In fifteen cases of confirmed enteric fever (seven typhoid, three paratyphoid A, five paratyphoid B) and three cases of acute *Bacillus coli* infection which were treated in this way, the results were with one exception immediately favorable, the exception being a moribund patient with typhoid to whom this treatment was given as a last resort. The injections produce no pain, shock or reaction. There is abundant urination and a gradual fall of temperature to normal between the third and seventh days. Symptoms disappear rapidly, except perhaps the cough, which may need an expectorant, and the patient is soon able to take nourishment. In one case vomiting persisted after the fall of temperature but was stopped by subcutaneous dextrose-saline solution and in two toxic cases dextrose-saline solution had to be given to maintain the sodium equilibrium and to avoid dehydration.

"Alcoholic" Beriberi.—Price cites a case of cardiac failure with polyneuritis in an alcoholic addict. It is similar to those in the acute group (secondary beriberi with severe cardiac failure in alcoholic addicts) described by Weiss and Wilkins in 1936. The cases appear to bear a sufficiently close resemblance to "wet" beriberi of the orient to warrant the belief that they share with it a common pathogenesis. The term "alcoholic" beriberi seems an appropriate and convenient title for the condition. The patient recovered completely after treatment by rest, a high calory diet and large amounts of vitamin B. The clinical features of value in diagnosis include reversible cardiac enlargement, shortening of the electrocardiographic conduction periods and a positive Aalsmeer test due to the morbid sensitivity of the circulation to epinephrine. The multiple factors concerned in the evolution of alcoholic beriberi include defects in diet and assimilation acting in conjunction with increased tissue requirement of vitamin B₁ due to an increase in rate, or alteration in type, of metabolism.

Effect of Anti-thyrotropic Serum on Action of Human Thyrotropic Hormone. C. L. Cope.—p. 888.

Schick Reaction and Circulating Diphtheria Antitoxin.—Parish and Wright confirm the observations of Jensen and others that there does not exist a fixed antitoxin titer (the "Schick level") above which persons are Schick negative and below which they are Schick positive. Nevertheless, there is a much higher level of circulating antitoxin in groups of Schick-

negative than in groups of Schick-positive persons. One hundred and fourteen persons undergoing a course of immunization, many of whom were expected to have "borderline" immunity, were Schick tested. Blood samples were taken immediately before the Schick test and revealed a wide zone of circulating antitoxin values corresponding to positive, negative and doubtful Schick reactions. Similar tests were made with "multiple Schick toxins," sixty-one persons being tested with fourfold and thirty-nine with tenfold reagents. Negative reactions to the fourfold reagents were obtained in persons with as little antitoxin as from 0.002 to 0.0005 unit and to tenfold reagents with as little as from 0.01 to 0.002 unit per cubic centimeter. Pseudoreactions with fourfold and especially with tenfold reagents tended to make readings difficult and to produce discomfort in protein-sensitive persons. The routine use of these preparations cannot therefore be recommended. The Schick test has been of proved value in many immunization campaigns, but a negative reaction may not indicate in all cases a state of immunity sufficient to withstand attack by virulent gravis or intermediate strains. To maintain a sufficiently high "level of immunity," the periodic injection of prophylactic into Schick-negative as well as positive reactors may be considered advisable.

Sulfanilamide for Chancroid.—Hanschell treated his last twenty cases of chancroid with sulfanilamide. Each patient received deep subcutaneous injections of 5 cc. of a solution of prontosil soluble, and one or two further injections of 10 cc. at intervals of three days in addition to prontosil album by mouth in divided doses, 3 Gm. in twenty-four hours. There has been rapid healing of the ulcer without leaving the old precipitous-edge scar and rapid subsidence of the bubo in from five to ten days.

Urea Concentration Test and Renal Function.—Krieger has established that, when the normal concentrating power of the kidney is found in association with a small secretion of urine after 15 Gm. of urea has been given, the total amount of urea excreted in the three hours of the test gives a more satisfactory measure of renal efficiency than the percentage concentration of urea in any of the single hourly specimens in the MacLean urea concentration test. The possible combinations of total urea excreted in three hours in relation to the volume of urine secreted are as follows: Normal total urea excreted in a normal, small and large volume of urine in three hours and a small total urea excreted in a normal, small and large volume of urine in three hours. An analysis was made of the 703 urea concentration tests from 437 pregnant patients. The standard of normality used for this classification was that at least 4 Gm. of urea must be secreted in from 150 to 300 cc. of urine during the three hours following ingestion of 15 Gm. of urea in 100 cc. of water. From a consideration of the clinical data presented it is evident that there is agreement between the clinical condition of the patient and the renal efficiency assessed by the total excretion of urea in the MacLean test. More than 50 per cent of the tests on patients in severe and prolonged toxemias exhibited renal inefficiency in the antepartum period. In the puerperium a greater percentage of patients with poor renal function were again found among the toxemic patients. The total number of tests in which the total excretion of urea in three hours aided in determining kidney function was seventy-nine previously termed normal and shown to represent inefficiency and forty-five in which the efficiency was "uncertain" and which have been definitely established as "inefficient." By modifying the interpretation of the MacLean urea concentration test so that efficiency is determined by the total excretion of urea, 17.6 per cent more tests were shown to indicate renal inefficiency

than when the concentrating power was used as the determining factor. Among the normal pregnant patients 69 per cent of tests fell in the normal groups and 20 per cent in the groups indicating renal inefficiency. In the severe toxemias (preeclampsia, nephritis and eclampsia) only one third to one fifth of the tests showed normal renal function and from one half to two thirds indicated renal damage. Among the less severe toxemias (albuminuria) the highest incidence of "doubtful" results occurred. The incidence of tests indicating normal function or renal damage is thus in agreement with the severity of the toxemia in this series of results obtained under entirely different experimental conditions from those described earlier. Renal damage is indicated (1) when a low percentage of urea is excreted in a small volume of urine resulting in a low total excretion of urea in three hours, (2) when a low percentage of urea is excreted in a large volume of urine but the total excretion of urea in three hours is low, (3) when a normal percentage of urea is excreted in a small volume of urine so that the total excretion of urea is low, and (4) when the percentage of urea for one of the three hours is normal or high, but excreted in a small volume of urine and the percentages of urea in the two remaining samples are low so that the total excretion of urea in three hours is low. When a small percentage of urea is excreted in a large volume of urine so that the total excretion of urea is normal or high, the interpretation is uncertain.

*Erythrocyte Sedimentation Rate in Pulmonary Tuberculosis. A. Rest.—p. 307.
Further Studies on Methods of Desensitization of Tuberculous Guinea Pigs. J. D. Thayer.—p. 313.

Sedimentation Rate in Pulmonary Tuberculosis.—Rest studied 4,867 sedimentation tests on 944 patients with pulmonary tuberculosis from 1926 to 1935. He draws the following conclusions: 1. The erythrocyte sedimentation test is of no diagnostic value. 2. The sedimentation rate is of no value in diagnosing the extent of the pulmonary lesion. Although almost all the nontuberculous patients and those with lesions of minimal extent fell within the low sedimentation groups, many of the patients in the low groups suffered from far advanced disease. A low sedimentation rate in a patient with definite pulmonary tuberculosis generally indicates the presence of an inactive, non-progressive type of chronic fibroid tuberculosis. In a small number of patients a normal sedimentation rate does not definitely exclude activity; but definite and pronounced clinical activity and persistently low sedimentation rates are rare. Usually the sedimentation rate becomes markedly accelerated. 3. In the presence of clinically demonstrable tuberculosis, acceleration of the sedimentation rate definitely indicates, or at least strongly suggests, active and progressive disease. It indicates that the body has been severely damaged by the disease. There was a slowing of the rate in some far advanced rapidly progressive cases, probably because of anergy. Occasionally, high sedimentation rates occur in patients with little if any evidence of clinical activity. As a rule, however, this foreshadows the eventual onset of symptoms of activity and progression of the lesion. 4. Slowing of the sedimentation rate, or a return to a normal level, is a striking and, in the majority of patients, a usual accompaniment of clinical improvement and subsidence of symptoms and signs, especially those of toxemia. The sedimentation rate is an index of the condition of the patient at that time. It is of considerable value in prognosis. It was found that the number of deaths increased with the degree of acceleration of the sedimentation rates. 5. The test is of considerable significance in the treatment of patients in regard to rest and exercise. Patients with a persistently high sedimentation rate should be kept more strictly at rest than those with fairly normal rates. 6. The sedimentation rate is of no value in the differential diagnosis between pulmonary tuberculosis and other pulmonary diseases. With the help of the test one can differentiate between an inflammatory or a noninflammatory benign process, but the etiology of the lesion cannot be determined. Pulmonary abscess, gangrene and tumor show accelerated sedimentation rates without characteristic differences from those found in pulmonary tuberculosis.

- Lymphatics of Pyloric Portion of Stomach. C. Rohlich.—p. 401.

Scarlet Fever with Ulceronecrotic Sore Throat.—Angheliesco and his associates made anatomopathologic studies in seven cases of scarlet fever associated with ulceronecrotic sore throat. The tissues were fixed with 10 per cent solution of formaldehyde, with Bouin's fluid, with alcohol; the paraffin sections were stained with hematoxylin-eosin according to the methods of Nissl, Giemsa, Gram and others. In summarizing their observations the authors say that in the sphere of the nervous system the most important lesions are those in the cervical sympathetic chain. The other parts of the nervous system present lesions characteristic of severe toxemia. The lesions of the lymphoid system are general and important. In the posterior part of the throat they have the aspects of hyperergic inflammatory lesions. The "reaction" of the histiocytic apparatus, such as it is, shows microscopic changes with the aspects of a deep lesion with sideration of these elements. Of the endocrine glands the adrenals are the most severely involved. Recent experimental studies demonstrated the repercussions which the toxic lesions of the sympathetic nervous system have on the morphology and functions of the lymphoid organs and of the endocrine glands. Attempts have been made to ascribe an important role in the physiopathology of scarlet fever to the sympathetic nervous system, particularly the nervous centers of the sympathetic ganglions. The authors think that their anatomopathologic observations can be taken as an argument in favor of this interpretation. They believe that in cases of scarlet fever with ulceronecrotic sore throat the clinical and anatomopathologic type is produced by latent lesions of the lymphoid organs and particularly by the nervous elements of the cervical chain. These lesions are due to repeated infections during earlier periods. The authors emphasize that their patients were of the adenoid type, the previous history disclosing infections of the cervical lymphoid organs. The lesions which they detected in the sympathetic nervous system become the anatomic basis to which certain authors apply the term constitutional fragility of the neurosympathetic apparatus. On this anatomic basis the clinical type characteristic of scarlet fever with ulceronecrotic angina develops. Although it may be difficult to affirm at the present time the importance of the effects of the sympathetic centers in the defense against intoxications, the question may be raised whether the alterations of the sympathetic nervous system, such as those observed by the authors, are not at least partly responsible for the insufficiency of the defensive processes of the organism.

- Electrocardiographic Study of Carotid Sinus Reflex. J. Lenègre.—p. 421.

Terminal Endocarditis in Old Rheumatic Endocarditis.—Dumas directs attention to the relations between infectious endocarditis and rheumatic endocarditis, pointing out that some authors are of the opinion that the two disorders have a common etiology. The disease of Bouillaud and the disease of Osler are regarded merely as two different forms from the same infectious state directed by *Streptococcus viridans*. It acts by its toxins in the first case and it is detected by hemoculture in the second. A number of authors, especially

Americans, have demonstrated *Streptococcus viridans* in repeated blood cultures in numerous cases of Bouillaud's disease. After pointing out that Weil and his collaborators reported three cases which favor this theory, Dumas presents four carefully studied cases, in three of which a necropsy was performed. One of these observations does not favor the theory of the common origin, because the port of entry of the infection that was superimposed on an old stabilized mitral endocarditis was brought into evidence with incontestable certainty, in that the infectious symptoms appeared following an abortion. In two other cases, however (the second and third), the transition was unnoticeable between the rheumatic crises of Bouillaud's type with negative hemocultures and favorable modification by sodium salicylate, and the last crises, which developed many years after, gave positive streptococcus hemocultures and had a fatal outcome. The necropsy revealed in these two cases exuberant vegetations of a recent type grafted on old, articular lesions, which certainly were contemporary with the first attacks. The fourth case described by the author raises the problem of an intestinal port of entry of the infectious agent, but here, as in the preceding observations, the transition between the evidently rheumatic crises of the early period and the crises of the infectious type during the terminal period does not permit final conclusions. The author points out that rheumatic endocarditis is a frequent disorder, particularly in its chronic form. It often becomes established after the multiple rheumatic attacks of childhood and adolescence, but in a number of cases its further development ceases after a certain time. There are many persons with mitral or aortic defects who lead an almost normal life and often reach an advanced age. Moreover, it is generally accepted that the lesions of rheumatic endocarditis are chiefly articular, retractable, old and nearly always cicatricial, whereas in the small number of subjects who much later (after ten, fifteen or twenty years) have an infectious endocarditis the lesions are quite different, without connection with the earlier ones and consisting of ulcerative processes or of vegetations that are superimposed on the old cicatrized ones. The author thinks that in view of this difference in the lesions and the difference in the clinical course, first of the rheumatism and later of the infectious state, it is impossible to speak of a common cause. In the reported cases the rheumatism of Bouillaud's type took on the aspects of Osler's disease after many years (twenty years average). This is the reason why, without deciding beforehand whether or not there is a common cause, the author designated this special type of endocarditis as "terminal infectious endocarditis."

- *Typhoid in Those Vaccinated Against Typhic Infections. M. Monnier.—p. 301.

Typhoid After Vaccination.—On the basis of more than twelve years' experience with vaccination against typhoid and paratyphoid in a medical mission in Syria, Monnier states that anybody who is vaccinated with a vaccine containing eberthian strains has a good chance of remaining free from typhic infections, provided this vaccination is renewed every year. Unfortunately, there are rare cases of failure which might bring a valuable treatment into disrepute. The author observed typhoid in vaccinated persons but never a fatal case. The cause for the failure may be that the vaccination was repeated only at intervals of two, three or even five years; or, if repeated annually, the person may have been debilitated by amebic dysentery, malaria or other infection or he may have consumed heavily polluted water. The author gives a detailed clinical history of a patient who contracted typhoid after vaccination and says that he observed three other mild cases in patients who had become infected in regions where there were epidemics. On the basis of these observations, the author says that the onset of typhic infections in the vaccinated is identical with that in the nonvaccinated but that there is nevertheless a reduction in gravity and in duration. The recovery is rapid and the change in the general condition is slight.

Spasm of Esophagus from Cervical Hypertrophic Spondylitis Deformans. G. Pescatori.—p. 530.

Intravenous Injection of Epinephrine.—Negri and Terzi studied the effects of an intravenous injection of 0.02 mg. of epinephrine on the gastric secretion and on some substances in the blood of twenty-five adults. The study was carried out by determinations of the chemistry of the gastric juice and of the sugar and the substances in the blood which have diastasic and antitryptic properties. The tests were made in the course of the histamine test alone and combined with epinephrine. The authors conclude that the secretion of free hydrochloric acid during stimulation by histamine is modified by an intravenous injection of a small dose of epinephrine in persons who have a normal or increased secretion of the acid. In the majority of cases of this type the secretion of hydrochloric acid which is induced by histamine stimulation is inhibited by epinephrine and in a few cases it is increased. The secretion of free hydrochloric acid is not modified by epinephrine in persons who have achlorhydria or hypochlorhydria. The secretion of combined hydrochloric acid, the organic acids of fermentation and the peptic ferments of the gastric juice, as well as the amount of substances which cause diastasis and antitryptic properties to the blood, do not change in the course of the histamine test when used alone or in combination with epinephrine. There is a slight lowering of glycemia in the course of the histamine test, whereas there is a moderate transient hyperglycemia early in the course of the combined histamine and epinephrine test. The authors believe that the results of the studies show a relation between contraction of the spleen and the secretion of hydrochloric acid by the stomach. A normal output of splenic blood regulates the secretion of hydrochloric acid, whereas a diminished output results in the production of hypochlorhydria or achlorhydria. The authors' statement seems to be supported by the fact that the gastric chemism is disturbed in all cases of splenomegaly from defective contraction of the structure and that this form of splenomegaly plays an important part in the pathogenesis of gastric and gastroduodenal diseases with disorders of the gastric secretion.

Policlinico, Rome

Dextrose in Cerebrospinal Fluid During Shock by Insulin Treatment in Schizophrenia. M. Fischer.—p. 851.
Torsion of Gallbladder. E. Giupponi.—p. 852.

Ucko's Reaction in Pulmonary Tuberculosis.—Rubino says that opinions in the literature on the value of Ucko's test for the functioning of the liver are conflicting. He followed the behavior of the reaction in 200 patients who were suffering from pulmonary tuberculosis. He found that the test gives strongly positive results in 40 per cent of the cases, slightly positive results in 30 per cent and negative results in 30 per cent. Strongly positive reactions correspond to grave forms of tuberculosis as well as those of long duration and when the patients are in poor nutritional condition. Slightly positive and negative results correspond respectively to chronic and benign forms and to tuberculosis recently developed or during recovery of the patients who are in satisfactory nutritional condition. The sedimentation speed parallels the results of Ucko's test. The author made a comparison of the results of Ucko's test with those of the tolerance test of aminoacetic acid, which are ascertained by the curves of amino acids in the blood before and fifteen, thirty and sixty minutes after the intravenous injection of 1.2 Gm. of aminoacetic acid.

The results of the tests parallel each other only in 50 per cent of the cases. The author concludes that Ucko's test is of value in the diagnosis of pulmonary tuberculosis and in estimating its intensity but that it has no value for the functioning of the liver.

Magnesium Sulfate in Whooping Cough.—Soto Pradera calls attention to the value of magnesium sulfate as a symptomatic treatment of whooping cough. He gave daily intramuscular injections of a 10 per cent solution of magnesium sulfate to forty patients (thirty-eight infants and children and two adults). The dose varied from 0.25 to 1.1 cc. per kilogram of body weight until from fifteen to twenty injections had been given, according to the stage of the disease. The patients' urine was normal before, during and after the treatment. The crisis of the blood did not change. There was a decrease in coughing and vomiting early in the course of the treatment in thirty cases, with consequent clinical control of the disease after about fifteen injections. The treatment failed in ten cases. According to the author the treatment has an antispasmodic and sedative effect, by which the evolution and duration of whooping cough are favorably modified. The results were better than those he obtained in a group of 107 cases which were managed by the administration of common symptomatic treatments (antipyrine, belladonna, sodium bicarbonate and ether by rectum). Chronic nephritis contraindicates the treatment. Satisfactory results have been previously reported in Argentina. The author advises the preparation of a 50 per cent solution of magnesium sulfate instead of the 10 per cent solution which he used and to give the injections in doses of 0.2 cc. per kilogram of body weight. The dose is well tolerated and the volume of the injection is smaller than that used in more dilute solutions and causes neither pain nor local inflammatory reaction.

Puerperal Sepsis Caused by Gas Bacillus.—Tscherner asserts that the puerperal sepsis caused by the gas bacillus takes a special position among the various forms of puerperal sepsis. That this form has been given little attention in the gynecologic literature he ascribes to the comparative rarity and to the fact that it is often not correctly identified; this applies especially to patients who survive the acute stage and later succumb to the renal changes. The author surveys the cases of puerperal gas bacillus sepsis that were observed at the women's clinic in Graz in the course of the last five years. He differentiates three groups and describes and discusses cases of each group. The first group includes women who die within a short time as the result of acute symptoms. The author ascribes this rapid course, on the one hand, to a severe intoxication of the organism by the protein products resulting from the breakdown of tissues, by the gas bacillus, on the other hand, to the impairment of the blood and the resulting reduction in oxygenation. The second group includes those women who survive the acute symptoms but in whom, after a temporary improvement, signs of severe uremia develop, to which they finally succumb. The cause of the severe functional disturbance of the kidney, which may lead to complete anuria, is generally an interstitial nephritis, and in addition to this there often exists a toxic impairment of the epithelium of the uriniferous tubules and an obliteration of many tubules with masses of methemoglobin. In spite of slow regeneration of the tubular epithelium and in spite of an increase in the

quantity of urine, the uremic manifestations advance rapidly, probably because of the presence in the blood stream of large quantities of protein waste products derived from the breakdown of tissues and blood corpuscles, the impaired kidney being no longer able to eliminate them. In addition to these renal changes, the author observed a case with spotty necroses in the kidney which were the result of vascular impairments that occur in hyperergic conditions. The author explains the possible development of such a hyperergic state in puerperal women. The third group of women includes those who recover from the puerperal gas bacillus sepsis following treatment with gas edema. He describes three cases of this type but emphasizes that the administration of gas bacillus serum promises success only if it is given early and in large doses. The reported case histories indicate that the polyvalent antitoxic gas edema serum may be given intravenously in quantities of 40 or 50 cc., that intramuscular injections of the serum may be given simultaneously or that streptococcus and anaerobic serum may be given in combination with it. In view of the fact that the early recognition of the gas bacillus sepsis is of great importance for the treatment, the author stresses that whenever after a birth or abortion an icterus develops or the urine is scanty and reddish, gas bacillus sepsis should be thought of and a bacteriologic examination should be made on specimens of blood, urine and placental tissue.

Urinary Calculi.—Dege observed the patients with urinary calculi treated in the Jena Surgical Clinic during the last ten years and states that improvement in roentgenologic technic due to introduction of the various contrast mediums and excretory urography within recent years makes it possible to demonstrate the presence of most stones, even those which cast a faint shadow. He had noted certain similarities between precipitation of urinary calculi and immunologic precipitation reactions. What is of importance is that the disturbance of the colloidal state necessary to bring about the original precipitation of a calculus in the urine need be of but short duration. This disturbance may no longer be demonstrable at the time of the passage of the stone. The primary disturbance plays no part in the growth of the stone. The author therefore draws a sharp line between the precipitation of a calculus and its growth. Precipitation of a calculus is the result of an important though transitory alteration in the general reactivity of the organism. It is not known just how this alteration effects the urine of the renal pelvis. It is possible that the influences originate in the circulation, perhaps as a disturbance in the peripheral blood vessels. The demonstrable relationships to the immunologic status of the body and to the vitamin economy suggest that precipitation of calculi is an expression of a disturbance in a profound and primitive body function. The cause of this disturbance is obscure in most cases or is incompletely revealed. The growth of the calculi is favored by the existence of secondary lesions. These may be exogenic in character, such as geographic peculiarities or type of nourishment; local, such as infection of the urinary passages, or anatomic changes; or they may be endogenous in character, owing to the alterations in the internal secretions or to heredity. The treatment has for its object the removal of the stone and the correction of the conditions favoring its growth.

Exophthalmic Goiter and Thyrotoxicoses.—Between 1921 and 1931, Breitner had operated on ninety-six patients presenting thyrotoxicosis and sixty-one presenting exophthalmic goiter. Of fifty patients whom he attempted to follow up, twenty-two gave reliable answers. He observed that complete development of the clinical picture coincides with enlargement of the thyroid and that operation in these cases results in a complete and lasting cure. The term "Morbus Basedow" is purely a clinical one. It may be further supported by the

evidence of a characteristic Basedow thyroid, the only contradictory evidence against which is the occasional finding in young persons of microscopic alterations characteristic of a genuine Basedow thyroid in the absence of all clinical manifestations of the disease. There are likewise occasional cases presenting clinical signs of exophthalmic disease without microscopic alterations in the thyroid characteristic of the disease. One must assume in such cases a "basedowification" of a colloid goiter or the development of a toxic adenoma, or some other functional change in a person with an exophthalmic constitution. The author concludes that the microscopic picture alone does not establish the diagnosis. Neither does it alter the clinical diagnosis. The thyroid in a case of acute exophthalmic goiter caused by a psychic upset will not show a typical microscopic picture of a genuine exophthalmic goiter. The gland here is in a state of increased functional activity. The psychic treatment has its place in the beginning. However, when the gland itself becomes a factor in the disease, the best results are obtained only by an attack on it. One must assume an exophthalmic constitution for the genuine cases of exophthalmic goiter. The causative factor may be a psychic insult or a disturbance in the endocrine balance (puberty, menopause, pregnancy). The purely functional origin of alteration leads in the course of the disease to morphologic alterations within the thyroid. The thyrotoxic state may be temporarily favorably modified by exhibition of iodine and thus reduce the hazards of the operative intervention. The effect of iodine therapy is most pronounced in the genuine cases of exophthalmic goiter. That is not the case in toxic adenoma, in which the iodine balance is entirely different from that in the exophthalmic goiter. The effect of iodine therapy in cases of septic origin designated by E. P. Sloan as "anaphylactic type" has not been worked out. In all the types, however, operative reduction of the size of the thyroid to the permissible minimum is the therapy of choice. The author finds that separate extracapsular ligation of all the four arteries of the thyroid does not enhance the therapeutic result.

Hydrochloric Acid-Collargol Reaction in Cerebrospinal Fluid.—Riebeling says that the reaction described by him differs in principle from all former reaction in that it protects a colloid against a precipitating acid by means of cerebrospinal fluid in different dilutions. His reaction requires a freshly prepared five hundredth normal hydrochloric acid, made from tenth normal hydrochloric acid, and a solution of collargol (a preparation consisting of colloidal silver and silver oxide), which is prepared freshly from a 1:1,000 stock solution. Of a series of carefully cleansed tubes, of the type that are used for Wassermann tests, the first one contains 0.5 cc., the second 0.8 cc., the third 0.9 cc., the fourth 1.4 cc. and the fifth 1.9 cc. of five hundredth normal hydrochloric acid. Then are added 0.5, 0.2, 0.1, 0.1 and 0.1 cc. of cerebrospinal fluid. From the fourth tube, after thorough mixing, 0.5 cc. is withdrawn; from the fifth tube 1 cc. is taken and pipetted into the sixth tube; 1 cc. is pipetted into the seventh and so on to the twelfth tube. Thus the tubes contain the following dilutions of cerebrospinal fluid: 1:2, 1:5, 1:10, 1:15, 1:20, 1:40, 1:80, 1:160 to 1:2,560. To each of these dilutions is added 1 cc. of the collargol solution. Then the tubes are shaken by hand and are left standing for at least six hours. It is best to take the final reading the following morning. The author says that the method is simple, economical and easy to read. The difference between the positive and negative reaction is quite clear. Discussing the evaluation of the reaction the author says that this is easy only if the test is made together with one of the more customary reactions, usually the mastix or the colloidal gold chloride test. With the usual colloid reactions a differentiation between paralysis and cerebral syphilis

is not always possible and a cerebrospinal fluid from a patient with tumor may simulate a reaction for paralysis; however, in the hydrochloric acid-collargol reaction noticeable differences can be seen. Moreover, the latter reaction shows greater differences in the cerebrospinal fluids from cases of meningitis and of syphilis. The mastic and colloidal gold reactions do not always do this. Thus the described reaction is suited especially for these cases. It is of value also in cases in which there is a slight increase in protein, in which the mastic and colloidal gold tests generally fail.

Fatty Degeneration of Cardiac Muscle.—Hitzenger says that the fatty degeneration of the cardiac muscle is clinically designated as "tigering." In reviewing the literature he shows that qualitative and quantitative changes in the blood are the chief factors in the development of tigering. It has been known to develop in a rather severe form in deficient hemopoiesis, especially in pernicious anemia. It is observed also in infectious diseases, such as diphtheria, scarlet fever and sepsis; in certain intoxications, in case of impairment of the coronary arteries and in pericarditic exudates that exert pressure. Then it is found as the final stage of hypertrophy of the cardiac muscle in valvular lesions, chronic disorders of the kidneys, emphysema, kyphoscoliosis and so on. In investigations on the influence of oxygen deficiency on organic functions, the author noticed tigering of the cardiac muscle in a case of symptomatic polycythemia in pulmonary emphysema. Later he observed four other cases of this type. In view of the fact that tigering of the cardiac muscle is usually ascribed to anemia, this observation at first surprised the author and so he investigated the problem further. He found that fatty degeneration of the cardiac muscle is the result of a deficient oxygenization of the blood. It develops in cases of polycythemia, when a hypoxemia of the arterial blood, resulting from an insufficiency of the respiratory organs, exists simultaneously. The tigering does not involve the entire heart uniformly but affects some parts more severely than others, in spite of the fact that the injurious factor acts on the entire heart. The most frequent localization of the tigering seems to be the left, large papillaris muscle. In one report on the distribution of the fatty degeneration, the chief localizations were mentioned in the following order: the cardiac stimulus conduction system, the left large papillaris muscle, the left and right cardiac walls, the right large papillaris muscle. It appears that those parts of the heart are most severely involved which functionally are most active. This seems to indicate that during hypoxemia these parts already receive an inadequate supply of oxygen, when for the less active parts the oxygen supply is still adequate. The simultaneous existence of diseases of the coronary arteries seems to promote fatty degeneration.

Pulsation of Jugular Vein in Ascites.—Lauda says that, when in cases of severe ascites a pulsation of the jugular vein was synchronous with the apical impulse of the heart, it was often regarded as a justification for the diagnosis of tricuspidal insufficiency. However, a more exact examination revealed the incorrectness of this assumption. The observed positive venous pulse was not a regurgitating one for in response to digital compression of the distal section of the vein either the jugular vein became empty or the venous pulse lessened in the almost empty vein. The most peculiar aspect of the pulse was that it changed with the position of the patient and that in certain postures it disappeared entirely. The topographic relation of the aorta to the upper vena cava seemed a possible explanation of the transmitted pulse. The aorta, because of its nearness to the vena cava, in case of elevation of the diaphragm and of the involved turning of the heart, is pushed close to the vena cava, so that the ascending part of the aorta is pressed into the vena

cava and the aortic pulse is transmitted to the blood in the vena cava superior and also in the jugular vein. When the positional relation of the aorta to the vena cava becomes less close as the result of a postural change in the patient, the jugular pulsation is lessened or disappears completely. It was found that the phenomenon occurs chiefly in cases of ascites in which the heart is of normal size; that is, in cirrhosis. In cardiac insufficiency with ascites and diaphragmatic elevation, on the other hand, it is either absent or of a mild degree. The author thinks that this might be due to the fact that an enlarged heart is not so prone to change its position. Moreover, it appears that a slight stasis of the jugular vein or of the vena cava favors the development of the phenomenon, whereas the excessive filling of the venous circulation in case of cardiac stasis inhibits the phenomenon.

Form and Function of Feet of Mountain Nomads in Anatolia. S. Irmak.—p. 396.

Chondrodysplasia.—Gäde directs attention to the fact that there is much confusion in the terminology of Ollier's disease. He says that the term chondromatosis is employed rarely. In the romance literature the term dyschondroplasia is in use. In the English literature the term chondrodysplasia is generally applied to the disease that was described by Ollier. In the German literature the term "Ollier's growth disturbance" has been in use and has been identified with the unilateral type of chondrodysplasia. As such it has been strictly differentiated from the bilateral form of the same disease. The author shows that this differentiation is not justified. Before giving his opinion about the terminology he reports five cases. The first one was a bilateral, multiple chondrodysplasia of the skeleton, the second one a multiple chondrodysplasia of the left hand, the third one a multiple chondrodysplasia of both hands and of the left foot, the fourth one a multiple chondrodysplasia of the right hand and the fifth one a chondrodysplasia of the fourth finger of the left hand. Surgical measures, such as supracondylar osteotomy, removal of chondromatous masses and implantation of bone splints produced favorable results. In order to clarify the problem of terminology of Ollier's disease, the author reviewed and compared ninety cases of multiple chondrodysplasia from the literature. He demonstrates that there is no unilateral type of chondrodysplasia, which in the German literature is identified with "Ollier's growth disturbance," but that there is only a more or less disseminated chondrodysplasia. The author says further that, although chondrodysplasia has been regarded as a hereditary disorder, there is no justification for this. The author found likewise the predominance of chondrodysplasia in the male sex not as great as had been stated by some authors. In order to throw light on the etiology, interferometric measurements were made on the blood in three of the author's cases. The results indicate that certain hormones might be regarded as having a causal role but as yet these observations should be estimated with great reserve. The prognosis of the disorder as regards malignant degeneration is favorable. The treatment should be surgical if possible; the chondromatous masses should be removed in order to avoid the development of deformities and spontaneous fractures. If deformities have already developed, the treatment should be partly a conservative-orthopedic one and partly an operative-correcting one.

Congenital Dislocation of Hip Joint.—Nagura and Shirahama made roentgenologic studies in ten cases in which congenital dislocation of the hip joint healed spontaneously. They observed spontaneous cure on both sides in two cases of bilateral dislocation and on one side in eight cases of bilateral dislocation; that is, twelve joints were cured spontaneously. The ten cases were found among a material of 128 cases. The authors conclude from the observations on this material that spontaneous cure of congenital dislocation of the hip joint occurs more often than has been assumed heretofore.

Therapy of Thrombopenic Purpura by Kephriine Hydrochloride.—Fleischhacker says that since a report by Klima about the favorable effects of kephrine hydrochloride in patients with thrombopenia, he used this preparation in a number of cases. He admits that in the acute, particularly the anaphylactic, form the estimation of the efficacy of kephrine hydrochloride is difficult, because in such cases the hemorrhages usually stop when the medicament against which the patient is hypersensitive is discontinued. More convincing are the results that are obtained in the chronic essential thrombopenias. In some of these the thrombocytes are reduced; there is a positive Rumpel-Leede stasis phenomenon and the slightest injuries cause extensive hematomas. These cases, as a rule, responded rapidly to treatment with kephrine hydrochloride. The hemorrhagic tendency could usually be arrested and the appearance of new hemorrhages stopped after one or two days of treatment. The thrombocytes usually increased. In some of the cases, normal figures could be obtained during the time of intensive treatment. The quantity of kephrine hydrochloride which is necessary to arrest the hemorrhages differs in the individual cases. As a rule the oral administration is sufficient, but during the acute stage it can be supported by intramuscular injection. When a certain degree of coagulability had been reached in chronic cases, the author usually discontinued the treatment. When this was done the thrombocytes often decreased again and hemorrhages recurred, but renewal of the treatment usually reestablished normal conditions in a comparatively short time. In the chronic cases, in which the thrombocyte values are constantly low, it will have to be decided whether continuous medication with kephrine hydrochloride will be sufficient or whether splenectomy will be necessary. In this connection the author points out that, even after splenectomy, recurrences have been known and that splenectomy involves a comparatively high mortality. In cases in which thrombopenia and hemorrhages recurred several years after splenectomy and in which all measures failed, kephrine hydrochloride proved effective. Moreover, the administration of kephrine hydrochloride may be valuable in preparing the patient for a splenectomy. In two cases of hemorrhagic diathesis in which thrombopenia developed as the result of an acute myeloblastosis, however, medication with kephrine hydrochloride failed completely.

 Errors in Induction and Maintenance of Artificial Pneumothorax. A. S. Furman.—p. 55.

Early Artificial Pneumothorax.—Torkanovskiy reports his observations on the changes produced in the normal lungs by artificial pneumothorax. He had subjected fifteen patients with epilepsy to artificial pneumothorax with the view of diminishing the number of attacks. The patients were first studied as to the circumference of the chest, the height, weight, spirometry, pulse, respirations, blood pressure, roentgenograms, p_{O_2} of the blood, alveolar tension, basal metabolism, potassium and calcium blood content, erythrocytes, blood albumins, acid-base index of the urine and blood gases. Gradual repeated insufflations, begun on the left side and extended to the right side, were carried out until 1,000 cc. of air was introduced into each pleural cavity. There were no complications of any

kind. Subjective complaints of difficulty in breathing in the course of the first day occurred only in cases in which 1,000 cc. of air was introduced into each pleural sac in one sitting. A complete collapse of the left lung, persisting for from two to three weeks, was obtained only after repeated insufflations of 1,000 cc. of air. The author was not able to obtain a total collapse of the right lung in any case. The alterations in the pulse, respirations and blood pressure following the introduction of pneumothorax after the first as well as after repeated insufflations were so insignificant as to suggest that pneumothorax causes no alterations in a normal lung. The acid-base metabolism remained uninfluenced. The erythrocyte count and hemoglobin remained about the same. There was no exudation into the pleural sac in any of the cases. The alterations noted were those of loss of weight and the diminution in the circumference of the chest of from 1 to 4 cm. The author was not able to confirm the original hypothesis underlying the pneumothorax therapy of epilepsy; namely, the shift from alkalosis to acidosis. He suggests that the beneficial effect on epilepsy may be due to the action of the inflated air on the sympathetic and parasympathetic nerve fibers running in the pleural leaves. He concludes that the fewer pathologic alterations in the lung, the safer the induction of pneumothorax. He therefore takes exception to the widely adopted notion that one must demonstrate a cavity and tubercle bacilli before resorting to the collapse therapy and suggests that the method be applied in earlier cases—those with positive roentgenograms and signs of progression.

 Ocular Complications in Weil's Disease. M. S. Koster.—p. 1577.

Atropine Therapy in Postencephalitic Parkinsonism.—Grewel describes five years' experiences with ambulatory atropine therapy in patients with postencephalitic parkinsonism. Observations on about thirty patients convinced him that the medication must be individualized, for whereas some patients may tolerate the oral administration of 10 or even 12 mg. of atropine sulfate three times daily, others may not be able to tolerate even much smaller doses. The author never increased the dosage to more than 35 mg. a day, because such large doses involve the danger of complications. As a rule, the daily dose does not exceed 7 or 9 mg. Moreover, even in the individual patient the tolerance for atropine sulfate may change in the course of time. The optimal dose often may become somewhat reduced in the course of years so that it seems justified to inquire whether, in addition to the symptomatic effect, atropine sulfate may not also have a causal therapeutic influence. In some patients, who in the end felt comparatively well without medication and in whom only a certain stiffness remained, such a possibility may be considered. Sudden interruption of the medication involves danger, because of the symptoms of abstinence; however, the dangers of irregular medication are probably negligible. Discussing the symptoms that are favorably influenced by the atropine medication, the author mentions rigidity, amyostasia and other coordination disturbances. The reduction in tremor is often quite striking and this is a great encouragement for the patients. The visual cramps, the pulsation phenomena and the hypersalivation are likewise favorably influenced and the immobile facies disappears almost entirely. Speech disturbances, involuntary laughter, ties and spastic torticollis are hardly at all influenced. It is noteworthy that the psychotic symptoms often disappear under the influence of treatment with atropine. On the whole, the author found the effects of the atropine therapy satisfactory, but he is unable to share the great enthusiasm that at first prevailed, because, as is indicated by the persisting speech disturbances, the coordination is never completely restored. In giving his attention to the disorders that may result from continued atropine therapy, the author mentions paranoid and hallucinatory psychoses. In several of his patients a paranoid psychosis developed. He describes these cases and suggests that the cerebral damage and the chronic intoxication work together in the elicitation of this psychosis.

SUPPOSED ROLE OF THE ADRENALS IN HYPERTENSION

AN EXPERIMENTAL INVESTIGATION

J. M. ROGOFF, M.D., D.Sc.

AND

EMANUEL MARCUS, Ph.D.

CHICAGO

Our experiments constitute part of an investigation on the alleged relation of the adrenal medulla to certain diseases, particularly diabetes mellitus and hypertension. The supposition of such a relation is a basis for the clinical practice of surgical intervention at the adrenals or roentgen irradiation of the adrenal region as a therapeutic measure. Therefore it is important to determine if possible whether this alleged relationship can be supported by unequivocal experimental evidence.

The prevailing concept that increased epinephrine secretion from the adrenal glands has an important role in the etiology and the pathology of hypertension rests largely on the experimental basis for the theory of an "emergency" function of the adrenals. In a discussion of their experiments on epinephrine secretion during emotional excitement, on which the well known emergency theory rests, Cannon and de la Paz¹ stated:

Injected epinephrine is capable of inducing an atheromatous condition of the arterial wall in rabbits, especially in elderly individuals, and is also capable of evoking hyperglycemia with glycosuria. As Ascher has shown, by prolonged stimulation of the splanchnic nerves, prolonged secretion of epinephrine with maintained high blood pressure can be produced. In the light of the results here reported the temptation is strong to suggest that some phases of these pathologic states are associated with the strenuous and exciting character of modern life acting through the adrenal glands.

They² further suggested the possibility that "some of the adrenal secretion set free by nervous stimulation returns to the glands in the blood stream, and, within limits, stimulates them to further activity" and in this manner produces an "autogenous continuance of adrenal secretion."

If this occurs, it is conceivable that it might lead to continued liberation of epinephrine in sufficient

amounts to cause a persistent elevation of blood pressure. However, it seems paradoxical that a physiologic mechanism presumably evolved to serve the organism in emergencies should at the same time constitute a serious potential menace. For, if the aforementioned suggestions, made by Cannon and de la Paz, are carried to a logical conclusion, emotional excitement should initiate a cycle of continuous secretion of epinephrine and inevitably lead to development of diabetes and hypertension. Unless it is assumed that the adrenals are soon fatigued, the question arises how such a cycle would be terminated. It has been demonstrated that the peripheral mechanism for secretion of epinephrine is not readily fatigued.³ Repeated splanchnic stimulation at short intervals over many hours was performed without causing adrenal fatigue. When the experiment was terminated the adrenal was still capable of responding further to splanchnic stimulation. Not only was the output of epinephrine increased by the repeated stimulation but its production by the gland was augmented.

The experiments of Dragstedt, Prohaska and Harms⁴ on experimental hypertension demonstrate that continuous intravenous injection of epinephrine in dogs in amounts corresponding to from five to fifteen times the average normal quantity secreted from the adrenals, as determined by Stewart and Rogoff,⁵ cannot be continued for longer than a few days without serious or fatal consequence. Similar results, occurring within a few hours, were observed by us when doses three or more times as large as those employed by Dragstedt and his co-workers were administered. Our experiments support the conclusion, drawn by Dragstedt, Prohaska and Harms, that "it seems very probable that a degree of hyperadrenalinemia sufficient to produce hypertension would soon cause the death of the individual from other systemic effects of the hormone" and that "for this reason it does not seem probable that persistent hypertension in man will be found to be due to hyperadrenalinemia."

If epinephrine secretion is in any way related to production of hypertension, it would seem probable that other factors might render the circulatory or vasomotor apparatus hypersensitive to epinephrine, which could then induce hypertension in the amounts ordinarily secreted. We are attempting to study this possibility in another investigation. The present report includes

quantitative studies on the output of epinephrine from the adrenals and on its disappearance from the systemic circulation after intravenous injection of various amounts.

QUANTITATIVE EXPERIMENTS ON THE RATE OF
SECRETION OF EPINEPHRINE AFTER INTRA-
VENOUS ADMINISTRATION OF
EPINEPHRINE

We made quantitative measurements with eleven dogs of the output of epinephrine from the adrenals to determine whether intravenous injection of epinephrine is capable of modifying the rate of secretion. Quantities ranging from ten to 500 times the average amount of epinephrine ordinarily secreted by the adrenals per minute were introduced. The epinephrine concentration in the blood and the rate of secretion were determined by the method of Stewart and Rogoff. In some of the experiments the results were confirmed by the method recently described by Rogoff,⁶ in which sensitized eye reactions in cats are employed.

In some of the experiments the epinephrine was administered at a constant rate; in others it was given in a single injection, to simulate the "outburst" from the adrenals that is alleged to occur during emotional excitement. The smallest dose employed, i. e., 0.002 mg. per kilogram of body weight a minute, caused an elevation of blood pressure during the injection in anesthetized dogs; striking reactions in the blood pressure were produced by the larger doses.

For constant injection we employed an apparatus devised by one of us (J. M. R.). The essential construction of the device includes a constant speed motor which drives a nugged disk by a hard rubber friction drive; the disk operates a pinion and gear reduction to a screw which is kept in constant motion, propelling forward the piston of one, two or three syringes. When syringes with a capacity of 50 cc. are used, adjustment can be made so that any quantity between 0.7 cc. and 7.5 cc. a minute can be delivered at a constant rate of flow against any pressure that might be met in the blood vessel. Further alteration of the range of quantities delivered can be accomplished by employing syringes of different capacity.

The results of our experiments on the rate of liberation of epinephrine from the adrenal glands under the influence of intravenous administration of epinephrine are illustrated in the following condensed protocols:

EXPERIMENT 1.—In a male dog weighing 14.1 Kg. a cava pocket was prepared with the aid of urethane anesthesia. When the first specimen of adrenal blood was obtained, the blood flow was 22 Gm. a minute and the blood pressure 110 mm. of mercury. Constant intravenous injection of 0.028 mg. of epinephrine a minute was performed for three minutes (corresponding to ten times the normal average rate of adrenal secretion); the maximum blood pressure was 118 mm. The second specimen of adrenal blood was obtained immediately after the injection; the blood flow was 13.9 Gm. a minute and the blood pressure from 108 mm. to 94 mm. The third specimen of adrenal blood was obtained during electrical stimulation of the branchial nerve. Quantitative assay was unsatisfactory; differences between an epinephrine concentration of 1:5,000,000 and one of 1:10,000,000 were not detectable with the test object. All three specimens were found to have a concentration within this range, indicating qualitatively a normal output and no significant influence exerted by injected epinephrine or by sensory stimulation.

EXPERIMENT 2.—In a dog weighing 10.25 Kg. a cava pocket was prepared with the aid of pentobarbital sodium anesthesia. When the first specimen of adrenal blood was obtained the

blood flow was 14.6 Gm. a minute. Constant intravenous injection of 0.04 mg. of epinephrine a minute was performed for one minute (corresponding to twenty times the normal average rate of adrenal secretion). The second specimen of adrenal blood was obtained immediately after the injection; the blood flow was 10.5 Gm. a minute. Twenty-five minutes later, constant injection of 0.04 mg. of epinephrine for one minute was repeated, and immediately thereafter the third specimen of adrenal blood was obtained. The blood flow was 8.25 Gm. a minute. The first specimen was assayed at an epinephrine concentration 1:6,500,000, corresponding to an output of 0.00224 mg. a minute for the dog, or 0.00022 mg. per kilogram a minute. The second specimen was assayed at a concentration of 1:5,000,000 and the third at a concentration of 1:4,000,000, both concentrations corresponding to an output of 0.0021 mg. a minute for the dog, or 0.0002 mg. per kilogram a minute.

EXPERIMENT 3.—In a dog weighing 8.75 Kg. a cava pocket was prepared with the aid of pentobarbital sodium anesthesia. When the first specimen of adrenal blood was obtained, the blood flow was 10.7 Gm. a minute and the blood pressure 132 mm. of mercury. Constant intravenous injection of 0.036 mg. of epinephrine was performed for one minute (corresponding to twenty times the normal average rate of adrenal secretion). The second specimen of adrenal blood was collected during one minute, beginning thirty seconds before the end of the injection; the blood flow was 9.5 Gm. a minute and the maximum blood pressure 156 mm. The first specimen was assayed at an epinephrine concentration of approximately 1:50,000,000, corresponding to an output of 0.000214 mg. a minute for the dog, or 0.000024 mg. per kilogram a minute. The second specimen was assayed at a concentration of approximately 1:20,000,000, corresponding to an output of 0.00047 mg. a minute for the dog, or 0.000053 mg. per kilogram a minute.

EXPERIMENT 4.—In a female dog weighing 7 Kg. a cava pocket was prepared with the aid of pentobarbital sodium anesthesia. The blood pressure was 112 mm. of mercury. Constant intravenous injection of 0.07 mg. of epinephrine a minute was performed (corresponding to fifty times the normal average rate of adrenal secretion). The first specimen of adrenal blood was obtained ten minutes after the beginning of the injection; the blood flow was 6.2 Gm. a minute and the maximum blood pressure 182 mm. The second specimen of adrenal blood was obtained twenty minutes after the beginning of the injection; the blood flow was 9.6 Gm. a minute and the blood pressure 142 mm. The first specimen was assayed at an epinephrine concentration of 1:4,000,000, corresponding to an output of 0.00155 mg. a minute for the dog, or 0.00022 mg. per kilogram a minute. The second of the specimens was assayed at a concentration of 1:5,000,000, corresponding to an output of 0.00192 mg. a minute for the dog, or 0.00027 mg. per kilogram a minute.

EXPERIMENT 5.—In a female dog weighing 9.35 Kg. a cava pocket was prepared with the aid of urethane anesthesia. The blood pressure was 104 mm. of mercury. A constant intravenous injection of 0.187 mg. of epinephrine a minute was performed (corresponding to 100 times the normal average rate of adrenal secretion). A specimen of adrenal blood was obtained six minutes after the beginning of the injection; the blood flow was 13.98 Gm. a minute and the maximal blood pressure 170 mm. Simultaneously with the collection of the adrenal blood, a specimen of arterial blood was withdrawn from the abdominal aorta. The adrenal blood was assayed at an epinephrine concentration of 1:1,000,000, corresponding to an output of 0.0139 mg. a minute for the dog, or 0.00148 mg. per kilogram a minute. The epinephrine concentration in the arterial blood was determined to be slightly less than that in the adrenal blood.

EXPERIMENT 6.—In a female dog weighing 9.65 Kg. a cava pocket was prepared with the aid of urethane anesthesia. Constant intravenous injection of 0.386 mg. of epinephrine a minute was performed for two minutes (corresponding to 200 times the normal average rate of adrenal secretion). When a specimen of adrenal blood was obtained just after the injection, the blood flow was 12.3 Gm. a minute and the blood pressure from 210 to 170 mm. of mercury. A specimen of arterial blood was withdrawn from the abdominal aorta thirty seconds after the specimen of adrenal blood was obtained; the blood pressure was 129 mm. The adrenal specimen was assayed at an epinephrine con-

6. Rogoff, J. M.: A Sensitive Method for Quantitative Estimation of Epinephrine in Blood, *Proc. Soc. Exper. Biol. & Med.* 36:441 (May) 1937.

centration of 1:4,000,000, corresponding to an output of 0.003 mg. a minute for the dog, or 0.00031 mg. per kilogram a minute. The epinephrine concentration in the arterial blood was determined to be approximately 1:10,000,000.

EXPERIMENT 7.—In a female dog weighing 8.9 Kg. a cava pocket was prepared with the aid of urethane anesthesia. The blood pressure was 95 mm. of mercury. Constant intravenous injection of 0.54 mg. of epinephrine a minute was performed for two minutes (corresponding to 300 times the normal average rate of adrenal secretion). A specimen of adrenal blood was obtained during the ascent of the blood pressure, which reached a maximum of 205 mm.; the blood flow was 14 Gm. a minute. During the injection and simultaneously with the collection of the adrenal blood, a sample of arterial blood was withdrawn from the abdominal aorta. The blood pressure after the injection fell to 88 mm. The adrenal blood was assayed at an epinephrine concentration of 1:1,500,000, corresponding to an output of 0.00933 mg. a minute for the dog, or 0.00105 mg. per kilogram a minute. The epinephrine concentration in the arterial blood differed but little from that in the adrenal blood.

EXPERIMENT 8.—In a male dog weighing 9.5 Kg. a cava pocket was prepared with the aid of urethane anesthesia. When the first specimen of adrenal blood was obtained, the blood flow was 6.5 Gm. a minute and the blood pressure 68 mm. of mercury. Constant intravenous injection of 1 mg. of epinephrine a minute was performed for two minutes (corresponding to 500 times the normal average rate of adrenal secretion). The second specimen of adrenal blood was obtained within thirty seconds after the injection, while the blood pressure was still at the maximum height reached, 185 mm.; the blood flow was 15.5 Gm. a minute. The third specimen of adrenal blood was obtained five and one-half minutes after collection of the second; the blood flow was 2.33 Gm. a minute and the blood pressure 40 mm. The first specimen was assayed at an epinephrine concentration of 1:3,000,000, corresponding to an output of 0.0021 mg. a minute for the dog, or 0.00022 mg. per kilogram a minute. The second specimen was assayed at a concentration of 1:500,000, corresponding to an output of 0.031 mg. a minute for the dog, or 0.0032 mg. per kilogram a minute. The third specimen was assayed at a concentration of 1:5,000,000, corresponding to an output of 0.00047 mg. a minute for the dog, or 0.00005 mg. per kilogram a minute.

EXPERIMENT 9.—In a female dog weighing 8.5 Kg. a cava pocket was prepared with the aid of urethane anesthesia. When the first specimen of adrenal blood was obtained, the blood flow was 16.9 Gm. a minute and the blood pressure 80 mm. of mercury. Intravenous injection, a single dose of 0.5 mg. of epinephrine, was performed (corresponding to 300 times the normal average adrenal output a minute). The blood pressure rose to a maximum level of 188 mm. The second specimen of adrenal blood was obtained during the return of the blood pressure; the blood flow was 12.25 Gm. a minute and the blood pressure at the end of the collection 56 mm. The third specimen of adrenal blood was obtained fifteen minutes after the second; the blood flow was 13.2 Gm. a minute and the blood pressure 58 mm. The three specimens showed but little difference in epinephrine concentration; they were assayed at a concentration of 1:4,000,000, corresponding to outputs of 0.004 mg., 0.0031 mg. and 0.0033 mg. a minute for the dog, or 0.00048 mg., 0.00036 mg. and 0.00039 mg. per kilogram a minute for the first, second and third specimens, respectively.

EXPERIMENT 10.—In a male dog weighing 9.5 Kg. a cava pocket was prepared with the aid of urethane anesthesia. When the first specimen of adrenal blood was obtained the blood flow was 11.4 Gm. a minute and the blood pressure 88 mm. of mercury. Intravenous injection, a single dose of 0.8 mg. of epinephrine, was performed (corresponding to 450 times the normal average adrenal output per minute). The blood pressure rose to a maximum of 175 mm. The second specimen of adrenal blood was obtained during the period of elevated blood pressure; the blood flow was 16.6 Gm. a minute. The third specimen of adrenal blood was obtained seven minutes later; the blood flow was 7.1 Gm. a minute and the blood pressure 67 mm. The first specimen was assayed at an epinephrine concentration of 1:5,000,000, corresponding to an output of 0.00228 mg. a minute for the dog, or 0.00024 mg. per kilogram a minute. The second

specimen was assayed at a concentration of 1:3,000,000, corresponding to an output of 0.0055 mg. a minute for the dog, or 0.00057 mg. per kilogram a minute. The third specimen was assayed at a concentration of 1:4,000,000, corresponding to an output of 0.00177 mg. a minute for the dog, or 0.000186 mg. per kilogram a minute.

EXPERIMENT 11.—In a male dog weighing 10.25 Kg. a cava pocket was prepared with the aid of pentobarbital sodium anesthesia. When the first specimen of adrenal blood was obtained the blood flow was 9.65 Gm. a minute and the blood pressure 104 mm. of mercury. Intravenous injection, a single dose of 1 mg. of epinephrine, was performed (corresponding to 500 times the normal average adrenal output a minute). The blood pressure rose to a maximum level of 225 mm. The second specimen of adrenal blood was obtained during the ascent of the blood pressure; the blood flow was 10 Gm. a minute. Quantitative assay of the epinephrine concentration in the first specimen was not satisfactory; qualitatively, this specimen was much weaker than the second. The second specimen was assayed at an epinephrine concentration of 1:750,000, corresponding to an output of 0.0133 mg. a minute for the dog, or 0.0013 mg. per kilogram a minute.

The evidence derived from these experiments is against the probability of an autogenous continuance of adrenal secretion produced by circulating epinephrine. Constant intravenous administration of epinephrine, in amounts comparable to the rate of adrenal secretion under powerful stimulation, did not alter the output of epinephrine from the glands, although elevation of blood pressure occurred in every instance; nor was the epinephrine concentration in the blood of the adrenal vein different from that usually found in normal dogs under ordinary experimental conditions.

Increase in the rate of secretion of epinephrine up to twenty or thirty times the normal rate can be produced by electrical excitation of the splanchnic nerves⁷ or by the action of certain drugs.⁸ In dogs 1, 2, 3 and 4, quantities of epinephrine up to fifty times the normal average amount liberated by the adrenals were administered.

For some unknown reason the initial output of epinephrine in dog 3 was exceedingly low. Nevertheless, although the calculated output during the injection of epinephrine is double the initial output, the latter was not even increased to a level approaching the normal rate of liberation. It has been found that an increase can be accomplished by splanchnic stimulation under similar circumstances.⁹ It would seem that a low rate of secretion should be favorable for obtaining an increase, especially when the stimulus presumably would act on the peripheral secretory mechanism.

When the rate of blood flow through the adrenals is not diminished, an increase in the concentration of epinephrine indicates augmentation of the rate of liberation. In these experiments, however, the increased concentration of epinephrine in the blood of the adrenal vein may have been due chiefly, if not entirely, to the injected epinephrine in the circulation. Owing to the relatively high rate of blood flow through the adrenals, the blood of the adrenal vein is largely arterial and, to a certain extent, reflects the epinephrine concentration in the arterial blood; therefore, when large quantities of epinephrine are injected, the increased concentration may lead to an erroneous interpretation of increased

7. Stewart, G. N., and Rogoff, J. M.: Effect of Stimulation of Afferent Nerves upon the Rate of Liberation of Epinephrine from the Adrenals, *Am. J. Physiol.* **69**: 605 (Aug.) 1924.

rate of secretion by the adrenals. This possibility is demonstrated by the results obtained in the dogs receiving massive doses of epinephrine.

Thus, in dogs 5 and 7, specimens of blood from the adrenal vein were collected while large amounts of epinephrine were being introduced into the circulation; arterial blood, taken from the aorta, was obtained simultaneously with the collection of adrenal blood. The epinephrine concentration was practically the same in the arterial and in the adrenal blood, and the calculated output from the adrenals appeared higher than normal. In dog 6, however, adrenal blood taken after the injection of a large dose of epinephrine showed but little, if any, increase in output; arterial blood taken shortly thereafter showed an epinephrine concentration too low to modify significantly the calculated output from the adrenals.

Similar results were obtained in the animals (dogs 9, 10 and 11) to which large amounts of epinephrine were administered in single injections, to simulate an outburst from the adrenals. The apparent increase in the output of epinephrine was in every case due to the fact that there was a large amount of circulating epinephrine for a brief period after the injection, for only those specimens of adrenal blood which were collected during the period of pressor activity of the injected epinephrine showed a calculated increase in output from the adrenals.

Of course, although the epinephrine concentration in the arterial blood roughly paralleled that of the adrenal blood, it would be difficult to maintain that a small increase in output is not included in the calculated, apparent increase. However, if such an increase does occur it is brief, for as soon as the pressor effect of the injected epinephrine subsides it is no longer possible to demonstrate an apparent increase in output from the adrenals. Indeed, our experiments indicate the probability that immediately after the hemodynamic effects of the injected epinephrine there is a brief period of diminished output of epinephrine from the adrenals (dogs 8 and 10), the output returning to the original level within fifteen minutes (dog 9).

If epinephrine is capable of exerting an inhibitory action on the adrenal medulla, Elliott's¹⁰ observation that the store of epinephrine in the adrenal is diminished after injections of epinephrine might be explained by a possible inhibitory influence on the rate of production. At any rate, diminished store alone is not adequate evidence of increased liberation of epinephrine from the adrenals; at most it affords information on the balance between production and liberation.

QUANTITATIVE EXPERIMENTS ON THE DURATION OF EFFECTIVE CONCENTRATIONS OF EPINEPHRINE IN THE SYSTEMIC CIRCULATION

The brief hemodynamic effect of a single intravenous injection of epinephrine is well known. In view of the subject under investigation, we performed thirty-two quantitative experiments, on fifteen dogs, to determine whether some of the injected epinephrine might be retained in the blood longer than the period corresponding to its pressor action, especially when relatively large amounts are administered constantly over a long period.

Epinephrine was introduced intravenously in amounts equivalent to the increased quantities secreted from the adrenals under powerful stimulation.¹¹ From ten to

fifty times the average amount normally secreted by the adrenals was administered at a constant rate of injection. Systemic blood was obtained at intervals during and after the injections, which were continued for periods ranging from thirteen to ninety-four minutes, from anesthetized and nonanesthetized animals.

In most of these experiments we used the serum instead of defibrinated blood for determination of the epinephrine concentration. This is advantageous when the concentration is low, since it has been found that all the epinephrine in the blood is in the serum or the plasma.¹² Thus, a concentration too weak for detection in the blood often may be detected quantitatively in the serum, in which the concentration is approximately twice as great. Specimens of blood were obtained (a) from the left ventricle or the femoral artery, (b) simultaneously from the abdominal aorta and the vena cava, (c) simultaneously from the right ventricle and the femoral artery and (d) from both ventricles, from one to three minutes apart, the order of collection being reversed in different experiments.

We found that intravenously injected epinephrine disappears from the circulation so rapidly that it is rarely detectable in the blood beyond the period of its pressor action. These results, on dogs, confirm the unpublished results on cats, obtained earlier by Rogoff and Wasserman at Western Reserve University. In both dogs and cats, when single injections of amounts up to about ten or fifteen times the average normal output of the adrenals a minute have been given, epinephrine can no longer be detected in the systemic (arterial) circulation after one complete circuit of the blood. This is true also when such amounts are injected constantly over relatively long periods; as soon as the injection is stopped and the blood pressure returns to the original level, the epinephrine cannot be found in the blood with sensitive test objects. When a quantity equal to from twenty-five to fifty or more times the average normal output of the adrenals a minute is administered in a single injection, approximately one half or one fourth of the epinephrine may be detected in arterial blood obtained within one-half or one minute after the injection.

Rarely was an epinephrine reaction produced by the serum when blood was obtained two or more minutes after a single injection of epinephrine, although sensitive test objects were often available. When large amounts of epinephrine were injected at a constant rate for an hour or longer, a small reaction was occasionally observed for some minutes (in one instance up to twenty minutes) after the end of the injection. However, prolonged administration of such large doses is not well tolerated by the animals.

Our experiments demonstrate that epinephrine disappears rapidly from the systemic blood when it is introduced into the circulation in amounts equivalent to those liberated by the adrenals under strong stimulation. For example, epinephrine was injected intravenously at a constant rate of 0.038 mg. a minute in a dog weighing 12.8 Kg. Arterial blood obtained twenty-two minutes after the beginning of the injection contained an epinephrine concentration of approximately 1:200,000,000. A specimen obtained shortly after the end of the injection was assayed at an epinephrine concentration of less than 1:800,000,000. In twenty-two minutes 0.836 mg. of epinephrine entered the blood stream; if all of it

had been retained in the circulation there should have been an epinephrine concentration of nearly 1:1,000,000 in the arterial blood. Thus more than 99 per cent of the epinephrine disappeared from the blood in the systemic circulation during the injection.

Assay of specimens of blood collected simultaneously from the abdominal aorta and the vena cava during constant intravenous (external jugular vein) injection of epinephrine in amounts equal to from fifteen to thirty times the average normal quantity of adrenal secretion showed a loss of approximately half of the epinephrine from the arterial blood while it was passing to the venous side of the vascular system. A similar loss of epinephrine was observed in the blood coursing through the pulmonary circuit.

Unless it can be proved that there is an impairment in the capacity for removing epinephrine from the circulation in hypertension, it is highly improbable, in the light of these quantitative observations, that hypersecretion of epinephrine by the adrenals and presence of epinephrine in the systemic circulation in concentrations capable of producing a persistent elevation of blood pressure can be a cause of chronic hypertension. Such concentrations, if present, could be detected by our methods.

Reports in the literature alleging that epinephrine was detected in the systemic circulation in cases of various conditions may be said to have been based on improper use of methods or use of improper methods. Incredible concentrations have been reported; in some cases, simple arithmetical calculation would show the improbability, if not impossibility, of the existence of such epinephrine concentrations in the circulating blood. In 1931 Rogoff and Wasserman¹³ tested systemic blood from a small group of patients with hypertension (obtained through Dr. R. W. Scott at Cleveland City Hospital) and were unable to detect epinephrine. Stewart¹⁴ had previously reported similar negative results, using the same method.

A number of other investigators, working with satisfactory but less sensitive methods, failed to detect epinephrine in the systemic blood after the pressor effects of large doses had subsided. The mechanism whereby the epinephrine disappears from the blood is unknown; probabilities are oxidation, fixation or utilization by tissues on which it acts, elimination or a combination of these. Excretion by the kidneys has been suggested, but the alleged detection of epinephrine in urine is based on work with unreliable methods. Jackson¹⁵ found that the duration of the pressor effects of epinephrine is not altered by ligation of the renal blood vessels.

We performed experiments in which acute hypertension was produced by renal ischemia following firm application of Goldblatt's clamps and others in which it was produced by ligation of the renal arteries. Some of the dogs acquired acute uremia, especially those in which the renal arteries were ligated. In some but little hypertension developed, while in others there was considerable elevation of blood pressure. In none of the animals was the rate of secretion of epinephrine from the adrenals different from that ordinarily found in normal dogs. Goldblatt¹⁶ was able to produce chronic

hypertension by renal ischemia in dogs after excision of one adrenal and denervation of the other with mechanical destruction of its medulla. This type of hypertension, therefore, apparently is independent of the secretion of epinephrine from the adrenals.

COMMENT

Existing experimental and clinical evidence is inadequate to support the view that epinephrine secretion is an important factor in the etiology and pathology of chronic hypertension. With the possible exception of conditions arising from the presence of certain types of adrenal medullary neoplasms, the concept of hypersecretion of epinephrine as a cause of persistent elevation of the blood pressure is untenable. Our quantitative experiments contradict the suggestion that an "autogenous continuance" of secretion of epinephrine is possible.

The so-called emergency theory of adrenal function has furnished support to advocates of various ideas and practices in clinical medicine for a quarter of a century. The theory is attractive, but it has been contested severely on the ground that it is not based on unequivocal, quantitative, experimental premises. The present investigation adds to the evidence against the principles supported by this theory.

Serious consequences may arise from premature application of unproved theory to clinical practice. There is a growing tendency among clinicians to resort to surgical intervention at the adrenals or their nerves or to subject the adrenal region to roentgen irradiation in the treatment of hypertension. Damage to the adrenal blood vessels may lead to degeneration and atrophy of the indispensable adrenal cortex.¹⁷ It has been shown that adrenal operations for therapeutic purposes may lead to development of fatal Addison's disease.¹⁸

In some cases, irradiation of the hypophysis as well as of the adrenals is practiced. If it is assumed that an interrelated function between the hypophysis and the adrenal medulla is involved in such treatment, we may point out that hypophysectomy does not alter the rate of secretion of epinephrine from the adrenals.¹⁹ Page and Sweet²⁰ produced hypertension by renal ischemia in hypophysectomized dogs; when they performed hypophysectomy after producing hypertension the pressure declined. In 1935 one of us (J. M. R.) collaborated in a portion of the preliminary experiments by Dr. Harry Goldblatt on hypophysectomized dogs. It was found that hypophysectomy does not prevent development of hypertension due to renal ischemia. At any rate, we believe that the experimental basis for intervention at the hypophysis in the treatment of hypertension is even less substantial than intervention at the adrenals.

Our experiments lend no support to the possibility of an accumulation of epinephrine in the circulation in amounts capable of causing sustained elevation of blood pressure. The presence of such quantities of epinephrine in the circulation would produce effects, other

than hypertension, which could not be tolerated for more than a relatively short period. We have shown that even large amounts of epinephrine introduced into the circulation disappear from the systemic blood very rapidly. Furthermore, we have demonstrated that an increased concentration of epinephrine in the systemic circulation does not produce a detectable increase in epinephrine secretion from the adrenals. Accordingly, the premise on which rests the theory that hypersecretion of epinephrine is a cause of hypertension is not supported by quantitative measurements of the rate of secretion of epinephrine.

The clinical significance of this investigation is obvious. In our opinion, these experiments support the conclusion that intervention at the adrenals as a method for treating hypertension does not have the support of unequivocal experimental studies. The practice is not without considerable risk to the patient; therefore such heroic measures ought to be deprecated. We agree entirely with the final statement made in an editorial published recently in *THE JOURNAL*²¹ that "the therapeutic hazard in a disorder should not exceed the disease hazard."

INCIDENCE AND CAUSES OF CHRONIC DYSPEPSIA AT VARIOUS AGES

AN ANALYSIS OF 4,223 CASES

ANDREW B. RIVERS, M.D.
AND

ANTONIO E. MENDES FERREIRA, M.D.

Fellow in Surgery, the Mayo Foundation
ROCHESTER, MINN.

Turn on the radio, casually glance through advertisements in papers and periodicals or read the signs which are scattered everywhere along the highways, and it soon becomes evident how important symptoms of dyspepsia have become to the laity. All these advertising mediums give instructions on how to return to gastronomic happiness by easy and inexpensive means. In this paper we shall outline some of the more frequent causes of chronic dyspepsia and submit evidence pointing to the danger, particularly at certain ages, of the layman's attempting to cure himself by taking advertised therapeutic nostrums.

Physicians are in part responsible for this lamentable situation, because a diagnosis of "dyspepsia" is frequently made although, as is well known, this condition is not a disease but only a symptom. In the hope that certain symptoms are transitory and inconsequential, the physician sometimes advises easily available medications which have previously been found to be effective, and sometimes it turns out that serious disease has, because of the dilatory methods of diagnosis, been overlooked. Unfortunately, the severity of digestive disturbances is not necessarily an indication of the extent or gravity of the underlying cause, nor are pathologic processes giving rise to such symptoms limited to diseases of the stomach or duodenum or even to organs directly utilized and concerned in the process of digestion. A great variety of diseases may herald their approach or indicate their presence by causing disturbances in the smooth, rhythmic behavior of the processes of digestion.

MATERIAL FOR STUDY

To obtain the material for this study, 10,000 consecutive histories of patients aged 15 or older were scrutinized. In the first place we were interested in knowing how many of these patients complained of indigestion. If the complaints included symptoms of dyspepsia, the history was carefully analyzed in order to ascertain the causes of the complaint. A division of histories according to sex was then made and the causes of dyspepsia determined for each sex. We next proceeded to study the causes of dyspepsia in patients who presented themselves primarily because of this condition. Finally, because it is obvious that there must be some variation in the causes and the gravity of diseases responsible for dyspepsia at different ages, the histories were divided into three groups: the first for patients from 15 to 24 years of age, the second for patients from 25 to 39 and the third for patients of 40 and older.

INCIDENCE

A review of the histories in this series attests the fact that one of man's most frequent problems is related to his digestive unhappiness. More than 42 per cent of the patients included complained of dyspepsia, and about half of these presented themselves primarily because of dyspepsia. We were rather surprised to find that dyspepsia was slightly more common among men than among women. Of the 4,223 patients who volunteered the complaint of dyspepsia, 2,147 were males and 2,076 females. Of the male patients who included digestive disturbances among their complaints, 54 per cent came to the clinic primarily to seek aid for this complaint; only 41 per cent of the female patients with indigestion considered this their major ailment.

In chart 1 we have shown the incidence of dyspepsia at various ages for the 10,000 consecutive registrations included in this study. In clinic registrations we found proportionately less dyspepsia among persons less than 30 years of age. Between this age and 60 almost half of the total number of patients had some complaint of

Chart 1.—Incidence of dyspepsia in 10,000 consecutive cases. The black line represents the number of patients with a complaint of dyspepsia and the shaded blocks the total registrations for each age group for the same period.

digestive difficulties. After 60 the relative proportion of patients who complained of indigestion to total registrations for similar ages diminished somewhat. This does not mean, however, that the gravity of the complaint was proportionately less for older persons. In fact, as might be expected, the causes for the dyspepsia were of relatively graver significance for patients beyond the age of 40 than for younger patients.

From the Division of Medicine, the Mayo Clinic.

CLASSIFICATION

It would be confusing to enumerate separately all the heterogeneous maladies responsible for the dyspepsia in this series of 4,223 cases. We therefore intend to indicate the most common causes for the complaint in the various age groups and to list these and the less frequent causes according to the etiologic classification of dyspepsia suggested by Eusterman and Balfour.¹ They divided the causes of dyspepsia into four types: organic, reflex, systemic and functional. Under organic causes of dyspepsia we include diseases or anatomic anomalies involving the tissues of the stomach or duodenum. Among the reflex causes of dyspepsia we include diseases of the appendix, gallbladder, biliary ducts, pancreas or intestine and renal stone or other conditions which reflexly disturb the chemistry or mechanics of the stomach and duodenum. Among the dyspepsias of systemic origin we include those due to

Chart 2.—The twelve most common causes of dyspepsia in order of frequency.

disturbances of metabolism, toxemia, deficiency diseases or dysfunction of the organs of internal secretion. Functional dyspepsias will be assumed to include the disturbances in normal gastroduodenal activity not resulting from demonstrable disease elsewhere in the body. Of this type are the various gastric neuroses, constitutional inadequacies and habit dyspepsias and the various dyspeptic manifestations of chronic nervous exhaustion.

CAUSES OF DYSPEPSIA IN THE SERIES OF 4,223 CONSECUTIVE CASES

A classification of the twelve most common causes of indigestion in order of frequency will be found in chart 2. These twelve causes account for 74.6 per cent of the total number of cases. The remaining causes, a long heterogeneous list, when added to these twelve result in a total incidence as follows: systemic dyspepsia 37 per cent, functional dyspepsia 25 per cent, reflex dyspepsia 22 per cent and organic dyspepsia 14 per cent. In 2 per cent of the cases no diagnosis could be made. Included are all instances of dyspepsia, regardless of whether the condition was the primary or an associated complaint. In a general way the causes of the dyspepsia as indicated in chart 2 are not greatly at

variance with those reported by Dwyer and Blackford² and by Davis and Vanderhoof.³

In chart 3 we have shown the ten most frequent causes of dyspepsia for both males and females. For each sex functional causes remain the most frequent, peptic ulcer being next in importance for the males and cholecystic diseases assuming the same position for the females. Cancer of the stomach was relatively

Chart 3.—The ten most frequent causes of dyspepsia according to sex.

important among the males. It is interesting to note that dyspepsia of organic origin was more than three times as frequent in the males as in the females.

Dyspepsia as a Primary Complaint.—The cases thus far considered have included all those of dyspepsia regardless of whether this complaint was considered as of primary or as of secondary importance. Many of the patients came to the clinic for other reasons and during the course of examination mentioned the fact that they also suffered from digestive disturbances. We thought that more accurate information regarding the important causes of dyspepsia could be obtained if we considered separately a group of patients who came to the clinic primarily because of dyspepsia. In chart

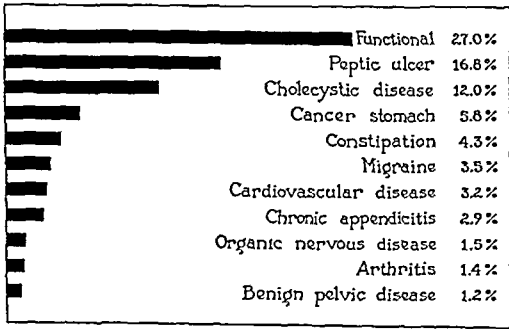

Chart 4.—Causes of dyspepsia in 2,045 cases in which the primary complaint was dyspepsia.

4 are outlined in order of frequency the causes of indigestion in this group, which included 2,045 patients.

The incidence of functional causes in this group was relatively high. Next in importance was peptic ulcer, which accounted for the dyspepsia of about one in six

of the total number of patients. About one in eight of the patients was found to harbor cholecystic disease. Of greater importance is the fact that carcinoma of the stomach was the fourth most frequent cause, and it will be remembered that the group includes patients of all ages. It is interesting to note that chronic appendicitis was considered to be the cause of the dyspepsia in only 2.9 per cent of the cases, or only half as frequently as cancer of the stomach.

Males		Females	
Functional	29%	Functional	38%
Chronic appendicitis	15%	Chronic appendicitis	16%

Undetermined	2%		

Chart 5.—Causes of dyspepsia in males and females aged from 15 to 24 with a primary complaint of dyspepsia.

Causes of Dyspepsia at Various Ages.—Although in a review comprising all ages it is of academic interest to know what the most common causes of indigestion are, it soon becomes apparent that there must be wide variation in the relative importance of the various causative diseases at different ages. Consider, for example, the incidence of cancer of the stomach. Only 3 per cent of the total of 4,223 dyspeptic patients were found to be suffering from this disease. Obviously the chance of finding cancer as the explanation for chronic dyspepsia in a man over 50 would be far in excess of this figure; actually it would be at least six times greater.

Similarly, functional disturbances which might account for the dyspepsia in a greater number of young patients could hardly be assumed to be of equal etiologic importance in patients beyond the age of 50. Some interesting and important data soon become evident when we review the various causes of dyspepsia at different ages.

Ages from 15 to 24.—In chart 5 are indicated the most frequent causes of dyspepsia in patients in this age group who came to the clinic primarily because of dyspepsia. The sexes are considered separately. A complete analysis was made of all the diseases responsible for indigestion in this group, and these were arranged according to the classification of dyspepsias outlined earlier.

We were rather interested to find the relative importance of functional types of indigestion among young patients whose symptoms of dyspepsia were sufficiently distressing to prompt them to seek relief at the clinic. Chronic appendicitis, although usually considered a disease frequently productive of chronic dyspepsia, was responsible for indigestion about half as frequently as were the functional types of dyspepsia. Peptic ulcer was found to be an important cause of dyspepsia among the males; it was unimportant among the females. Migraine was not an uncommon diagnosis for each sex. Cholecystic disease was of some importance in the causation of dyspepsia, especially among the young female patients.

In addition to the diseases indicated in chart 5 as being the most frequent causes of dyspepsia in this

group were many others, such as cardiospasm, nephritis, intestinal infestation with parasites, food allergy, terminal ileitis and, though rare, malignant process of the gastrointestinal tract. It is interesting to note that although these young patients came for examination primarily because of dyspepsia, in only one of twenty instances was the dyspepsia found to be caused by an organic disease of the stomach or duodenum. This is at great variance with the findings for patients of more mature age.

Ages from 25 to 39.—In chart 6 are listed the most frequent causes of dyspepsia in men and women between the ages of 25 and 39 whose primary complaint was indigestion. In this group functional disturbances were still of primary importance. There was only a slight predominance in regard to women. Next in importance for the men was peptic ulcer, which accounted for better than one in four of the cases in this group. The location of the ulcers is of some interest: Ninety-eight were in the duodenum and only one in the stomach. Peptic ulcer was only about a fourth as common among the women as among the men. Cholecystic disease was the cause of indigestion about twice as frequently as peptic ulcer among the women. In 5 per cent of the men the dyspepsia was assumed to be due to disease of the gallbladder.

Migraine and constipation were relatively common causes of dyspepsia. Chronic appendicitis was considered the etiologic factor less frequently among patients in this age group than in younger persons. Cancer of the stomach begins to appear as a causative factor for dyspepsia among the men of this age. Among the 750 women in this group there was no instance of carcinoma of the stomach and only one of cancer of the colon. This is rather significant when one considers the fact that of the men of this age who had indigestion sixteen were found to have cancer of the gastrointestinal tract.

Relatively important, though less common, among the causes of indigestion in the men were gastritis, diseases of the urinary system (especially disease of the kidney and ureteral stone) epilepsy, endocarditis

Males		Females	
Functional	37%	Functional	42%
Peptic ulcer	27%	Cholecystic disease	14%
Cholecystic disease	5%	Peptic ulcer	7%
Chronic appendicitis	3%	Migraine	6%
Constipation	3%	Constipation	5%
Migraine	3%	Chronic appendicitis	5%
Types of dyspepsia (total cases)			
Organic	11%		
Reflex	18%		
Systemic	36%		
Functional	34%		
Undetermined	1%		

Chart 6.—Causes of dyspepsia in men and women aged from 25 to 39 with a primary complaint of dyspepsia.

and rectal fissure or fistula. Among women the more frequent causes other than those listed were endocarditis, allergy, disease of bone, organic nervous disease (brain tumor and epilepsy), genitourinary disease and hyperthyroidism. General classification of the diseases responsible for the symptoms of dyspepsia in this group reveals the fact that organic disease of the stomach and duodenum was a cause of symptoms more than twice as frequently as in younger patients. Reflex disturbances were less frequent causes than in the

younger group; systemic diseases and functional disturbances accounted for the complaints in 36 and 34 per cent, respectively.

Patients of 40 and Older.—In chart 7 are listed the most frequent causes of dyspepsia in men and women of 40 and older who presented themselves for examination primarily because of dyspepsia. It soon becomes apparent when one considers the cause of dyspepsia in these patients that the condition must be considered as of grave importance. Whereas in the younger age groups functional disturbances were one of the principal causes of dyspepsia, they now begin to assume a role of decidedly less importance.

Approximately one in four of the women in this group was found to have cholecystic disease; peptic ulcer remained a disease of importance, and cancer of the gastrointestinal or the accessory gastrointestinal tract was found to account for the dyspepsia of 5.8 per cent of the women. Cardiovascular disease was a relatively frequent cause. Cancer of the stomach, although less frequently the cause of indigestion in the women than in the men of this age group, nevertheless

ulcer, cholecystitis or cancer of the gastrointestinal or the accessory gastrointestinal tract.

Classifying the causes of dyspepsia in patients of 40 or older who sought medical aid primarily because of indigestion, we find that in 32 per cent the dyspepsia was due to organic disease of the stomach or duodenum, in 28 per cent was a reflex type of indigestion, in 20 per cent was a functional type and in 18 per cent was due to systemic causes. In 2 per cent of the cases no diagnosis was possible. It is rather a significant fact that more than six times as many patients in this age group as in the group aged from 15 to 24 had organic disease of the stomach or duodenum as the cause of their dyspepsia.

SUMMARY

Dyspepsia is one of the most common of the unpleasant experiences to which man is heir. About half of 10,000 patients between the ages of 30 and 60 complained of varying degrees of digestive difficulties.

Chronic Appendicitis.—The causal relationship of the chronically inflamed appendix to recurring dyspepsia has been the subject of much controversy. As a cause of dyspepsia it was considered of importance in only 2.2 per cent of the 4,223 cases included in this series. Most of the patients were young; appendicitis was assumed to be the cause of the indigestion in 15 per cent of the young males between 15 and 24 and in 16 per cent of the females of the same age. In many the condition should probably more accurately have been classified as subacute appendicitis. There was a sharp drop in the incidence of this disease among patients between the ages of 25 and 39, the incidence for this group being 3 plus per cent for men and 4 plus per cent for women. In only 2 per cent of the women older than 39 who came to the clinic primarily because of indigestion was chronic appendicitis considered the cause of the complaint. In only seven of the 1,377 men of this age group did chronic dyspepsia seem explainable on the basis of chronic appendicitis. Though appendicitis may occasionally produce a periodically reappearing indigestion, it would seem to us that appendectomy for this cause after the age of 25 usually produces a therapeutic result disappointing equally to the patient and to the surgeon.

Functional Dyspepsia.—The stresses of life in this day and age exact quite a toll among those who choose to participate vigorously in its race. The resulting nervous and physical exhaustion, worry, depression and various psychic insults not infrequently produce changes in the normally smooth, rhythmic behavior of the chemical and motor mechanics of digestion, and the incident disturbances of function cause dyspepsia. It is not surprising that the highest incidence of functional disturbance in indigestion should occur between the ages of 25 and 39. Almost half of the women of this age who presented themselves primarily because of dyspepsia had dyspepsia of the functional type. The incidence of functional dyspepsia among the men of this age was also high, 37 per cent. Functional types of indigestion were also common among patients between the ages of 15 and 24; 29 per cent of the men and 38 per cent of the women were considered to have a functional type of indigestion. After the age of 40 the relative importance of functional dyspepsia became less, mainly because by this time more significant diseases had developed.

Peptic Ulcer.—This was second in frequency as a cause of dyspepsia among the 4,223 patients. Among men older than 39 who came for examination because

Chart 7.—Causes of dyspepsia in men and women of 40 or older who had a primary complaint of dyspepsia.

was a formidable etiologic factor. Another disease frequently responsible among the women was migraine. Appendicitis was considered responsible in only 2 per cent of the women. Hyperthyroidism, diaphragmatic hernia and pelvic diseases were other causes. Of the women in this group, therefore, 38 per cent had indigestion which was caused by diseases of the gallbladder, by peptic ulcer or by cancer of the gastrointestinal or the accessory gastrointestinal tract.

The most frequent cause of dyspepsia in the men of this group was peptic ulcer; functional indigestion was next. What seems to us to be of significance is the fact that one in six of all the men of 40 years or more who came to the clinic with the primary complaint of indigestion were found to have cancer of the gastrointestinal or the accessory gastrointestinal tract. One in eight of the men in this group was found to have cancer of the stomach. Cholecystic disease accounted for more than 9 per cent of indigestion in this group and cardiovascular disease for 5 per cent. Other frequent causes of dyspepsia were constipation, migraine, arthritis, syphilis, disease of the rectum, chronic alcoholism, cardiospasm and organic nervous disease. About half of the men of this group were found to have peptic

of indigestion it was the most frequent cause of dyspepsia. According to sex, peptic ulcer was four times as common among men as among women. The ulcers were predominantly duodenal. Gastric ulcer predominated among young males and among women beyond the age of 40; duodenal ulcer predominated in men between the ages of 25 and 40. Recurrent dyspepsia should always bring up for differential consideration the possibility of peptic ulcer.

Cholecystic Disease.—Disease of the gallbladder was one of the most common causes of dyspepsia. Among women it was surpassed in frequency only by functional disturbances. Among women past 39 it was the most common cause. There was less than half as much cholecystic disease among men as among women. Even among men, however, it was a frequent cause of indigestion, being fourth in order of frequency among the total number of patients comprising the series. One in eight of all women between the ages of 25 and 39 who presented themselves because of indigestion was found to have disease of the gallbladder. It was found to be the cause of indigestion in women older than 39 in about every fourth case. Although much less common among the causes of dyspepsia in young men and women, it was found to account for indigestion in 1.4 per cent of the males and in 3 per cent of the females.

Cancer.—Although not the most common among the causes of indigestion, cancer is certainly the most important. Failure to recognize cholecystic disease or peptic ulcer is a lamentable mistake; failure to recognize cancer is a fatal error. The incidence of cancer of the stomach in the 4,223 cases was 3 per cent. If we scrutinize these cases more carefully and consider the incidence of cancer of the stomach among patients whose salient complaint was dyspepsia, we find that the probability of the presence of this disease has almost doubled. If we then separate these cases further and consider the importance of cancer as a cause of indigestion among men of 40 or older who considered dyspepsia their major difficulty, we discover the startling fact that one in six had cancer of the gastrointestinal or the accessory gastrointestinal tract. One in eight actually had cancer of the stomach. Even men of this age who came for other causes but who also had some minor difficulties affecting their digestive tract were found to have cancer of the gastrointestinal or the accessory gastrointestinal tract in 4.8 per cent of cases. Cancer as a cause of the indigestion was relatively less common among the women. In the 4,223 cases there was no instance of gastric cancer among women less than 40 years of age. Above that age cancer of the stomach was found in 4.5 per cent of the women who came to the clinic because of dyspepsia, about a third as frequently as among the men.

CONCLUSIONS

Symptoms of chronic dyspepsia must always be evaluated carefully. All available methods of diagnosis should be utilized to obtain exact knowledge regarding its underlying cause. This is particularly important if the patient has reached the age of 40 years, when dyspepsia must be considered of grave significance until it is proved otherwise. Physicians seem to be especially dilatory and procrastinating regarding their own personal dyspeptic experiences, assuming some sort of professional immunity to gastrointestinal disease which may be very grave. This accounts for the fact that cancer of the stomach is detected no earlier among them than among their patients.

It would seem to us that the layman must be educated to realize the risk he takes when, with advancing age, he seeks relief for an ailing stomach by taking the advice of some radio announcer, drug clerk or other vendor of therapeutic nostrums.

THE CUTANEOUS HISTAMINE REACTION AS A TEST OF PERIPHERAL NERVE FUNCTION

LEWIS H. LOESER, M.D.

NEWARK, N. J.

Histamine has come into use as a test for circulatory function in the extremities and as a drug of more general usage. Since the work of Sollmann and Pilcher,¹ Eppinger² and Hess³ and under the influence of the experimental work of Lewis,⁴ the drug has taken its place in several fields of medical practice. Its use as a test of circulatory function and as a stimulant of gastric secretion is too well known to need description.

The cutaneous reaction to histamine is a triple response consisting of (1) a purple spot at the site of the puncture; this is usually obscured quickly by (2) the formation of a wheal, (3) the later appearance of an extended area of arterial dilatation—the flare. The ultimate picture closely resembles a mosquito bite—a wheal surrounded by a flare of redness averaging from one-half to 2 inches (1.3 to 5 cm.) in diameter. It is in the flare that my interest centers.

Until 1927, when Sir Thomas Lewis⁴ published his monograph, a clear understanding of the physiology of the cutaneous histamine reaction was lacking. Much speculation and theory existed. Bruce⁵ in 1910 had observed that when the cutaneous nerve was degenerated no flare reaction was found. He postulated the presence of an "axon reflex" by which a stimulus would travel up one branch of a sensory nerve and down another branch to adjacent parts of the skin without utilizing a nerve cell in the entire reflex. His observations on the reactions of the conjunctiva to mustard oil apparently confirmed this view.

Müller⁶ in 1913 observed that the flare was absent in a number of injuries to the spinal cord, at a point corresponding to the site of the injury. He came to the conclusion that the flare was dependent on a spinal reflex arc, mediated through the pathway of the spinal cord as well as through the peripheral nerves. His views influenced others, notably Ebbecke⁷ and Krogh,⁸ who came to the same conclusion after similar experiences. These workers, including Müller, failed to take into account the probable injury to the nerve roots and ganglions in destructive lesions of the spine.

Lewis and his co-workers, dissatisfied with the current speculation on this subject, proceeded to investigate the phenomena. As a result of their work, certain facts were made clear:

1. The wheal develops as a local reaction to the irritant drug and is independent of the nerve supply.

1. Sollmann, Torald, and Pilcher, J. D.: *Endermic Reaction*, J. Pharmacol. & Exper. Therap. 9: 399 (March) 1917.

8. Krogh, August: *The Anatomy and Physiology of Capillaries*, Yale University Press, New Haven, Conn., 1922.

2. The flare is a local phenomenon which is not immediately abolished by regional anesthesia or by section of the peripheral nerve. It is of neural origin and depends on a purely local nervous reflex. The reflex is, however, dependent on the integrity of the peripheral sensory nerve. After section of the nerve, from six to eight days being allowed for degeneration to set in, the flare is no longer obtained. Section of the nerve at any point from the spinal ganglion to the skin will abolish the flare after sufficient time has elapsed to allow the nerve to degenerate.

These facts have not been utilized in actual practice. Neurologists in particular should have noted these experiments and adapted them to their needs. Here is a simple test, easy to interpret, requiring no laboratory equipment. While the interpretation is restricted to the integrity of the peripheral sensory nerves, by implication and deduction a wide field of usefulness is uncovered. Other than the cranial nerves, the peripheral nerves in the body are mixed nerves, carrying both motor and sensory fibers, so that the integrity of the nerve as a whole can be tested by determining the status of the sensory fibers.

TECHNIC OF TESTING

I have used histamine hydrochloride in 1:1,000 solution. The solution is kept in rubber stoppered vials and apparently does not deteriorate at room temperature over a period of months. Two methods of injection are used. In one I employ a tuberculin syringe and fine hypodermic needle. With this an amount as small as 0.01 cc. is sufficient when injected intradermally. The other method utilizes a spring punch device originally devised for obtaining a drop of blood for blood counts. The blade has been ground down so that only a fine puncture is made into the skin. The initial drop of blood is wiped away and a drop of histamine solution is deposited by contact over the puncture. This can be wiped away after contact of a few minutes.

The injections are made from 1 to 3 inches (2.5 to 7.5 cm.) apart across the area to be tested. By careful choice of sites a definite area can be outlined. In some cases only a single injection is necessary to confirm the clinical observations. In testing for segmental levels a single row of injections, about 1 inch apart, will suffice.

The test should be done quickly so that too much time does not elapse between the first and the last injection. One can then compare the various responses.

The reactions, for clinical purposes, are graded from 0 to 4 plus, according to the amount and intensity of the flare. A wheal with no flare is graded as zero (0). A wheal surrounded by an intense flare about the size of a half dollar (30 mm.) is graded 4 plus. Responses differ in certain parts of the body. Familiarity with the test increases the accuracy of the interpretations.

Variations in reaction are seen. Irregular or patchy flares are frequently seen in partly degenerated or in regenerated nerves after injury. The wheal should form within twenty seconds to one minute. The flare, which is the important factor in the test, appears later, reaches its height in from three to five minutes and begins to fade after from seven to ten minutes. Variations from the normal include delay or decrease in extent or time of reaction. This may be caused by: (a) partial degeneration of the peripheral nerve, (b) interference with the vascular supply of the area tested and (c) errors in technic of injection.

Tests should not be performed on those parts of the skin in which circulation is deficient. This applies not only to extremities with diseased blood vessels but also to the selection of sites at which the skin is normally under pressure, such as in the neighborhood of joints or over the malleoli.

During the past three years I have found the histamine test useful in a wide variety of cases. In many instances the test merely confirms conclusions made obvious by clinical observation. Occasionally it acts as a visible means of demonstrating conclusions to others who might otherwise remain unconvinced. In a few cases this test has been of extreme diagnostic importance.

The histamine test for peripheral nerve function has been found to be of value along the following lines:

1. To determine the presence of degeneration and later regeneration in peripheral nerves following injury. Traumatic lesions to nerves, sufficient in extent to interrupt the integrity of the peripheral nerve, will abolish the flare reaction after from six to eight days has elapsed. In my experience, the absence of flare frequently precedes the electrical reaction of degeneration by several days. Conversely, the flare begins to return in the area supplied by the regenerating nerve considerably earlier than the electrical reactions begin to change. In this way this technic is useful in determining the extent and duration of peripheral nerve injury.

2. To differentiate hysterical from organic anesthesia. Certain cases of hysterical anesthesia closely simulate organic anesthesia, and even the expert occasionally finds the problem perplexing. Not all physicians are skilled in this field, and the problem for the unskilled is not at all simple. The histamine reaction in which from six to eight days is allowed to elapse for degeneration is an effective test in this group of cases; particularly in medicolegal work, in which, following repeated examinations, anesthetics are frequently seen closely simulating the organic.

The test is also of value in those cases in which an actual organic anesthesia is present with a superimposed hysteria. In these cases, the sensory tests, being dependent on the cooperation of the patient, are frequently unreliable. The histamine test provides an accurate method of delimiting the true extent of anesthesia and is obviously independent of the patient's subjective response.

3. To differentiate the sensory anesthetics of malingering from the organic. The problem here is quite similar to that in hysteria. The neurologist of today is not infrequently asked to examine litigants who have been carefully coached and advised as to their symptoms. Complaints of anesthesia are not uncommon following injuries to the trunk and extremities. The histamine test demonstrates in a convincing manner the absence or presence of true dermal anesthesia.

4. As an additional aid in the localization of lesions of the spinal cord. In expanding lesions and in some compressing lesions of the spinal cord there is occasionally interference with the function of the ganglion of the posterior root. If two or more ganglia are involved, a segmental area of the skin at the upper level of the lesion will give a negative response to histamine. This has been demonstrated in one case presenting a tumor of the spinal cord and in several cases presenting fractured vertebrae with compression of the cord. Müller⁶ used the histamine test for this purpose as far back as 1913.

5. In the differentiation of nerve root from spinal cord involvement. This differentiation is particularly valuable in lesions of the lower part of the spine where it is necessary to distinguish between lesions of the cauda equina and lesions of the lower part of the spinal cord. The histamine test is negative (no flare) in the anesthetic area when the lesion involves the nerve roots but is normal if the anesthesia is the result of injury to the spinal cord.

6. To demonstrate to skeptical observers, laymen and the like, the presence or absence of anesthesia of peripheral nerve origin. When normal control areas are used the demonstration is very convincing, particularly in cases in which a negative reaction on one side can be compared with a positive reaction on the opposite side.

As a result of experience with the histamine reaction as a test of nerve function, I feel that the test is of more than passing value. I present nothing new in thus urging its use, for other observers have utilized the reaction in this manner in previous years. Their conclusions and reports have for the most part been found only in technical publications and have not been put to clinical use. A valuable addition to the armamentarium of the physician has thus been neglected. It is a reliable and simple procedure to test the function of peripheral nerves and, as such, should be more widely utilized.

RECURRENT DIARRHEA DUE TO DYSENTERY ORGANISMS

SIDNEY A. PORTIS, M.D.

Consulting Physician, Cook County Hospital
CHICAGO

The frequency of persistent diarrhea, with or without a known history of a previous acute intestinal infection, stimulated me to investigate the etiologic factors associated with this symptom. With apparently negative results from examination of the stool, a fairly large percentage of patients yielded positive agglutinations in the blood serum for one or more of the organisms of the dysentery group in relatively high titers. Agglutinins have long been known to have an immunologic reaction in the patient's serum against the dysentery bacillus.

Davison¹ in 1920 studied a series of 134 cases of bacillary dysentery in children. He used the agglutination test in addition to bacteriologic methods for diagnosis and considered an agglutination of 1:50 or above an indication of previous or present dysentery infection. In infants he considered 1:20 as suggestive. He found that the maximum titer occurred from the seventeenth to the twenty-first day after the onset of the disease, and the agglutinins continued to be present for from four to six months. Three patients with diarrhea were negative culturally but gave positive agglutinations.

In the same year M'Leod and Ritchie² reported on the serum reaction in bacillary dysentery. Eighty-three

per cent of their patients from whose stools *B. dysenteriae* had been isolated gave positive results serologically; 100 normal persons gave negative results, and of 194 patients with diarrhea who gave negative results bacteriologically, 12.8 per cent showed positive agglutinations.

A study of bacillary dysentery in asylum patients was reported by Dawson and Moodie³ in the following year. Because agglutinations were present only after the fourth week of the disease, they considered the agglutination test of little diagnostic value in acute cases.

A few months later Gardner⁴ disproved the work of Dawson and Moodie. He stressed the importance of using standardized suspensions and of finding the normal limits of the antigen by testing it with a group of suspensions from normal persons or against a previously tested suspension.

In 1922 Patterson and Williams⁵ reported some observations on dysentery bacilli of the Sonne type and concluded that the agglutination test was extremely valuable in the diagnosis of chronic bacillary dysentery. They considered a titer of 1:80 or above as indicative of an etiologic connection.

Widowitz⁶ in 1923, after working on the agglutinations of dysentery bacilli in children, came to the conclusion that the formation of agglutinins is a definite indication of present or previous infection and that so-called normal agglutinins are remnants of real agglutinins.

Agglutination tests with Flexner dysentery bacilli were run on 161 blood specimens from tuberculosis suspects and on thirteen from normal persons. The results were reported by Hull and Henkes⁷ in 1923. The specimen from only one of the normal persons was faintly positive. They concluded that persons in the incipient stage of tuberculosis showed positive agglutination with the Flexner bacillus while those in the advanced stage did not react.

The Aberdeen epidemic of milk-borne bacillary dysentery was studied by Kinloch⁸ in 1923. By means of the agglutination test he was able to detect a carrier who had played an important role in the spread of the disease.

In 1923 Gardner,⁹ after working on the agglutination standard in bacillary dysentery, stated that one or more repetitions of the test at intervals of from three to four days was the best way to establish the presence of an infection.

Major Ash¹⁰ in 1923, in discussing the diagnosis of bacillary dysentery, stated that serologic studies should be done but are not very dependable.

In the next year Guimarães¹¹ worked on the sero-diagnosis of bacillary dysentery and got very favorable

results. He found it especially valuable in ruling out colitis and typhoid.

In 1924 Petrie¹² reported on the diagnosis of dysenteric infections in patients in mental hospitals. Although he believed that the agglutination test was inconsistent, he found it helpful in diagnosing chronic cases and in detecting carriers and thought it should be a routine procedure in such institutions.

Widowitz¹³ in 1924 reported some additional work on dysentery agglutination in children and found that the blood of even very young infants produces specific agglutinins. He stated that a positive reaction definitely proves a present or past infection.

In 1925 Hilliard¹⁴ reported a careful study of dysentery on patients in mental hospitals. He found that typhoid vaccine increased the agglutinating titer against the Flexner bacillus for about one month. He found the agglutination reaction well defined by the end of two months and persistent thereafter.

Fyre¹⁵ in 1927 investigated an epidemic of Sonne dysentery. He used the agglutination test in addition to cultural methods for diagnosis. He found no significant titer until after the first week.

In 1928 Menton¹⁶ after examining forty-seven specimens of blood, concluded that a negative agglutination reaction does not exclude bacillary dysentery and that isolation of the organism is essential in diagnosis.

The following year he reported a study of agglutinins to *B. dysenteriae* in apparently healthy persons.¹⁷ He made 524 tests, and thirty-three persons gave positive reactions. These thirty-three persons all came from crowded sections, and six of them gave histories of previous diarrhea.

Smith and Fraser¹⁸ in 1930 reported the results of agglutination reaction in relation to Sonne dysentery. They studied forty-eight patients with Sonne dysentery and 138 controls and found the test valuable in diagnosis. The percentage of positive reactions was highest after the fifteenth day of the disease.

In the same year de Lavergne, Melnotte and Debenedetti,¹⁹ after a careful study, concluded that the agglutination test was valuable even after many months and that the agglutination titer was always much lower in the control group.

Mackie²⁰ in 1932 reported that the agglutination test was sometimes helpful in differentiating chronic bacillary dysentery from chronic ulcerative colitis.

In 1934 Felsen and Osofsky²¹ studied an epidemic of Sonne dysentery and found that the agglutination test was valuable in diagnosing mild and symptomless attacks and in detecting carriers. They found that arthritis is frequently associated with the Sonne bacillus infection.

The following year Felsen and Osofsky²² reported some additional work on 300 control cases. By use of the agglutination test they discovered twenty cases of chronic bacillary dysentery which had been diagnosed as nonspecific ulcerative colitis; 23 per cent of their control group showed positive agglutinations.

Cases of acute and chronic bacillary dysentery were investigated by Felsen²³ in 1936. He found that long after the dysentery organisms disappear from the feces the intestinal lesions persist and the agglutination titer remains high. With Sonne dysentery, however, the titer may never have exceeded 1:50. Results of agglutination tests showed that many cases of nonspecific colitis had at first been bacillary dysentery.

In the same year Manson-Bahr²⁴ reported a careful study of the differential diagnosis of colon diseases. He found the agglutination test valuable in the chronic stages in order to differentiate it from colitis.

The clinical picture of this disease is bizarre. However, there is practically always a history of a previous acute diarrheal episode, which may have lasted from a few days to a few weeks. Then, for some unknown reason, periods of diarrhea recur from time to time and in some cases may even persist for months. If diarrhea persists long enough, the patient may show the usual signs of loss of weight and emaciation. Fecal examination of these persons may occasionally show some pus but rarely blood, unless there is an acute aspect to the condition. In a small percentage of examinations the etiologic organism may be recovered from the stool. Recently Silverman²⁵ of New Orleans devised a method of procuring more positive cultures from the stool by changing the intestinal flora from a proteolytic to an aciduric type.

Proctosigmoidoscopic examination, unless there is secondary infection, reveals no significant changes. The mucosa is blanched; the minute blood vessels stand out on the pale mucosa. Rarely, if ever, does one see ulcers; if they are present they are most likely small secondary lesions. Roentgenologically there are no pathognomonic signs. The haustral markings may be absent; there may be some tubalization of the descending colon and, in all cases, with barium enemas, not once was any unusual narrowing of the ileum noted similar to that found in regional ileocolitis. The most frequent complication of this disease is an arthritis, which may be monarticular in type, resembling an allergic joint, and as a complicating factor it was quite frequent in my group of cases. This is in agreement with the observations of Felsen.

Therefore the diagnosis of this condition must rest with the examination of the blood serum. A previous dysentery infection should be suspected in any patient who for some unknown reason has a persistent diarrhea that does not respond to ordinary methods of treatment after careful examination has ruled out the more common causes of diarrhea, particularly in view of the negative results on examination of the stool. Many patients date their trouble to the World War, and more recently there have been epidemics in Chicago resulting in subsequent outbreaks of paroxysmal diarrhea, which

have been faultily ascribed to many other etiologic factors than are herein presented.

Seven years ago, after a careful search for the causes of persistent diarrhea, I found a high agglutinin titer for the various organisms of the dysentery group. Since then I have seen approximately ninety cases in which the blood serum gave a relatively high agglutination for

one of the various organisms of this group. The interesting feature of this and subsequent studies, carried out at the Cook County Hospital, was that the Strong and Sonne bacilli were for the most part the causative organisms of the disease. Most laboratories in this community and elsewhere test for the Hiss Y, Shiga and Flexner bacilli and relatively few for the Strong and Sonne types. I am sure that this is the reason many cases remain undiagnosed.

In the technic followed, agglutinations in dilutions of 1:20, 1:40, 1:80, 1:160, 1:320, 1:640 and 1:1,280 were used, with a control tube for each. Each serum was run with Strong, Sonne, Shiga, Hiss Y and Flexner bacilli. Suspensions treated with solutions of formaldehyde, which are considered most reliable, were used and were tested at intervals of from one to two

weeks for purity and agglutinability against known antisera. All suspensions were made from smooth colonies. Sonne showed the greatest tendency to dissociate into rough variants and had to be transferred most often. Agglutinations were placed in an incubator at 35 C. (95 F.) for four hours and at room temperature for two hours before a reading was made. All readings were made with a magnifying lens.

From April 15 to Oct. 1, 1937, 237 cases of diarrhea were studied at the Cook County Hospital and 256 serial agglutinations were made, which consisted of the patient's serum tested against the Strong, Sonne, Shiga, Hiss Y and Flexner bacilli. In fifty-three of the 237 cases there were negative agglutinations (table 1). It might be said at the outset that agglutinations of 1:80 or above were considered diagnostic of a previous dysentery infection. Ninety-seven patients gave positive agglutinations of 1:80 and above for the Strong bacillus, twenty-six for Sonne, seven for Shiga, thirty for Hiss Y and sixteen for Flexner, making a total of 176 of these 237 patients positive for one of the various organisms of the dysentery group in dilutions of 1:80

or above. The Strong bacillus was by far the most prominent organism of the group to give a high titer of agglutinins.

Table 2 illustrates the studies of 144 patients selected at random who came to the hospital for other than diarrheal conditions. This group of cases was selected to see whether relatively high titers could be obtained in patients who had no recollection of a previous dysentery infection or who associated their diarrhea with an ordinary gastrointestinal upset. Of these 144 cases, twenty-nine were negative for all organisms and eighty-one gave a positive agglutination of 1:80 or above for the various organisms. These are further subdivided into forty-eight for Strong, eight for Sonne, seven for Shiga, nine for Hiss Y and nine for Flexner. In the diarrheal conditions the percentage of positive agglutinations in the blood was 79; in the control cases the percentage was 56. It is difficult in the control series to go into the history of all the patients because they were scattered throughout the hospital and many were

Flexner.....	5 (22 per cent)
Hiss Y.....	0

in the outpatient clinic. However, it is reasonable to suppose that these eighty-one patients who gave a positive agglutination must have been exposed at some time or other to dysentery, if any credence is to be placed in the specificity of the agglutinations for these organisms. There is enough evidence in the literature and in the currently described work to support this contention.

As indicated in table 3, 133 of the patients with diarrhea had cultures of their stools made as a routine by the ordinary methods for obtaining positive dysenteric cultures; 111 of them gave negative reactions; twenty-two, or 16 per cent, gave positive reactions. Of the twenty-two, eleven, or 50 per cent, gave positive agglutinations for Strong; six, or 27 per cent, for Sonne, and five, or 22 per cent, for Flexner. No Shiga or Hiss Y bacilli were recovered in any of the positive stools.

TABLE 4.—Office Patients with History of Diarrhea:

									67

Table 4 shows that from March 2, 1937, to April 1, 1938, 104 consecutive patients complaining of diarrhea were tested at my office. Forty-five of them gave positive agglutinations for one or more organisms of the dysentery group. Previously the agglutination tests had been done by outside laboratories, which accounts for the lack of control data for the other reported forty-five cases. Of the 104 patients who presented them-

selves for diarrhea, approximately 45 per cent had positive agglutinations. In table 4, thirty-two of these patients gave agglutinations of 1:80 or above for the Strong, four for the Sonne, two for the Shiga, sixteen for the Hiss Y and nine for the Flexner. Of these forty-five total positive cases, therefore, there were sixty-three agglutinations of 1:80 or above for the various organisms of the dysentery group. It is interesting to note that seventeen of the thirty-two agglutinations for the Strong type were 320 or above and that the others had correspondingly high titers.

COMMENT

Many patients complained of having had diarrhea for a period of years and gave negative results in the stool. The importance of making routine examinations of their serums is self evident. The data herein presented are suggestive that *B. dysenteriae* may infect a patient and later lead to recurrent diarrhea. The modus operandi of the clinical picture may be related to an allergic manifestation in which a sensitized intestine reacts to the antigen of the organism. The paroxysmal attack may resemble other bacterial allergic phases or it may resemble Shwartzman's phenomenon. The infrequency of the presence of the organism in the stool of the patient may suggest localization in the intestinal wall or, more logically, in the regional lymph glands. The cycle of the diarrhea is interdependent on the ability of the host to counteract the offending organism or its toxins. Further studies will have to be carried out to substantiate this point of view. The interesting feature is that, in a small group of control patients, after adequate therapeutic approach, the titer of agglutinins disappeared from the blood serum on subsequent examination. It should also prove enlightening to observe untreated patients during a quiescent period, to see whether the agglutinating titer remains as high or is absent when the diarrhea is in complete abeyance. This feature of the clinical picture is in the process of elaboration. I think it is justifiable to conclude that the bacillus of dysentery may infect a patient, the acute picture may subside and subsequent paroxysmal diarrhea may owe its origin to a previous infection based on the evidence of high agglutinating titer in the blood and in the absence of positive changes in the stool.

Except in relatively few cases, no attempt at a therapeutic regimen was carried out on any of the patients at the Cook County Hospital. However, those in my private service were subjected to the following therapy:

If the patient was critically ill, and occasionally he became so, he was hospitalized, placed on a high vitamin nonresidue diet and, if he showed no previous sensitizations, he was given a polyvalent antidysentery serum, beginning with 10 cc. the first day, 20 cc. the second day, 30 cc. the third day, 40 cc. the fourth day and 50 cc. on each of the fifth and sixth days. Following this program some serum sickness usually developed, which could be controlled by the ordinary methods. After the serum therapy the patient was given gradually increasing doses of a polyvalent or monovalent vaccine, depending on the specificity of the titer of the agglutinins in the blood. If the patient was ambulatory no serum was usually given, but he was started out immediately on a high vitamin nonresidue diet and given gradually increasing doses of the vaccine.

For specific treatment other than serum therapy, two types of stock vaccine were employed, one for oral and the other for hypodermic use. These were in polyvalent mixtures as well as in single strains. However, because of increased local and general toxic reactions, the Shiga

organism was not used in the polyvalent mixtures. The oral vaccine contained 50 billion organisms per capsule; the hypodermic solution contained one billion organisms per cubic centimeter.

Patients receiving the oral vaccine took one capsule daily, half an hour before breakfast. If symptoms in the intestine were increased the dose was immediately reduced or the hypodermic vaccine given, since with the latter the dosage could be controlled more easily. With a decrease in symptoms in the intestine after from two to four weeks, the oral vaccine was given every second or third day and gradually decreased to one capsule weekly, provided the patient remained free from symptoms. The oral method was tried out because of the experience of some Russian investigators,²⁶ but in our hands it was not very effective.

The hypodermic vaccine was started at 0.1 cc. dose, subsequent doses being increased by that amount, unless a local or systemic reaction occurred, whereupon the dosage was either maintained or decreased. The schedule producing the best results is as follows:

Three injections a week for three weeks.

Two injections a week for three weeks.

One injection a week for six weeks.

One injection every two weeks for several months until the symptoms are in complete abeyance.

Variations, however, occur with the difference in the needs of the individual. In general the hypodermic vaccine gave better results.

The therapeutic results in these cases may be open to some question because one might possibly feel that one is dealing with nothing more than a reaction to a foreign protein injected into a patient. I have no proof to offer for the specificity of this form of treatment. Certainly further controls will have to be made in order to substantiate whether or not this is a specific reaction. I might say that in several of these cases, previous to the use of these vaccines, Borgen's vaccine filtrate and Borgen's immune serum gave no results in the few cases in which they were tried, and the patients did respond to the dysentery vaccine. Therefore I am merely offering this evidence as an observation on my part in order to be of some assistance in the treatment of these cases of unexplained diarrhea.

CONCLUSIONS

1. Recurrent diarrheas may be due to dysentery organisms.

2. Patients may become infected with bacillary dysentery organisms and later show agglutinins in the blood serum for the offending organism. These agglutinins remain for a long period of time.

3. Arthritis may be a complication of this form of dysentery.

4. In a relatively small number of cases the organism may be recovered from the stool.

5. Diarrhea associated with this phenomenon may be controlled by gradually increasing doses of monovalent and polyvalent vaccine given hypodermically.

6. In acutely prostrated individuals, monovalent and polyvalent antidysentery serum may be of value.

7. Further observations must be made before one can arrive at conclusions regarding the specificity of this form of treatment.

AIR CONDITIONING AND INDUSTRIAL HEALTH

LEVERETT D. BRISTOL, M.D., DR.P.H.
NEW YORK

The practical application of scientific air conditioning to various industrial processes and manufacturing methods and equipment first became evident about 1905. Air conditioning for human comfort was provided originally about 1922 in motion picture theaters and during the last ten or fifteen years has been made available with gratifying results in restaurants, stores, hotels, private homes, office buildings and railroad cars. Air conditioning may be defined as the mechanical production of an artificial indoor atmosphere through the simultaneous and complete control of temperature, humidity, movement and purity during various seasons of the year. While proper ventilation in general is recognized as one of the essentials for the maintenance of indoor life and health, little scientific information or statistical data are available as to the influence of complete air conditioning on the health of industrial workers.

AIR CONDITIONING SYSTEMS

There are various types of so-called air conditioning systems now in vogue. "Air conditioning" is a loosely used term which may mean one thing from the point of view of one person and an entirely different thing from the point of view of another; in fact, the words "air conditioning" and "air conditioned" are often misused. The popularity of the idea and the appeal to comfort, particularly the cooling effects in hot weather, already have given rise to a number of different devices now on the market. A true air conditioning system in the accepted use of the term is one that will provide simultaneously the exact indoor air temperature, moisture content, movement and purity required for a particular purpose, despite outside weather conditions; it must make available a complete rather than a partial conditioning.

As a rule a system designed to give simultaneous and complete air conditioning in a large building draws outside air to a centrally located conditioning apparatus in the building, where it is brought into contact with a dense water mist. The temperature of this water mist is automatically controlled either by heating or by cooling and in this manner the moisture content of the air passing through it is controlled. The water spray also serves as a filter to remove impurities such as dust particles and soluble matter. As the air leaves the spray chamber it may be heated or cooled to the desired degree of temperature according to the season of the year, and it is then carried through ducts and distributed to various rooms. In the winter months artificial heat and increased humidity are required, while during the hot and humid summer months the conditioning not only must cool the indoor air through some form of refrigeration but also must dehumidify it. In the conditioning process the volume of air circulated also is automatically regulated and controlled.

PREVIOUS STUDIES

One of the leading air conditioning companies has deplored the amazing lack of authoritative information regarding the effects of air conditioning on human health and has invited medical research and investigation on the subject; in spite of this, little controlled scientific data of value are available. Up to the present,

most of the studies have been directed toward determinations of comfort effects, while a few comprehensive investigations on physiologic reactions have been carried on by various research workers representing such agencies as the American Society of Heating and Ventilating Engineers and the United States Public Health Service and Bureau of Mines.

SPECIAL STUDY

I had the opportunity to observe the results of air conditioning on the health of a particular group of industrial workers for a period of approximately three years. The system involved was one of the nationally recognized and approved complete air conditioning systems. The operating schedule of this air conditioning system was varied somewhat from time to time on a more or less experimental basis from the standpoints of comfort, effect on equipment, local weather conditions, season of the year, and current maintenance costs.

METHODS

In considering the possible effects of air conditioning on health, the difficulty in obtaining conclusive data must be recognized at the outset. Two approaches to a study of this nature are possible:

1. The positive approach, in which an attempt is made to measure the actual improvement in health and physiologic reactions based on careful periodic medical examinations, and studies of weight, nutrition, blood conditions, freedom from sickness and other factors relating to the positive health of each individual in the group.
2. The negative approach, in which an attempt is made to measure the amount, character and duration of sickness among members of an air conditioned group, as compared with a simultaneous control group not working in specially conditioned air.

In the study reported on, the positive approach would have involved considerable expense and a very close check-up on a large number of individuals, with possible disruption of routine service, as well as a hindrance caused by many variables which naturally would enter into such a study unless each individual in the group could be carefully controlled not only during hours of work but also during the entire twenty-four hours of each day. This investigation, therefore, is based on an analysis of the sickness experience of a group, compared with a suitable control group, as outlined under the negative approach mentioned.

GROUPS SELECTED

Approximately 1,000 female employees working in three or four air conditioned rooms in the same building were selected as the demonstration or study group, including only those having had at least two years of service at the beginning of the study and, so far as practicable, having had the same type of work during that time.

A control group of approximately the same number of women employees of about the same average age carrying on the same type of work in several other rooms of the same or nearby buildings under practically the same conditions, with the exception that they were working under ordinary conditions either of mechanical or of natural ventilation and not in so-called air conditioned space, was chosen for comparative study as to their sickness experience. The number of employees in each of the groups decreased somewhat and changed proportionately as the study progressed,

as the result of resignations, furloughs, change of place of work and other factors in connection with employment; therefore the sickness incidence rates, based on a slightly decreasing number of employees each month, have been computed and studied from the standpoint of number of cases per hundred employees.

STATISTICAL DATA

Two types of statistical data were available for this study, as follows: (a) those including cases of minor incidental sickness absence of seven days and less and (b) those based solely on cases of more serious illness lasting over seven days. Because of the fact that the number of cases of minor incidental absence of seven days and less may be subject to considerable distortion by unverified personal reasons for absence, and that many actual cases of brief illness may be recorded without a physician's diagnosis or certificate, it was decided to base this study on cases of sickness lasting more than seven days, all of which were reported and recorded on the basis of a physician's examination and diagnosis and were not liable to the influence of personal, employment and economic factors.

RESULTS

Table 1 gives a comparison of the average monthly incidence per hundred women employees of cases of sickness for periods lasting over seven days during thirty-three months of study in air conditioned and non-air conditioned groups.

TABLE 1.—Comparison of Average Monthly Incidence Rates of Cases of Sickness During Thirty-Three Months of Study

Group	Cases per 100 Employees	
	General Causes	Upper Respiratory Diseases
Air conditioned.....	1.62	0.72
Non-air conditioned.....	1.39	0.67

Table 2 gives a comparison of average days' duration per case of sickness for periods lasting over seven days, in air conditioned and non-air conditioned groups.

TABLE 2.—Comparison of Average Days' Duration per Case of Sickness During Thirty-Three Months of Study

Group	Average Days per Case	
	General Causes	Upper Respiratory Diseases
Air conditioned.....	41.5	29.7
Non-air conditioned.....	41.4	29.5

GENERAL COMMENTS

From this study there is no evidence to indicate any improvement in incidence or duration of sickness among a group of upward of 1,000 people working in scientifically controlled air conditioned space as compared with a control group of approximately the same size working in non-air conditioned quarters ventilated by the usual mechanical and natural methods.

The somewhat negative results in this comparative study may be based not so much on the lack of influence of air conditioning on absence because of sickness as on the satisfactory quality of the ventilation in this particular instance available to the control, non-air conditioned group. A study involving the comparison of scientific air conditioning with a wholly

inadequate method or outworn system of ventilation obviously would show more definite results favorable to air conditioning in contributing to the reduction of the incidence and duration of sickness.

WEIL'S DISEASE

REPORT OF A CASE IN A FISH WORKER

SOLOMON GLOTZER, M.D.

BROOKLYN

The following case of leptospirosis icterohaemorrhagica (Weil's disease) is being reported because of its infrequency in this country and because of its possible implications with respect to its status as a compensable occupational disease.

REPORT OF CASE

J. S., a married white man, aged 33, a fish cutter, became ill Oct. 2, 1937. His previous history was negative and his family history was negative apart from the fact that his father has an inoperable carcinoma of the rectum. The present illness began with a sudden onset of chilly sensations, fever between 103 and 104 F., aches all over the body and a slight cough. He also complained of a severe frontal headache. The headache and generalized pains persisted for four days, accompanied by chilliness and a subsiding temperature, which reached normal on the fifth day. On the second day of illness he began to complain of abdominal cramping and nausea, followed by persistent vomiting. There was marked constipation and abdominal distention. Two days later a yellow discoloration of the sclera became apparent; the urine was dark and the stools were light.

The patient was first seen on the seventh day of illness, at which time examination revealed that he was acutely ill, almost moribund, stuporous and delirious and hiccuping continually. Jaundice was intense. Scratch marks and purpuric spots were visible all over the body. The conjunctivae were markedly injected. Deep scleral icterus was present, with a moderate degree of photophobia. The pupils were equal and regular and reacted to light. The ears and nose were normal, the tongue was coated and the pharynx was moderately congested. The gums were spongy and bled easily. Extensive hemorrhagic herpes labialis was present. Examination of the heart was essentially negative except for a bradycardia of 60 per minute. Wheezes and rhonchi were heard in the right lung posteriorly. The liver was palpable one fingerbreadth below the right costal margin and was tender; the spleen was not felt. The abdomen was distended, and spasm of the right upper rectus muscle was present.

October 9, the eighth day of illness, the patient on several occasions vomited a coffee ground material. The temperature was normal at this time. Dextrose was given parenterally. Two days later he was admitted to Kings County Hospital, where he remained only one day, refusing all treatment until he was taken home. At home the patient continued to vomit for two days more, and hiccuping continued until October 15. Dextrose was continued by mouth and intravenously, with insulin subcutaneously and liver extract intramuscularly. The patient began to improve, although a secondary rise in temperature began on the fourteenth day of illness and persisted for six days. October 23, the twenty-first day of illness, there was a recurrence of marked conjunctivitis in the left eye, which subsided after a few days. The patient made a complete recovery. The results of the laboratory examination of the blood are given in the accompanying table.

The urine October 11 contained albumin 1 plus, bile 4 plus, occasional granular casts and no leucine or tyrosine. Dark-field examinations of the urine for *Leptospira* were repeatedly negative.

Intraperitoneal inoculation of guinea pigs with urine on the fourteenth day failed to produce the characteristic disease in

these animals. Blood was sent to the Public Health Service in Washington, D. C., on the twentieth and thirty-eighth days of illness respectively, and both specimens showed positive agglutination in dilutions up to 1 in 30,000.

COMMENT

It is interesting to note that this patient, when first seen, was considered to have acute yellow atrophy of the liver until examination of the blood revealed a severe azotemia. Since these observations could not be correlated with that diagnosis, Weil's disease was considered and confirmatory evidence was obtained. Further questioning of the patient elicited the fact that he worked in a fish market that was infested with rats which frequently came in contact with fish handled by him. In Aberdeen, a recent report² of the disease in forty fish workers calls attention to the great frequency of the disease in this occupation, to the extent that the diagnosis of "fish worker's disease" is often made by the patient. through the urine of infected rats has been proved by Ido² and later workers, who also examined the kidneys of rats in various parts of the world. In general it has been estimated that approximately 10 per cent of rats all over the world carry *Leptospira* in the tubules of the kidney without themselves showing symptoms, and excrete the organism in the urine. Infection in human beings usually occurs through breaks in the skin, but it has also been successfully demonstrated that, in guinea pigs, the disease may be reproduced by application of infected urine to the unbroken skin.³

Inada⁴ divided the clinical courses of the disease into three stages:

1. The febrile stage lasts six or seven days and is initiated by a chill or high fever, accompanied by intestinal disturbances, headache, cramping muscular pains particularly in the gastrocnemius muscles, conjunctivitis and prostration. The urine contains albumin and casts. Cough, sore throat and vomiting are frequent. Hemorrhagic herpes labialis may occur. Leukocytosis between 10,000 and 20,000 and azotemia are usually present. Death rarely occurs during this stage. *Leptospira* is found in the blood at this time, so that inoculation of guinea pigs with blood will induce the typical reaction. It is not, as a rule, possible to demonstrate the organisms in the urine or to find antibodies in the blood during the first stage.

2. The stage of icterus begins on the seventh or eighth day and extends for five or six days. Jaundice, hemorrhagic tendencies, prostration, and nervousness and cardiac symptoms appear. Evidences of bleeding

may be seen in all organs. Icterus occurs in only 60 per cent of cases. The liver is usually enlarged, the spleen only rarely. Azotemia becomes more marked, the blood urea ranging from 50 to 397 mg., and death from uremia may occur. The blood is free of organisms during this stage, but they can easily be found in the urine, where they may persist for forty days. The blood contains antibodies.

3. The convalescent stage begins on the thirteenth or fourteenth day. Improvement progresses with decrease in icterus and in the azotemia. Loss of hair occasionally occurs. Antibody production in the blood is complete; *Leptospira* is present in the urine, which may also contain antibodies. A secondary rise in temperature, the so-called after fever, occurs in from 28 to 40 per cent of the attacks, lasting from five to fourteen days, and may be accompanied by a secondary rise in blood urea as well.

The pathologic lesions involve primarily the liver, kidneys, skeletal muscles and capillaries. In the liver, proliferation and granular degeneration of hepatic cells, biliary stasis and periductal interstitial cellular infiltration are commonly found, with occasional areas of focal necrosis. The kidneys show swelling, granular degeneration and polyblastic invasion of the tubules and interstices, with subcapsular and interstitial hemorrhages. The skeletal muscles present punctate hemorrhages, hyaline degeneration and necrosis of the fibers. Vacuolization, loss of striations and infiltrations with cells are common. Capillary damage is indicated by minute hemorrhages, which occur in all tissues of the body.

Active immunization has been carried out in man, with an effect lasting from six to twelve months. Serum produced from horses and goats is being used therapeutically in Europe and Japan with good results if administered before the appearance of jaundice, but because of the infrequency of the disease in this country serum is not yet available here.

At the time this case was first seen, the American literature contained only twelve proved cases of Weil's disease. In the past few months, two further reports have appeared, bringing the total number of cases to twenty. This case is therefore the twenty-first to be reported in the United States and the second case found in a fish cutter. In view of the common incidence of the disease in fish workers in other countries, the question of its inclusion in the list of compensable diseases must be considered. That the disease is an occupational hazard cannot be denied, occurring as it does in all types of work in which the individual is exposed to contact with rat excreta. This question has already been raised in England. While it has not yet been declared compensable, a legal precedent was established there in 1925, when compensation was awarded for the death from Weil's disease of a coal worker, and the award upheld following an appeal (*Raeburn v. Lochgelly Iron and Coal Co., Ltd.*, 20 B. W. C. C., 637).⁵ May 17, 1935, the widow of a sewer worker in England was awarded almost \$3,000 for the death of her husband from this disease.⁶ It is therefore apparent that the disease is an occupational hazard and, as such, individuals who have contracted the disease in the course of their occupation should be awarded compensation.

In New York City, as a harbor city, with its exposure to rat infestation, it is remarkable that many more cases have not been seen. It is possible that cases have occurred and have been overlooked. Our patient tells us of another individual working in the same market who has had jaundice recently. An extensive investigation should be pursued to determine the epidemiologic potentialities of the disease in this city, with an attempt at preventive measures.

SUMMARY

1. A case of leptospirosis icterohaemorrhagica occurred in a fish worker in New York City.

2. The question of its inclusion in the list of compensable diseases has been raised and precedents have been cited from the English courts.

3. The disease should be considered in the differential diagnosis of jaundice, especially in a waterfront city such as New York where rat infestation is present.

1684 West Second Street.

IDIOSYNCRASY TO PARALDEHYDE

JACOB KOTZ, M.D.

GEORGE B. ROTH, M.D.

AND

W. A. RYON, M.D.

WASHINGTON, D. C.

During the past few years many new methods have been introduced for the relief of pain during labor, their introduction being based on the belief (in which we concur) that analgesia and anesthesia should form just as necessary and as important a part in the proper management of obstetric cases as they do in surgical cases. However, any method used for the purpose must be carefully considered as to its relative efficiency and safety for both mother and child.

We have found that paraldehyde is an efficient obstetric analgesia-amnesia producing agent with a low toxicity and that when failures have occurred they have usually been due to insufficient dosage or improper technic. Toxic effects have rarely occurred, and these have appeared when the patient had an idiosyncrasy to the drug.

In the fatal case reported in this paper there was unusual susceptibility to paraldehyde. The hypersusceptibility was regarded as being probably produced by a pathologic condition in the patient, which was not discovered until necropsy, in this instance death occurring after 31 cc. of paraldehyde was given by rectum as a single dose in the beginning of labor.

Idiosyncrasy to drugs, a condition which may be defined as a susceptibility peculiar to the individual, usually consists in a hypersusceptibility in which (1) the ordinary action or (2) inconspicuous side actions of the drugs are greatly enhanced.

Many theories have been advanced to explain each form of idiosyncrasy, but as yet not one of them can be said to be universally accepted. The one which is probably regarded by pharmacologists as the most tenable is that idiosyncrasy is due to chemico-anatomic differences in certain organs of the sensitive person which, when the structures are acted on by drugs, give rise to abnormal functions.

TOXICOLOGY OF PARALDEHYDE

Before presenting the history of our case and the conditions found at necropsy, we shall discuss briefly the toxicologic aspects of paraldehyde in order to show that the dose used in our case would not have been excessive under ordinary conditions.

Toxicologists, pharmacologists and clinicians who have used the drug for sedation other than as a soporific consider paraldehyde to be a relatively nontoxic substance.

Underhill¹ stated that the toxicity of paraldehyde is low, that poisoning is rare and that the taking of as much as 100 Gm.² has been followed by recovery.

Leschke³ searched the literature and could find only a few fatal cases of poisoning with paraldehyde. In one case, death followed the ingestion of 25 Gm., in another 52 Gm., the first apparently being the O'Brien case, in which death occurred four hours after the administration of from 22.5 to 26 cc. when the patient was delirious with typhoid. He further states that patients have recovered from as much as 150 Gm. Leschke reports a case in which recovery occurred promptly after 30 Gm. of paraldehyde, 3.2 Gm. of cyclohexenyl ethyl barbituric acid (phanodorn) and 0.4 Gm. of morphine.

Sollmann,⁴ like other pharmacologists, states that the toxicity of paraldehyde is low and that 100 Gm. produced only very prolonged sleep. He considers that as a hypnotic in severe cases of insomnia the dose may be raised to 5-15 cc.

Cushny⁵ apparently considered that the fatal poisonings reported in the literature were not altogether due to paraldehyde and hence stated that "very large quantities have been taken without fatal results and in fact without any more serious consequences than prolonged unconsciousness."

Dixon and Smart⁶ regard paraldehyde as "one of the safest of the basal hypnotics, for there is no respiratory depression." They advise 1 drachm (4 cc.) doses hourly up to 1 ounce (30 cc.), if needed, in asthma and lobar pneumonia.

Webster⁷ concludes that "the fatal dose of paraldehyde is difficult to state, as very large quantities have been taken without any serious consequences other than prolonged unconsciousness." He further cites the two cases referred to by Peterson and Haines.

Solis-Cohen and Githens⁸ regard 20 cc. as not a dangerous dose in man and in support refer to the case reported by Mackenzie in which recovery followed the ingestion of 100 cc., the sleep lasting thirty-four hours.

Meyer and Gottlieb⁹ regard paraldehyde "as a hypnotic which is really free from subsidiary actions on the functions of other organs." They advise from 4 to 6 Gm. in severe insomnia and state that from 30 to 60 Gm. has been taken without harm.

1. Underhill, F. P.: *Toxicology*, revised by Theodore Koppanyi, ed. 3, Philadelphia, P. Blakiston's Son & Co., 1936, p. 233.

2. Paraldehyde is a liquid, and since its specific gravity is 0.99 at 25 C., the dosage may be expressed either in grams or in cubic centimeters.

3. Leschke, Erich: *Clinical Toxicology*, translated by C. P. Stewart, Baltimore, William Wood & Co., 1934, p. 185.

4. Sollmann, Torald: *Manual of Pharmacology*, ed. 5, Philadelphia, W. B. Saunders Company, 1936, p. 731.

5. Cushny, A. R.: *Pharmacology and Therapeutics*, revised by C. W. Edmunds and J. A. Gunn, ed. 11, Philadelphia, Lea & Febiger, 1936, p. 363.

6. Dixon, W. E.: *Manual of Pharmacology*, revised by W. A. M. Smart, ed. 8, New York, Edward Arnold & Co., 1936, p. 44.

7. Webster, R. W.: *Legal Medicine and Toxicology*, Philadelphia, W. B. Saunders Company, 1930, p. 751.

8. Solis-Cohen, Solomon, and Githens, T. S.: *Pharmacotherapeutics*, New York, D. Appleton & Co., 1928, p. 1611.

9. Meyer, H., and Gottlieb, R.: *Experimental Pharmacology*, ed. 2, English translation by V. E. Henderson, Philadelphia, J. B. Lippincott Company, 1926, p. 105.

Brundage¹⁰ was unable to find a report of a fatal case but states that 1 drachm has produced serious symptoms and that recovery has followed a dose of 3½ ounces (105 cc.).

Heffter¹¹ states that the toxicity of paraldehyde in man is low, doses of from 10 to 12 Gm. producing only deep sleep with practically unaltered blood pressure and respiration.

Witthaus¹² does not list paraldehyde in his comprehensive work on toxicology, a remarkable fact when one considers that the drug had been employed since 1882.

Peterson¹³ and Haines found "acute poisoning with paraldehyde very rare." They cite the O'Brien case in which death occurred in a patient with typhoid after a dose of about 25 cc., and that of Mackenzie, in which recovery occurred after 104 cc.

Clinicians have for some time been using paraldehyde as a preanesthetic agent. Stewart¹⁴ used it in more than 500 cases rectally before operation, the adult dose being 30 cc. except when the patient's weight was less than 112 pounds (51 Kg.), when he used 1 drachm for each 14 pounds (6.4 Kg.) of weight. He has had no bad results.

Sourasky¹⁵ employs paraldehyde by rectum in children as a preliminary to tonsillectomy, the dose being 1 drachm for each 14 pounds of body weight.

Garrett and Gutteridge¹⁶ use paraldehyde as a basal narcotic, the rectal dose being 0.25 cc. per kilogram of body weight; that is, a man weighing 150 pounds (70 Kg.) would receive about 19 cc.

Kane and Roth¹⁷ successfully use it rectally for the relief of labor pains, the dose being 1.2 cc. for each 10 pounds (4.5 Kg.) of body weight.

Kotz and Katzman¹⁸ use it for obstetric basal analgesia, the dose being from 6 to 8 drachms (24 to 32 cc.), depending on the weight of the person and on the severity of the pains.

Rosenfield and Davidoff¹⁹ use it for obstetric analgesia, giving from 4 to 6 drachms (16 to 24 cc.) by rectum in a single dose.

Colvin and Bartholomew²⁰ also use it as a basic amnesia producing agent in obstetrics, the rectal dose being from 6 to 8 drachms.

Fitzwilliams²¹ considers it useful as a basal preanesthetic agent if the dosage is not greater than 1 drachm for each 14 pounds (1 stone) when given rectally in three equally divided doses over a forty minute period.

Henderson²² uses it for producing preanesthetic narcosis, the average dose being from 20 to 25 cc. by rectum. He has given up to 100 cc. without untoward effects.

Piker and Cohn²³ use from 11 to 15 cc. one to three times daily for sedation in the management of delirium tremens.

Mackenzie²⁴ reported a case of a married woman who took 3½ ounces of paraldehyde; consciousness returned in thirty-one hours, recovery of ability to reply to questions in forty-one hours and complete recovery soon after.

MacFall²⁵ reported a fatality in a man aged 41 who had been accustomed to taking from 1 to 2 drachms of paraldehyde daily for some months. He apparently took as much as from 2½ to 3 ounces (75 to 90 cc.) before retiring and was found dead the next morning. Autopsy revealed hyperemia of the stomach and upper portion of the intestine and congestion at the bases of the lungs. The liver, spleen and kidneys were normal.

Raimann²⁶ described two cases in each of which a 50 Gm. dose was taken without manifestation of other effects than profound depression for from fourteen to nineteen hours.

An anonymous writer²⁷ reported to the editor of the *Lancet* a fatal ending after administration of from 6 to 7 teaspoonfuls to a woman, aged 20, who was in violent delirium from typhoid for which slight hopes were being entertained of her recovery. This case is known in the literature as the O'Brien (Bridget) case. Death occurred after four hours.

Brown²⁸ reported a case of paraldehyde idiosyncrasy in a man aged 20, weighing 123 pounds (56 Kg.), in whom deep unconsciousness took place after a dose of 16 cc. The patient was rather anemic, having had a gastro-enterostomy one year previously. Recovery from the paraldehyde occurred within twenty-four hours. The prominent symptoms present were complete loss of reflexes, profound stupor, very little depression of blood pressure, rise of temperature to 102.4 F. and diminished respiratory exchange.

McDougall and Wyllie²⁹ recently reported fatal poisoning in a woman, aged 44, who died fifty hours after taking 4 ounces (120 cc.) of paraldehyde. Their patient had a mental disorder and had leaped from a window about nine months previously, producing severe cerebral concussion. An autopsy was obtained and softening of the right temporal lobe of the brain was found. The temperature on the second day rose to 105 F., indicating that infection may possibly have been a contributing factor in her death.

More³⁰ described a case in which recovery occurred after 2 ounces (60 cc.) had been taken. A man, aged 71, was admitted to the hospital Nov. 28, 1933, at 11 a. m. in a state of profound unconsciousness, the temperature being subnormal and the pulse 130. Conjunctival and pharyngeal reflexes were absent. It was later learned that the patient had taken, on November 27, 2 ounces of pure paraldehyde as a hypnotic. Under treatment with stimulants, the reflexes began to return at 7 p. m. on the day of admission and there was complete consciousness at 7 o'clock the following morning.

REPORT OF CASE

A white woman, aged 31, was first seen in September 1936, at which time her weight was 143 pounds (65 Kg.). Her body was well developed and well nourished and showed no gross

abnormalities. The eyes and ears were normal. The teeth were in good condition and the tonsils had been removed. The nose showed some mild catarrhal drainage from the sinus spaces. There was no evidence of any cervical or other glandular enlargement. The thyroid appeared normal. The lungs were normal to tactile fremitus, percussion and auscultation. The heart was normal in shape, size and position, the sounds being regular and of good intensity. No murmurs could be heard. The blood pressure was normal. There was no vascular sclerosis. The liver, gallbladder and spleen were not palpable. There was no edema of the ankles. Hemoglobin was 80 per cent (Dare) at this time. The urine was normal.

The patient's parents are still living and in fairly good health. She had whooping cough and scarlet fever during childhood, from each of which she made a complete and uneventful recovery. She is said to have had "walking typhoid" at 14 years but since she was not particularly ill at that time no blood tests were made to confirm such a diagnosis. She had a severe attack of sinusitis and bronchitis eleven years before we saw her and made a complete recovery from the bronchitis. The sinus infection improved after a short period spent in Florida. X-ray examination of the lungs showed no evidence of tuberculosis. After her return from Florida the appendix was removed, from which operation she made a normal recovery. Exploration of the gallbladder and pelvis at the time revealed no abnormalities. Periodic attacks of her sinus infection during the last eight years led to an exploration of the antrums about four years before we saw her. Little or no inconvenience was caused by the sinus infection during the last two years. She suffered from dysmenorrhea and menorrhagia for about five years previous to her marriage, but pelvic examination at that time showed a slight retroversion and a mild cervical erosion. The menstrual abnormality was relieved by endocrine therapy, and cauterization of the cervix cleared the erosion.

The patient's last normal menstrual period began Aug. 17, 1936. She experienced some nausea in September, which continued periodically until December, when she was advised to discontinue her work as a nurse.

Examination of the urine and blood pressure at this time and subsequently during the pregnancy showed both to be normal. The hemoglobin was determined in February and found to be 70 per cent. Administration of a proprietary liver preparation caused an increase to 83 per cent, at which figure it remained during the rest of the pregnancy. Calcium compounds and a vitamin D concentrate were also given throughout the pregnancy. During the last month of pregnancy edema of the ankles was present at the end of the day, but examination of the urine revealed no abnormality. Throughout the last two weeks she complained of lack of energy, with considerable exhaustion toward evening.

The appearance of edema, varying periods of nausea, lack of energy and exhaustion led to a complete examination May 15. In view of the symptoms of toxemia it was considered best to induce labor on the morning of May 20, at which time quinine and castor oil were administered. She was admitted to the hospital at 3 p. m. in active labor. At this time the blood pressure was 148 systolic, 98 diastolic and both maternal and fetal heart sounds were normal. Pelvic examination at 5:30 p. m. showed the cervix to be dilated 2.5 cm. with the head presenting in the left occipito-anterior position and partially engaged. Uterine contractions were occurring at intervals of from two to five minutes, the pains being quite severe. Having previously found that she took ether poorly and that she was sensitive to drugs (acetylsalicylic acid, morphine and codeine causing extreme nausea and depression), we decided, with the patient's consent, to administer paraldehyde as an analgesia-producing agent and accordingly 31 cc. of paraldehyde was given by rectum at 6:30. Ten minutes later the patient was in deep sleep. At 6:45 the respiratory rate suddenly increased from 20 to 40 per minute and the heart rate from 90 to 120. At 7 o'clock the patient went into coma with cyanosis, labored and rapid respiration and rapid, irregular pulse. The fetal heart rate had increased from 112 to 150 per minute. Two ampules of coramine was administered. At 7:30 the respiration

was less labored, cyanosis had disappeared and the pulse rate had slowed to 110. Her condition continued to improve somewhat except that the deep coma persisted. At this time the pupils remained fixed in partial dilatation, and the uterine contractions diminished. The fetal heart rate dropped to 140 per minute. Auscultation of the maternal heart showed no presence of valvular insufficiency.

At this time one of us (J. K.) was called in consultation and it was believed that her condition was not alarming and that she would probably sleep through the night and deliver without difficulty in the morning. At 10 o'clock her condition suddenly changed, the patient again becoming cyanotic, the respiration labored and irregular, and the pulse rapid, irregular and weak. Auscultation disclosed a loud blowing murmur over the area of the tricuspid valve, indicating failure of the right side of the heart. The blood pressure was 118 systolic, 58 diastolic. Coramine and oxygen were then administered, which relieved the cyanosis and labored respiration; the cardiac condition, however, showed no improvement. About 250 cc. of blood was then withdrawn to relieve the pressure on the right side of the heart, following which 100 cc. of 25 per cent dextrose was administered intravenously. Digifolin was also given intravenously but the pulse continued to become weaker and more irregular, and the tricuspid murmur grew louder and more harsh. Oxygen was continued, since cyanosis resulted if it was withheld. Two doses (a total of 6 mg.) of picrotoxin were given intravenously without benefit.

At this time the patient's condition appeared hopeless, as pulmonary edema was marked. A cesarean section was performed at 1:50 a. m. May 21 and a live female child was born whose condition was poor, several hours of oxygen-carbon dioxide administration being necessary for resuscitation. The patient did not require further anesthesia for the section, since coma was so deep that all reflexes were abolished. Efforts at resuscitation were continued during the operation aside from the drugs that were used to stimulate cardiac action and respiration. Intratracheal suction was employed to prevent the patient from drowning in her own secretions and to allow the entrance of oxygen. Despite all efforts, including stimulation of the sino-audicular node as recommended by Dr. A. S. Hyman, death occurred at 2:50.

NECROPSY

The significant observations made at necropsy by Dr. Oscar B. Hunter, pathologist of the Sibley Hospital, were as follows:

On section there was a considerable amount of superficial fat of a pale lemon yellow color evenly distributed. The musculature was well developed; the fibers presented a moderately coarse appearance, which was more or less normal. When the abdomen was opened the stomach was markedly ballooned with gas. The intestine contained a moderate amount of gas. The uterus presented a normal appearance of a full term uterus which had been emptied. There was definite calcification of the costal cartilages. On closer examination of the chest the anterior aspect appeared to be slightly flattened and the ribs were slightly angulated at the junction of the costal cartilages. There was no evidence of any other gross abnormality. The thoracic and abdominal viscera were normal in position and relation except for considerable dilatation of the right side of the heart. The patient was moderately dehydrated. The abdominal and thoracic tissues were moderately dry. There was a small amount of emphysematous bubbles, probably the result of artificial respiration.

The thyroid, stomach, intestine, gallbladder, pancreas, uterus and urinary bladder were normal.

The liver was soft and of a slate gray. The capsule of Glisson was smooth and glistening. The cut surface showed evidence of toxic hepatitis of long standing. There was some staining with bile. There was evidence of well defined cloudy swelling, granular degeneration and fatty infiltration. There was considerable engorgement of the sinusoids with possible focal necrosis in the region of the central veins. The connective tissue in the periportal spaces appeared to be slightly thickened. Sections through various portions of the liver revealed no evidence of thrombosis, infarcts or abscesses.

The spleen was well developed, slightly enlarged and adherent to the undersurface of the diaphragm. It showed a few superficial notchings. The capsule was slightly thickened and there was some proliferation of the malpighian corpuscles. The pulp was fairly firm and cut with slightly increased resistance. There was a mild degree of splenic tumor present.

The left kidney was normal in position and relation and the vessels and ureter entered and left in a normal manner. It was normal in size and fairly soft and there were small remnants of fetal outlines present. The kidney cut without increased resistance and the perirenal tissues contained a marked amount of fat. The cortex was swollen and presented a white and somewhat granular appearance with swelling of the columns of Bertini. The capsule stripped very easily, leaving a somewhat congested surface. The picture presented was that typical of a toxic nephrosis of some standing. There was no evidence of pyelitis or any infectious process.

The right kidney was normal in position and relation and presented more or less the same picture as the left side. There was a marked degree of hydro-ureter and hydronephrosis. It cut without increased resistance and showed considerable congestion and some edema. The pelvis was slightly dilated and the cortex was swollen with marked congestion of the interlobular vessels. There were considerable swelling of the parenchyma and cloudy swelling changes in the epithelium.

The left adrenal gland was quite soft, somewhat enlarged and quite congested. The cortex was yellow and the medulla was filled with blood. There was no evidence of adenoma or other unusual pathologic change present.

The right gland was enlarged, congested and somewhat swollen. The medulla and cortex presented much the same picture as the opposite side. There was no evidence of adenomatous changes or other specific pathologic changes.

The right side of the heart was dilated and the left side contracted. The right side collapsed when the blood was removed. The heart did not appear to be enlarged and there was a moderate amount of fluid in the pericardium. The vessels entered and left in a normal manner. There were no adhesions between the visceral and the parietal pericardium. There was a moderate amount of superficial subpericardial fat, which was normal in distribution.

The right atrium was widely dilated. The walls were stretched. The chordae tendineae and pectinate muscles were well developed but definitely stretched. There was some subendocardial fibrosis in the region of the fossa ovalis but there was no endocarditis.

The tricuspid orifice of the right ventricle was widely dilated, admitting four fingers. The tricuspid valves were well formed. There was a slight amount of thickening of the inferior margin of the leaflets. The pectinate muscles were well developed and the chordae tendineae were fine and delicate. There was no special enlargement of these structures. The columnae carnae tore with slight ease. There was definite evidence of chronic toxic myocardosis but no evidence of endocarditis or valvular disease present.

The pulmonary semilunar valves were well defined. There was slight thickening of the inferior margin but no sagging of the commissures.

The left atrium was slightly dilated. There was some subendocardial fibrosis of a patchy character, for the most part in the region of the fossa ovalis. There was no evidence of endocarditis.

The mitral valves of the left ventricle were well defined. There was slight thickening of the inferior margin of the middle leaflet and some beginning sclerosis at the bases of the leaflets. The columnae carnae were well defined and the musculature was very pale. There was a small amount of chicken fat clot. There was evidence of definite toxic myocardosis.

The semilunar valves were well defined; there was slight thickening of the inferior margin but there was no sagging of the commissures. There was also slight thickening of the bases. There were some soft, punctate, early atheromatous spots. The aortic orifice was patent.

Transverse sections through the coronary showed no evidence of coronary thrombosis or occlusion. The cut surface exuded liquid blood.

The great vessels of the neck were normal in position and relation. The aorta was soft and pliable.

There was no evidence of enlarged lymph nodes in the mediastinum, peribronchial or peritracheal regions.

The left lung was free in the pleural cavity. There was no increased amount of fluid present. There was marked congestion of the lower lobe with some petechial hemorrhages under the visceral pleura of the posterolateral aspect. The upper lobe showed compensatory emphysema. There was considerable congestion posteriorly. There was no evidence of infarcts or abscesses. Sections through the bronchial tree showed a moderate amount of frothy fluid and considerable mucus but no evidence of any obstruction of the bronchi. There was marked hypostatic congestion of the lower lobe. There was very little air in the alveoli. The upper lobe showed much the same picture posteriorly with evidence of compensatory emphysema in the anterior aspect.

The right lung was free in the pleural cavity. There was marked hypostatic congestion of the posterior aspect of the lower lobe with numerous petechial hemorrhages, probably the result of artificial respiration. The lung was quite heavy and the bronchi were filled with a considerable amount of grayish mucus and frothy fluid. The upper lobe showed considerable hypostatic congestion and edema. The lower lobe was quite dark and markedly edematous and showed pronounced hypostatic congestion. There was no evidence of infarcts, abscesses or pneumonia.

The anatomic diagnosis was:

1. Toxemia of pregnancy.

(a) Marked toxic hepatitis with cloudy swelling and fatty infiltration.

(b) Toxic nephrosis with pronounced cloudy swelling and a mild degree of hydronephrosis and hydro-ureter, particularly on the right side.

2. Mild chronic splenic tumor with toxic hyperplasia of the malpighian corpuscles.

3. Toxic adrenalitis with marked congestion.

4. Toxic myocardosis with marked dilatation of the right side of the heart.

5. Marked hypostatic congestion and edema of both lungs.

COMMENT

Under paraldehyde analgesia certain pharmacologic changes occur that are recognized as being normal. The conjunctival and corneal reflexes are absent and the pupils contract. The blood pressure drops from 10 to 30 mm. of mercury, the pulse rate being increased from 20 to 70 beats per minute. The respiratory rate is increased from 4 to 10 per minute with increased amplitude. The patient is in deep sleep.

At the time during labor when one of the authors (J. K.) was called in, consultation, our case presented this picture, although a somewhat exaggerated one. The abrupt change that occurred shortly thereafter indicated the onset of cardiac failure, from which the patient did not recover. This failure was shown at necropsy to have had a definite anatomic basis. Its onset was probably precipitated by the drug administration.

Since January 1935 we have used paraldehyde in more than 600 labor cases with very gratifying results. It is an effective analgesic which is relatively quite safe. We believe that its use should not be discontinued because of our one fatality incident to its administration, an event which might occur with any drug to which a patient is hypersusceptible. Such hypersusceptibility to paraldehyde seems to be quite rare. It is best, however, that the use of paraldehyde should be limited to hospital patients since the patient under its influence requires special care, particularly during labor.

Clinical Notes, Suggestions and New Instruments

TOPHI OF THE HEELS

FREDERICK CHRISTOPHER, M.D.

Associate Professor of Surgery, Northwestern University Medical
School; Chief Surgeon, Evanston Hospital

AND

STANLEY E. MONROE, M.D.

EVANSTON, ILL.

Gout is doubtless more prevalent than is commonly believed, yet the presence of tophi that simulate other lesions is quite rare. Out of a total of 24,766 admissions to the medical wards of the Peter Bent Brigham Hospital from 1913 to 1924 there were forty-four cases of gout.¹ In Hench's series of 100 cases from the Mayo Clinic, proved tophi were found in forty-one.

While tophi may be found in many locations, they have, according to Monroe,² a peculiar affinity for the ears. In this location he found them in 90 per cent of his cases. Tophi of the heels resembling pyogenic lesions are extremely uncommon.

REPORT OF CASE

B. H., a man aged 61, a blacksmith, came to our office in the fall of 1937 complaining of discharging lesions on the heels and pain in the heels associated with these sores. Examination of the heels revealed on each an indurated lesion about the size of a quarter (24 mm.). The lesions were slightly

Ulcerated tophi of the heels.

raised and not sharply delimited. Each was ulcerated in a small area near its center. From these small eroded centers a thick, gray, stringy material was obtained. The patient remarked about this discharge and stated that it was similar to that obtained from similar lesions on previous occasions.

Examination of this material under the microscope revealed the presence of many acicular crystals. They were variously disposed, some assuming a group arrangement not unlike the appearance of the ray fungus. When some of this material was shaken up in a test tube of water, nothing resembling sulfur bodies or cayenne pepper granules could be seen. Culture yielded no growth.

Past history told of many attacks of pain in the joints. The first attack was characterized by severe pain in the knee. The patient was then about 30 years of age. This bout of pain was of such severity as to cause him to stay in bed most of the time for three or four weeks. Nearly coincident with this attack he noticed a small gray nodule in the right ear, which had been present most of the time since. The attacks of pain in the joints recurred several times a year and varied in duration from a few days to a week or more. Most commonly the pain would start in a big toe, the ankles, knees and hands also being commonly involved, and sometimes pain was complained of under the heels. Exposure to cold is credited with bringing on many of the attacks.

The lesions on the heels appeared as pimples in 1929. They increased in size and at times were painful. They have been opened five times under the supposition that they were of pyogenic origin. Recurrences varied somewhat in location. In 1932 enlargements appeared on the hands; they have slowly progressed. The largest ones are situated adjacent to the metacarpophalangeal articulations. At times they have become swollen and tender. The patient has been a moderate user of beer, except during prohibition. He had never been on a diet until this fall. His father suffered from a similar ailment.

Smears of the discharge from lesions on the hands and heels showed acicular crystals characteristic of sodium mono-urate. Uric acid on the patient's blood showed a uric acid content of 6.31 mg. per hundred cubic centimeters.

Treatment consisted of a diet low in purines, tincture of colchicum, incision and drainage of the lesions on the heels. The response to treatment was satisfactory.

SUMMARY

In a case of gout in which there were ulcerated tophi of both heels, the lesions had five times previously been mistaken for ulcerations of pyogenic origin.

CONTINUOUS NASOPHARYNGEAL SUCTION IN THE TREATMENT OF BULBAR TYPE OF POLIOMYELITIS

O. WILLIAM ANDERSON, M.D., SEATTLE

In most epidemics of poliomyelitis a variable percentage of the patients have bulbar involvement. In some epidemics the majority of such cases are rapidly fatal, while in other outbreaks some of these patients make a satisfactory recovery if symptomatic treatment is adequate.

Usually a prominent feature in bulbar poliomyelitis is inability to swallow because of paralysis of the muscles of deglutition. As a result of this paralysis there is a constant stasis of mucous secretion in the pharynx, and the removal of this secretion is probably the most important measure in the care of the patient. When it is not possible to have a special nurse constantly with a patient who requires frequent aspiration, there is always danger of the patient drowning in his own secretions. But even in cases in which suction is frequent a grave hazard exists that small amounts of material may lead to an aspiration pneumonia, which is almost surely fatal. In the early stage of severe bulbar types the amount of secretion is often excessive, and the patients are too acutely ill and weak to lie on their sides or face down and still do well. It is at such a time that continuous removal of the buccal secretions is of paramount importance. When the secretions are allowed to gather in the pharynx, the patient becomes characteristically apprehensive and restless. To introduce a suction tube periodically aggravates seriously an already grave condition.

The following method removes these secretions continuously with little or no discomfort to the patient and has been found much more satisfactory than the customary periodic suction. A No. 10 to 16 French catheter is used, the diameter depending on the size of the patient's nasal passage. From twelve to fifteen holes are burned into the distal half inch of the catheter with a hot needle. The catheter is inserted in the nose and, with the tongue depressed, adjusted so that the tip can be seen lying at the base of the tongue. The catheter is then fastened in this position by adhesive strips at the nostril. With the foot of the bed elevated and the patient lying on his back, suction now will drain the most dependent region of the pharyngeal cavity. The perforations of the catheter are limited to the distal half inch, as already mentioned, so that no energy is wasted above the pharynx. When the openings are made on all sides of the catheter tip it becomes impossible for them all to be closed by mucous membrane, thus lessening irritation to the mucous membrane and insuring continuous suction. The catheter is now connected to a portable water suction apparatus attached to a faucet. It is important that a trap (a corked bottle with two inlets) be inserted in the line leading from the catheter to the faucet. This eliminates the danger of backflow

to the patient, which might result from a sudden change in pressure. This apparatus can be used over a considerable time, and if alternate nostrils are used every twelve to twenty-four hours no trauma to the nose or throat should result.

Several other advantages of this method have been noted. When the continuous suction is instituted, the patient loses his anxiety and promptly falls off to sleep. Those in attendance can be at ease, knowing that the secretions are being taken care of. Although for the first day or two of the acute stage the patient may have to subsist on intravenous fluids, nasal gavage feedings should be started as soon as feasible. With the nasal suction in place, the gavage feeding is given through the other nostril. If the patient regurgitates the feeding, which is always a possibility, the suction will take up the regurgitated feeding before it can be aspirated. Also the patient can be made more comfortable by being given small amounts of water by mouth. This loosens the sticky mucus that forms in the mouth. As this flows back into the throat, it too is aspirated.

This technic would seem equally useful in other conditions in which the removal of secretions gathering in the throat is a menacing problem. Patients with postdiphtheritic paralysis and those in a prolonged state of coma, such as occurs in encephalitis and head injuries, should be favorable subjects for the method described. Even patients with tetanus who cannot swallow because of spasm of the throat muscles might be helped in this way.

Special Article

THE CHEMISTRY OF VITAMIN D

CHARLES E. BILLS, PH.D.

EVANSVILLE, IND.

This article and others recently published or to be published comprise a new series on the present status of our knowledge of the vitamins. They have been prepared under the general auspices of the Council on Pharmacy and Chemistry and the Council on Foods. The opinions expressed are those of the authors and not necessarily the opinions of either council. Reprints are not available but the articles will be published later in book form.—Ed.

Studies of recent years have shown beyond a doubt that there are several chemically distinct forms of vitamin D. Nevertheless, this vitamin is still spoken of in the singular, chiefly as a convenience and because its multiple nature was not recognized for about a decade after the first form was discovered. Custom limits the application of the term vitamin D to antirachitic sterol derivatives and to the unidentified antirachitic components of fish oils and other foods which are supposed to belong to this group.

Of the several forms of vitamin D which have been recognized to date, two are known to be of prime importance in medicine. These are activated ergosterol and activated 7-dehydro-cholesterol. Other forms undoubtedly contribute to the total antirachitic effectiveness of certain agents, and it may be that the importance of some is greater than now appears. But for practical purposes, one may consider that all antirachitic medicines and foods owe their peculiar property chiefly to either or both of the two forms mentioned.

Activated ergosterol comes to the physician in several types of products which he may not always recognize as essentially identical. Ergosterol, activated by exposure to ultraviolet rays and dissolved in an oil, is viosterol in oil. Similar solutions are known abroad under several other trade names. Activated ergosterol separated from the unimportant by-products of irradiation

and crystallized comprises one form of vitamin D in the pure state. This is known to English and American chemists as calciferol. The Germans sometimes call it vitamin D₂. Since ergosterol is the principal sterol of yeast, and probably the only activatable one present, it follows that irradiated yeast owes its antirachitic action to its content of calciferol. When irradiated yeast is fed to cattle, the milk obtained is known as "metabolized" vitamin D milk. Since milk normally contains no important amount of vitamin D, the vitamin D of this special milk is essentially the calciferol which is transferred from the yeast. Thus the vitamin D of viosterol, irradiated yeast and yeast milk is one and the same; namely, calciferol.

Activated 7-dehydro-cholesterol has been identified, somewhat incompletely, as the form of vitamin D to which most other antirachitic agents owe their virtue. 7-Dehydro-cholesterol appears to be the principal activatable sterol, or provitamin, in cholesterol, the chief sterol of animal fats. Its active form thus comprises the vitamin D, which is produced in the skin, fur or feathers of animals exposed to sunlight or other sources of ultraviolet rays. For the same reason it is the form of vitamin D present in irradiated milk. It has been identified in certain fish oils and probably is the chief form, though certainly not the only form, of vitamin D that these oils contain. Since fish oils are almost universally used in poultry feeds, it appears that a substantial amount of this form of vitamin D finds its way into eggs, supplementing the supply produced by insolation of the feathers and skin of the birds. (Eggs are the only common food, except fish, naturally containing substantial amounts of vitamin D.) Fish oil concentrates are widely used to "vitaminize" milk, and the milk so treated is essentially the same as irradiated milk, but different from yeast milk, as regards the kind of vitamin D which it contains.

ACTIVATED ERGOSTEROL

Activated ergosterol is the form of vitamin D best known to the chemist.¹ Its parent substance, or provitamin, ergosterol, is the characteristic sterol of fungi. Ergosterol was first obtained from mushrooms by Bracconot in 1811. It was rediscovered by several nineteenth century chemists and was particularly studied by Tanret between 1879 and 1908. Tanret named it ergostérine because of its occurrence in ergot and its similarity to the cholestérine of Chevreul. It is now prepared from yeasts and molds, in which fungi it occurs in amounts up to 2 per cent of the dry weight, the quantity varying with the species and conditions of culture. Its origin is obscure, but seemingly it is related more closely to the metabolism of carbohydrates than to that of fats.

Ergosterol, C₂₈H₄₄OH, forms small colorless crystals usually containing some water of crystallization. The melting point varies with the water content, being 166° C. for the nearly anhydrous sterol. Polariscopic measurements show $[\alpha]_{5461}^{20} = -171^\circ$ and $[\alpha]_D^{20} = -132^\circ$ in chloroform. Three double bonds are present. The heat of combustion is 9,950 calories₂ per gram. Commercial ergosterol contains about 5 per cent of

Biol.* 4:33-349, 1935 (Symposium of July 27); *New Forms and Sources of Vitamin D*, *J. A. M. A.* 109:13-15 (Jan. 2) 1937; *Fisher, L. F.: Chemistry of Natural Products Related to Phenanthrene*, New York, Reinhold Publishing Company, 1936.

α -dihydro-ergosterol, an inert sterol which always accompanies ergosterol in fungi and which is unaltered by irradiation. Ergosterol is insoluble in water, sparingly soluble in oils and freely soluble in most of the common organic solvents.

Although ergosterol is colorless, i. e., nonabsorbing of visible light, it absorbs certain ultraviolet wavelengths as powerfully as intense dyes do in the visible parts of the spectrum. It exhibits four narrow absorption bands, with maximums at wavelengths 260, 270, 282 and 293.5 millimicrons respectively. The phenomena of activation are closely associated with these bands of absorption.

When ergosterol is exposed to ultraviolet radiations of the wavelengths which it absorbs, a transformation into vitamin D (calciferol) begins at once. However, the ergosterol, even under the most favorable conditions, never gives a 100 per cent yield of calciferol. The transformation proceeds in overlapping steps, with the formation of a series of products of which calciferol is not the last. This intricate system has been studied most extensively by Windaus and his associates at Goettingen and can be illustrated conveniently, if not too well, by the following modification of a scheme given by Setz.

At no stage during the irradiation is any one of these substances present alone. More radiant energy seems to be required to decompose calciferol than to produce it, so that when the irradiation is not unduly prolonged calciferol is the chief product. Under the best conditions it may comprise nearly 50 per cent of the total, with tachysterol and lumisterol accounting for most of the remainder. Calciferol, lumisterol and the two suprasterols have been isolated in crystalline form. Tachysterol has been separated as a crystalline 3,5-dinitro-4-methyl benzoate. Substance 248, sometimes called toxisterol, has not been obtained pure.

The reactions are purely photochemical ones, little influenced by temperature. They can take place in boiling solvents or at room temperature or at the temperature of liquid air. Nothing is added to the ergosterol molecule and nothing leaves it. There is no polymerization. The changes are merely rearrangements within the molecule. Any wavelength of light that is absorbed by ergosterol can initiate the transformations. Activation takes place more effectively in solutions than in solid masses. Solutions that are agitated during irradiation are activated better than those which remain quiet. The presence of more than traces of air is detrimental. There is a specific solvent effect, in accordance with which various solvents which are satisfactory as to transparency and nonreactiveness are nevertheless unequally effective in promoting the activation of ergosterol dissolved in them.

To comprehend the molecular changes that occur when ergosterol and other D provitamins are irradiated, one must examine the structural formulas of these sterols. The accompanying figures and discussion are necessarily limited, though the field of sterol chemistry is wide.¹

Figure 1 shows the accepted sterol ring structure, with a side chain as in ergosterol. The ring system is a phenanthrene-cyclopentane complex, the same as in many of the sex hormones. It is, incidentally, one of the biggest aromatic nuclei with which the animal body has to deal. Hydrocarbons of this type are formed when sterols are subjected to dehydrogenation with suitable reagents, such as selenium.

The prototype of all sterols is cholesterol, shown in figure 2. Ergosterol (fig. 3) differs from cholesterol in its side chain, which contains a double bond at C₂₂ and a methyl group at C₂₄, and in its nucleus, which contains two double bonds instead of one. In hydroaromatic structures as complicated as the sterols, the possibilities of molecular rearrangement are great, yet

Fig. 1.—The sterol ring structure. Side chain shown as in ergosterol.

most of those which are known to occur are *cis-trans* changes at C₃, C₅, C₉ or C₁₀. The spatial geometry of these changes is not perfectly understood, and structural formulas as ordinarily written do not show them.²

In all naturally occurring sterols (but not in the sterol derivatives called vitamin D), the hydroxyl group at C₃ is *cis* to the methyl group at C₁₀. It is a rule that this configuration exists when a sterol is capable of forming a precipitate with digitonin—the familiar analytical reaction by means of which cholesterol and ergosterol are determined. Since none of the irradiation products of ergosterol reacts with digitonin, it is assumed that in them the OH at C₃ is *trans* to the CH₃ at C₁₀. This rearrangement is probably the first change brought about by the activating rays and perhaps the only difference between ergosterol and lumisterol. Except for this difference, and the possibility of another steric difference at C₉, ergosterol and lumisterol are identical. Figure 3 is the formula for each of them, and also for pyro-calciferol and iso-pyro-calciferol, two sterols which result from heating calciferol. All four differ from one another only as *cis-trans* isomers, indistinguishable in ordinary, two-dimensional formulas.²

The change from lumisterol to tachysterol involves a deeper alteration of the molecule. The structural formula of tachysterol is not known with certainty, but since tachysterol and calciferol yield the same dihydro

Fig. 2.—Cholesterol.

Fig. 3.—Ergosterol, lumisterol, pyro-calciferol and iso-pyro-calciferol.

derivative³ the two must have the same carbon skeleton. Tachysterol, like calciferol which follows it, has four double bonds instead of the three exhibited by lumisterol and ergosterol. The fourth double bond arises by a rupture of ring B. Tachysterol was given

its name in recognition of the speed with which it enters certain reactions. A tentative structural formula, suggested by Lettré, is given in figure 4.

In the change from tachysterol to calciferol, the molecule returns to a relatively stable form. The formula may be written either as in figure 5, which emphasizes the relation of calciferol to the sterols (steroid formula), or as in figure 6, which emphasizes the broken

Fig. 4.—Tachysterol (a tentative formula).

Fig. 5.—Calciferol (vitamin D₂). Usual, or steroid, formula.

ring B (stilbenoid formula). Different as the two formulas may look at first glance, they are actually the same. Figure 5 is the conventional representation, but figure 6 shows more clearly that the vitamin is not a sterol in the strictest sense, albeit a sterol derivative.

Irradiation of calciferol (i. e., overirradiation of ergosterol) occasions the formation of substance 248 and the two suprasterols. Substance 248 derives its name from its single intense absorption band, the maximum of which is at wavelength 248 millimicrons and is thus outstandingly different from the longer wavelength maximums of the irradiation products preceding it. Sometimes it is called toxisterol, in recognition of the toxic-calcifying properties which it exhibits out of all proportion to its antirachitic activity, if any. Toxisterol is formed most readily when alcohol is the solvent in which the overirradiation is conducted. When ether is the solvent it may not appear in detectable amounts. If it is formed at all it must immediately pass over to the suprasterols, into which it also passes when irradiation of alcoholic solutions is sufficiently prolonged. The substance has never been isolated, so practically nothing is known about it chemically.

The toxic properties peculiar to one particular brand of irradiated ergosterol solution were the subject of numerous reports in the medical literature of 1928 to 1930. The German manufacturer of the offending product had obtained two patents, one British⁴ and the other American,⁵ the specifications of which are most revealing. They call for the irradiation of ergosterol

Fig. 6.—Calciferol, stilbenoid formula.

to be continued just until the absorption spectrum of what is now recognized as toxisterol attains its maximum! The mistake was clearly the result of assuming,

in the absence of proper bio-assays, that the spectrographically most conspicuous irradiation product was the vitamin. That this is not so was known, even in 1928, from a study⁶ conducted in this laboratory in which substance 248 was recognized as a decomposition product of the vitamin.

Whatever may be the number of double bonds in toxisterol, it appears that in suprasterol I the number is reduced from four to three. This results from a

closure of the break in ring B, but the closure which in this case is brought about by prolonged exposure to ultraviolet rays is different from that which is produced when the two pyro-calciferols are made from calciferol by the action of heat. In suprasterol I the restored ring B may be five sided rather than six sided (fig. 7). Less is known of suprasterol II; the distinction I or II is arbitrary and does not indicate sequence of formation. Even the number of double bonds, to say nothing of their position, is unknown.⁷

In the accompanying table is a summary of properties of the irradiation products of ergosterol, including also the properties of the pyro-calciferols.

ACTIVATED 7-DEHYDRO-CHOLESTEROL

For several years after the activatability of ergosterol was known there prevailed a hypothesis, disproved by Waddell⁷ in 1934, that traces of ergosterol comprised the provitamin to which the common sterols of animals and plants owed their activatability. This concept was based on the fact that the common sterols usually show the characteristic absorption spectrum of ergosterol more or less in proportion to their activatability. The possibility had been overlooked that there might exist other D provitamins having the same absorption spectrum as ergosterol.

On theoretical grounds it appeared that 7-dehydro-cholesterol might be such a provitamin. This compound was prepared in the following semisynthesis by Win-

Fig. 7.—Suprasterol I (a tentative formula).

Fig. 8.—7-Dehydro-cholesterol.

daus, Lettré and Schenck⁸ and was found to be highly activatable. Cholesteryl acetate was oxidized by chromic acid to 7-keto-cholesteryl acetate. This was reduced by aluminum isopropylate to 7-hydroxy-cholesterol, the di-benzoate of which, when strongly heated, gave the mono-benzoate of 7-dehydro-cholesterol. From this the free sterol (fig. 8) was obtained by saponification.

In at least one instance, 7-dehydro-cholesterol has been chemically identified as the provitamin D of ordinary cholesterol. Windaus and Bock⁹ isolated it from the sterol of hog skin. Boer, Reerink, van Wijk and van Niekerk¹⁰ also isolated it from a crude cholesterol of unstated origin. However, ergosterol itself sometimes occurs in animal cholesterol, as was shown by Windaus and Stange¹¹ in eggs. This is probably an exceptional instance, associated with the fact that hens, unlike the mammals that have been investigated, absorb ergosterol from their food. The presence of ergosterol in eggs therefore seems casual, especially since the vitamin D of eggs is ordinarily not the ergosterol vitamin D, a form which, for birds, is relatively ineffective

in comparison with the vitamin D from 7-dehydro-cholesterol.¹² The chief evidence that 7-dehydro-cholesterol is the usual provitamin D of cholesterol is found in experiments with rats and chickens which show, in a word, that the vitamin D produced by irradiating the cholesterol from butter, brains, fish oils and other sources has the biologic properties of activated 7-dehydro-cholesterol rather than those of activated ergosterol.

Fig. 9.—Activated 7-dehydro-cholesterol (vitamin D₃).

Activated 7-dehydro-cholesterol, prepared by irradiating the synthetic provitamin, has recently been obtained in crystalline form by Schenck.¹³ The crystalline vitamin has not yet been obtained from natural sources, but crystalline esters of it have been obtained from tuna¹⁴ liver (species not specified) and halibut¹⁵ liver oils. These esters resemble the corresponding esters of the artificially made vitamin, but the fish oil vitamin liberated from the esters could not be crystallized.

Physicochemical Properties of the Irradiation Products of Ergosterol and of the Thermal Decomposition Products of Calciferol

Substance	Melting Point, Degrees C.	Digitonin Reaction	Position* of Absorption Maximums, Millimicrons	Double Bonds	Specific Rotation, [α] _D		Temperature, Degrees C.
					Rotation, Degrees	Solvent	
	166	Positive	260, 270, 282, 293.5	3	−132	Chloroform	20

	115	Partial	265, 280, 294	3	+332	Chloroform	20

* The position of the most important band is indicated by the use of bold face type.

This fact, and also the fact that the potency appears to be significantly less than that of the crystalline vitamin, suggest that the vitamin preparations from fish oils were not pure, even though the evidence is good that they consisted chiefly of activated 7-dehydro-cholesterol.

The formula of activated 7-dehydro-cholesterol is shown in figure 9, from which its close relationship to calciferol (fig. 5) is evident. It is, in fact, a demethyl-dihydro-calciferol, just as its provitamin (fig. 8) is a demethyl-dihydro-ergosterol. Its absorption spectrum resembles that of calciferol, just as the absorption spectrum of its provitamin resembles that of ergosterol. Its antirachitic effectiveness is the same as that of calciferol for rats but many times greater for chickens.

In the German literature, activated 7-dehydro-cholesterol is called vitamin D₃. Calciferol is vitamin D₂. But there is no vitamin D₁, this term having been preempted for a lumisterol-calciferol mixture originally mistaken for the pure vitamin. Vitamin D₄ is the name applied to activated 22-dihydro-ergosterol, to be described.

rachitic for rats than the other two D vitamins, and for chickens its activity, per rat unit, is intermediate.¹⁸

22-Dihydro-calciferol, or vitamin D₄, has not been isolated from natural sources. Possibly its provitamin occurs in the phytosterols of the plant kingdom. If so, this form of vitamin D is produced when vegetable products are irradiated, and it may come to the interest of the physician in such forms as irradiated rolled oats and breakfast foods.

Fig. 10.—22-Dihydro-ergosterol.

Fig. 11.—Activated 22-dihydro-ergosterol (22-dihydro-calciferol, or vitamin D₄).

By reactions analogous to those used in converting cholesterol into 7-dehydro-cholesterol, Wunderlich¹⁹ has converted sitosterol (fig. 12) into 7-dehydro-sitosterol (fig. 13). This has the "ergosterol" absorption bands and can be activated to a vitamin, supposedly of the formula shown in figure 14. This vitamin, differing by a side chain ethyl group from activated 7-dehydro-

cholesterol, appears to be much less antirachitic than the latter for rats. However, the two have not been compared in the pure state. Like vitamin D₂, this form of vitamin D may be produced when vegetable products are irradiated.

Again, by the same reactions, Linsert²⁰ has converted stigmasterol (fig. 15) into 7-dehydro-stigmasterol (fig. 16), which exhibits an absorption spectrum "very much like" that of ergosterol. Chemically, it differs from ergosterol only in that it has an ethyl group at C₂₄.

Fig. 12.—Sitosterol.

Fig. 13.—7-Dehydro-sitosterol.

instead of a methyl group. When irradiated, it most surprisingly does not become antirachitic, or at most very slightly so. This anomalous behavior, if true, is an instance of the fine specificity with which small molecular differences influence the physiologic properties of substances. It would be a matter of considerable theoretical interest to ascertain whether the reported failure of the expected new vitamin D is evident when the irradiated substance is given intravenously as well as when given by mouth.

Years ago, I observed that treatment of cholesterol with fullers' earth resulted in a slight activation. Yoder²¹ has traced this reaction to the formation of cholesterolene, the probable formula of which (fig. 17) has recently been given by Stavely and Bergmann.²² Cholesterolene sulfonic acid and its salts are definitely, though not powerfully, antirachitic for rats, and it has been reported that their effectiveness for chicks, per rat unit, is somewhat greater than that of cod liver oil. It will be observed that cholesterolene differs greatly in structure from the other forms of vitamin D.

Up to this point I have considered five forms of vitamin D, the chemical structures of which are well understood. Four of these are the active irradiation products of ergosterol, 7-dehydro-cholesterol, 22-dihydro-ergosterol and 7-dehydro-sitosterol respectively. The fifth, cholesterolene sulfonic acid, requires no irradiation. There are still other forms, as yet not understood chemically, but which deserve mention in passing.

Fig. 14.—Activated 7-dehydro-sitosterol.

Fig. 15.—Stigmasterol.

Sixth: McDonald has found that by the irradiation of 7-hydroxy-cholesterol (or an impurity associated therewith) a slight antirachitic potency is developed. This may or may not be the same kind of vitamin D as that which is developed when cholesterol, freed from its normal provitamin and subsequently heated to produce a new provitamin, is irradiated.¹

Seventh: Cholesterol freed from its normal provitamin but not heated to produce the new one gives on irradiation a vitamin D which is less effective for chickens, per rat unit than the vitamin D which is formed by irradiating either unpurified cholesterol or heat-treated purified cholesterol.²³

Eighth: McDonald and I found that ergosterol, when suitably treated with nitrites, gives an active product of low potency. It is believed to be different from the ordinary forms of vitamin D which are destroyed by nitrites.¹

Ninth: Weinhouse and Kharasch²⁴ have produced a form of vitamin D by irradiating the heated reaction product of 7-keto-cholesteryl acetate and isobutylmagnesium bromide.

Tenth: Windaus and Trautmann,¹⁷ in a footnote, mention "other provitamins, e. g., 22,23-oxido-ergosterol, which, however, are only feebly active after irradiation."

To correct a somewhat prevalent wrong impression, it may be pointed out that the kind of vitamin D which is produced by irradiating a given provitamin is not determined or even influenced by the conditions of irradiation. For example, from ergosterol, calciferol is the only kind of vitamin D produced. Whether long wavelength, short wavelength or mixed wavelength radiation is employed, as in different commercial processes, the end product is the same as regards the vita-

Fig. 16.—7-Dehydro-stigmasterol.

Fig. 17.—Cholesterolene.

min. The only differences are in the relative amounts of by-products, chiefly in the lumisterol and tachysterol, which are unimportant physiologically in the amounts present. Avoidance of the undesirable toxisterol is a matter of choice of solvent and duration of exposure.¹ Processes in which electron bombardment is substituted for ultraviolet irradiation produce the same kind of vitamin D, although they do so inefficiently because of extensive decomposition.²⁵

Little has been said here with regard to the D vitamins of fish oils, which comprise by far the largest source of antirachitic medication for both man and animals. Demethyl-dihydro-calciferol (vitamin D₃), as already stated, appears to be the principal form of vitamin D present. However, the work of Bills, Mas-sengale, Imboden and Hall¹² shows that more than one kind of vitamin D occurs in the liver oils of various species of fish. Even cod liver oil may contain a multiplicity of forms. Progress in separating and identifying the natural vitamins D may be expected from studies now under way in which the molecular distillation technic of Hickman²⁶ is applied to liver oils.

SUMMARY

The properties of vitamin D are exhibited by at least ten different sterol derivatives. Five of these are well understood chemically and five are distinguished by

fragmentary chemical and physiologic differences. The two that are of prime importance are the activation products of ergosterol and 7-dehydro-cholesterol respectively. A few of the others may have some practical significance, though most of them are merely of theoretical interest, illustrating the concept of the multiple nature of vitamin D.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT. HOWARD A. CARTER, Secretary.

OMEGA ELECTROLYSIS MACHINE NOT ACCEPTABLE

Manufacturer: Omega Electrolysis Company, 535 Fifth Avenue, New York.

The Omega Electrolysis apparatus, as the name implies, is designed to remove superfluous hair. It comes in both a portable and a cabinet model. Housed in a custom-built case, the portable unit weighs approximately ten pounds; the larger unit comes in a metal or wood cabinet as desired. Both models contain batteries as a source of energy.

Equipment includes shockproof holders for platinum needles and a support for them, so that a number of depilations may be performed at the same time. A metal cup is used as the indifferent electrode and is attached to the positive pole for operation. The portable model contains outlets for from six to eight needles; the larger models contain from eight to ten. One control lever (attached to the rheostat) and a meter are on the instrument panel. A dry battery, supplying approximately 9.2 volts, supplies current to operate the unit. The construction, underneath the instrument panel, is extremely simple, composed of a switch, meter, rheostat and terminals for the needles. Two bottles, one containing antiseptic and the other a sterilizing fluid, are part of the equipment. Neither of these preparations has been considered or accepted by the Council on Pharmacy and Chemistry.

Treatment procedure consists of inserting the needle into a hair follicle, following the direction of the hair, and applying sufficient current to dissolve the papilla, thus destroying the nutritive source at the root of the hair. This process takes from two to three minutes, depending on the strength of the current as well as the type of hair follicle particular to the individual.

A reliable investigator was appointed by the Council to report on the unit. He tried it out clinically. Although it worked satisfactorily when new, a question was raised as to its durability. A casual inspection of the makeup of the apparatus was convincing proof of the fragility of construction.

Even if it were made satisfactory mechanically, it still could not be acceptable because of the type of advertising matter circulated with it. This extols the merits of electrolysis, making the procedure appear to be very simple whereas in reality it should be attempted only by competent, trained physicians or specialists working under the supervision of a physician. The inexperienced operator is not apt to apply aseptic technic. As a consequence, infection and serious disfigurement may result.

The advertising matter is written to appeal to the beauty shop operator and the untrained technician. An "Omega Method" for becoming an expert "electrologist" is advertised, outlining the type of instruction given and offering a certificate to any one completing the course, either by home study or at the dealer's office. No evidence was presented to indicate that the instruction was given by qualified physicians trained in this branch of medicine.

The Council on Physical Therapy voted not to include the Omega Electrolysis machine in its list of accepted devices on the basis of an advertising policy detrimental to the public welfare.

Council on Pharmacy and Chemistry

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary.

AMINOACETIC ACID (See New and Nonofficial Remedies, 1938, p. 51).

Aminoacetic Acid-Mallinckrodt.—A brand of aminoacetic acid-N. N. R.

Manufactured by Mallinckrodt Chemical Works, St. Louis.

ANAEROBIC ANTITOXIN (See New and Nonofficial Remedies, 1938, p. 383).

Mulford Biological Laboratories, Sharp & Dohme, Philadelphia and Baltimore.

Gas-Gangrene Antitoxin (Combined) Concentrated.—An antitoxic serum prepared by immunizing horses with the toxins of *B. perfringens* (*Clostridium welchii*) and *Vibrio septique* (*Cl. oedematis maligni*). After the desired potency is obtained, the horses are bled aseptically, the plasma is separated, and the antitoxin concentrated by a method which is similar to that used for concentrated diphtheria and tetanus antitoxin. The unitage is determined according to the method prescribed by the National Institute of Health. Marketed in packages of one syringe containing 10,000 units each of perfringens antitoxin and *Vibrio septique* antitoxin.

Dosage.—Therapeutic: The initial injection of the contents of one syringe preferably by the intravenous route, followed by the intramuscular or intravenous administration of repeated doses as indicated by the condition and symptoms of the patient.

Gas-Gangrene Antitoxin (Combined) Unconcentrated.—An antitoxic serum prepared by immunizing horses with the toxins of *B. perfringens* (*Cl. welchii*) and *Vibrio septique* (*Cl. oedematis maligni*). After the desired potency is obtained the horses are bled, and the serum is separated and prepared in a manner similar to other unconcentrated antibacterial and antitoxic serums. The unitage is determined according to the method prescribed by the National Institute of Health. Marketed in bottles containing 10,000 units each of perfringens antitoxin and *Vibrio septique* antitoxin.

Dosage.—Therapeutic: The initial injection of the contents of one bottle, preferably by the intravenous route, followed by the intramuscular or intravenous administration of repeated doses as indicated by the condition and symptoms of the patient.

POLLEN EXTRACTS-ABBOTT (See New and Nonofficial Remedies, 1938, p. 48).

The following dosage form has been accepted:

Mixed Grass Pollen Extract, Decimal Dilution Set: A mixture of equal parts of June grass, timothy, orchard grass, redtop, and sweet vernal grass pollen extracts, marketed in packages of five vials containing respectively, 5 cc. of a 1:100,000 dilution (10 pollen units per cubic centimeter), 5 cc. of a 1:10,000 dilution (100 pollen units per cubic centimeter), 5 cc. of a 1:1,000 dilution (1,000 pollen units per cubic centimeter), 5 cc. of a 1:100 dilution (10,000 pollen units per cubic centimeter), and 0.5 cc. of a 3 per cent dilution (30,000 pollen units per cubic centimeter).

RHUS TOX. ANTIGEN-STRICKLER (See New and Nonofficial Remedies, 1938, p. 369).

The Mulford Colloidal Laboratories, Philadelphia.

Rhus Tox. Antigen-Strickler: Also marketed in packages of two 1 cc. syringes.

RHUS VENENATA ANTIGEN-STRICKLER (See New and Nonofficial Remedies, 1938, p. 369).

The Mulford Colloidal Laboratories, Philadelphia.

Rhus Venenata Antigen-Strickler: Also marketed in packages of two 1 cc. syringes.

VIOSTEROL IN OIL (See New and Nonofficial Remedies, 1938, p. 482).

Viosterol (A. R. P. I. Process) in Oil-Hospital Liquids, Inc.—A brand of viosterol in oil-N. N. R.

Manufactured by the American Research Products, Inc., a subsidiary of General Mills, Inc., Minneapolis, under license agreement with E. I. du Pont de Nemours & Co. U. S. patent applied for. (Hospital Liquids, Inc., distributor.)

Viosterol (A. R. P. I. Process) in oil (Hospital Liquids, Inc.) is prepared by the activation of purified ergosterol by low velocity electrons. The activated ergosterol is refined and dissolved in vegetable oil. The final product, when assayed according to U. S. P. method, has not less than the vitamin D potency of viosterol in oil-N. N. R.

DEXTROSE (See New and Nonofficial Remedies, 1938, p. 162).

Wm. S. Merrell Company, Cincinnati.

The following dosage form has been accepted:

Ampoules Solution Dextrose 50%, 100 cc.: Each ampule contains 100 cc. of a sterile aqueous solution containing 50 Gm. of dextrose-U. S. P.

TISSUE PREPAREDNESS FOR THE PRODUCTION OF SPECIFIC ANTIBODIES

In the past it has been presumed by some immunologists that the fixed tissues are autonomous in production of specific antibodies. Recent investigations indicate, however, that antibody production is further dependent on unknown hormonal or neurologic integrations.

Scores of unsuccessful attempts have been made to produce specific antibodies by adding antigens to tissue cultures. In spite of the few allegedly successful results the general consensus is that explants from the spleen, lungs and bone marrow of embryonic or adult laboratory animals are incapable of synthesizing precipitins, agglutinins, hemolysins, antitoxins or complement-deviating antibodies.¹

Admitting these failures, recent investigators have modified the *in vitro* technic. They have injected antigens intravenously into experimental animals and after arbitrary intervals made tissue cultures from antigen-laden spleen or bone marrow. Landsteiner and Parker² of the Rockefeller Institute, for example, found that antigen-laden splenic fragments taken from rabbits injected from one to twenty-four hours previously with guinea pig erythrocytes failed to produce specific antibodies. If, however, an interval of from two to three days was allowed between the intravenous injection and the removal of the antigen-laden splenic fragment, agglutinins of relatively high titer were synthesized or secreted by the resulting tissue culture. Dr. Tsai³ of the Microbiological Institute, Imperial University, Kyoto, reports a similar synthesis or secretion of diphtheria antitoxin *in vitro* by antigen-laden splenic tissues, removed from forty-eight hours to five days after intravenous injection of diphtheria toxin or toxoid.

Observations of this type seem to indicate that the production of antibodies by fixed tissues depends on certain wholly unknown preparatory reactions in the

intact animal. These reactions are usually not completed until the second or third day after the intravenous injection of antigen. Landsteiner and Parker found that splenic fragments taken from animals given injections twenty-four hours previously, when cultivated in fully prepared serum, *i. e.*, serum taken from control rabbits given injections three days previously, also fail to produce antibodies. From this they argue that serologic preparedness alone is insufficient; the splenic tissues themselves apparently must undergo a supplementary *in vivo* preparation.

These investigations seem to signify that production of specific antibodies can no longer be considered an autonomous function of fixed tissue cells but is rather a function of the body as a whole, working through local tissue preparedness for synthesis of antibodies. No one has yet attempted to formulate a theory as to the nature of this tissue preparedness, but knowledge of the nutritional, hormonal or neurologic factors involved may have important clinical applications.

EPIDEMICS IN ENGLISH SCHOOLS

The great majority of English boys and girls receive their education in nonresidential schools; for this reason the maintenance of health in such schools is of preponderating practical importance. Twenty-one boys' schools and ten girls' schools agreed to participate in a statistical inquiry,¹ and investigation was begun in the Lent term of 1930. Although all large boarding schools cooperating are organized on the "house" system, the suggested uniformity of organization and environmental conditions does not actually exist. Great differences in house organization are found, especially in the boys' schools, while standards of accommodation vary not only between different schools but between different houses in the same school. These variations complicate epidemiologic questions to the extent that renders comparative discussion extremely difficult; nevertheless certain of the observations are definitely worth recording. The extensive study of nasopharyngeal infections and sore throats for example leads to the practical conclusion that, although an unusual incidence of sore throats should authorize vigilance with regard to the possible appearance of scarlet fever, otitis media or rheumatism, a low incidence of such infections is no guaranty of freedom from risk from these more serious diseases.

Knowing that the environmental conditions in girls' schools differ considerably from those of most boys' schools, the data from each were kept separately. It soon became obvious that the two populations, male and female, were being subjected to different influences which were reflected in the attack rates of nasopharyngeal infection. Such infections were much higher among the girls than among the boys, but, since the

2. Parker, R. C.: *Science* 65: 292 (March 19) 1937.

3. Tsai, L. H.: *J. Immunol.* 33: 471 (Dec.) 1937.

1. *Epidemics in Schools*, Privy Council Medical Research Council Special Report Series, No. 227, London, 1938.

records were limited to sickness causing at least one day's absence from school, two alternative explanations were possible: the girls may have been actually more susceptible to such infections or they may have been subjected to a stricter surveillance and on that account more likely to be kept out of school. It is perhaps not surprising that when the "common cold" and influenza were made into a single group of "nasopharyngeal infections" this group accounted for 53 per cent of all the time lost on this account among girls and for 43 per cent among boys. While it is possible that active methods of immunization against influenza may serve to cut the time lost from this cause, no promising method of immunization against colds has as yet become available.

Another interesting aspect of the report was that dealing with the relation between chickenpox and herpes zoster. Investigation showed that in eighteen out of twenty cases when zoster preceded chickenpox the first patient with chickenpox might, from the point of view of time, have been infected by a patient with zoster. When further examined, there seemed to be a suggestion that when zoster was the infecting agent the resulting attack rate of chickenpox was almost always small, whereas when chickenpox appeared first there was a greater chance of the disease spreading, although exceptions to both rules occurred. Evidence was not found, however, that chickenpox conferred immunity against zoster. The data on influenza showed (with the exception of one school) that there was no evidence of an actively acquired immunity lasting for as long as one year. In fact, in the pairs of epidemics analyzed, those who had influenza one year were more rather than less likely to contract it the following year in comparison with those who had escaped the first epidemic.

The examination of the record cards of the entire group at the beginning of the inquiry in 1930 showed that just over half the boys and just under half the girls had had their tonsils removed. These proportions rose slowly until, at the end of 1934, they had increased by almost 6 and 7 per cent respectively. The incidence of nasopharyngeal infections was studied in relation to this procedure. When the preoperative and postoperative history of the group of 364 boys whose tonsils were removed during school life were studied it was found that, whereas before tonsillectomy the attack rates from nasopharyngeal infection and time lost were appreciably higher than the average, after tonsillectomy these rates approximated closely the expected. Evidence was not obtained, however, that tonsillectomy resulted in a diminution in incidence of nasopharyngeal infections. The report concludes: "Though realizing the value of the operation in carefully selected cases, we have grave doubts as to whether the majority of tonsillectomies performed today are the result of true discrimination, rather than of routine ritual."

Although many other important epidemiologic problems are discussed, the report is careful to state that its main purpose is to formulate the epidemiologic problems needing study and solution rather than to draw extensive practical conclusions from a study which they still consider of a preliminary nature. Nevertheless the fund of information assembled can be considered a fundamental contribution to a subject of immense potential practical importance.

VITAMIN C AND COMPLEMENT

The factors governing the amount of complement in the blood of animals, especially the guinea pig, have long been obscure. Observations have been reported relating variations in complement to seasonal changes, disease and diet. Among these the last has received increasing attention; it has been suggested that vitamin C intake is of major importance in determining the complement titer. The evidence on this point, however, has not been conclusive. Recently Ecker and his associates¹ at Western Reserve University have reported extensive studies on the relation of vitamin C to complement. Many of the investigations on complement titer have been complicated by the difficulty of determining accurately the amount of this agent in a given sample of blood.^{1a} In titrating complement, washed sheep erythrocytes and heated antiserum (obtained by injecting rabbits with sheep cells) are mixed, and the minimal amount of unheated guinea pig serum which must be added in order to cause complete hemolysis is determined. However, as several authors have indicated, it is impossible by this method to determine with any great degree of accuracy the amount of complement in guinea pig serum. Accordingly, Ecker and his collaborators used two methods of titration for their samples, one proposed by Koopman and Falker,² in which the minimal amount of serum necessary to initiate hemolysis is determined, and the other suggested by Brooks,³ in which the amount of serum necessary to hemolyze 50 per cent of the erythrocytes is estimated. The amount of vitamin C in the blood was determined chemically.

Using these procedures, the Cleveland investigators showed a definite correlation between the amount of vitamin C in guinea pig serum and the complement titer.^{1a} Animals on a scorbutigenic diet showed a diminution in amount of complement parallel with the decrease in vitamin C content of the serum. The

3. Brooks, S. C.: Precise Titration of Complement, *J. M. Research* **41**: 399 (May) 1920.

feeding of ascorbic acid to scorbutic animals increased the complement titer. Similarly, the addition of crystalline vitamin C to serums deficient in complement increased the titer to normal and also rendered these serums more stable. The optimum level of vitamin C was found to be about 1 mg. in 100 cc. of serum. When the content of ascorbic acid was increased beyond this level no further effect developed on the complement activity. Ascorbic acid itself is not identical with complement, though it is essential to the activity of this factor in immunity. As Ecker and his collaborators found, crystalline vitamin C "will not hemolyze sensitized cells either by itself or in the presence of inactivated serum."^{1a}

Complement that has been inactivated by certain procedures, such as prolonged shaking or treatment with ammonia, cannot be regenerated by addition of vitamin C.^{1c} However, denaturation of complement by yeast or inactivation by aeration^{1c} or by the addition of minute amounts of iodine, hydrogen peroxide or other substances^{1d} may be reversed with ascorbic acid.

The mechanism whereby vitamin C affects complement function appears to be related to its reducing capacity. Glutathione, like ascorbic acid a physiologic reductant, appears also to be implicated in the reducing system affecting the complement activity of blood.^{1e} Further, the Western Reserve investigators have found that inorganic reducing agents, such as hydrogen sulfide and sodium hydrosulfite ($\text{Na}_2\text{S}_2\text{O}_4$), can activate complement.^{1d}

The fundamental work of Ecker and his collaborators has thus added an important chapter to knowledge of the biochemical basis of immune reactions.

Current Comment

PNEUMOCOCCUS POLYSACCHARIDE IN URINE

Urinary excretion of the specific capsular substances formed by pneumococci is of little or no diagnostic value, owing to the inconstant excretion of this substance during the early stages of lobar pneumonia. Cruickshank¹ of the University and Royal Infirmary, Glasgow, Scotland, however, believes that detection of the type-specific polysaccharide in the urine is a valuable prognostic index, the mortality among patients with "pneumococcosuria" being twenty times greater than that of pneumonia patients whose urine remains free from this polysaccharide during the course of the disease. Cruickshank's conclusions were drawn from his study of about 200 patients with pneumococcal infections, 184 of whom were suffering from lobar pneumonia. Type polysaccharides were estimated quantitatively in the urines of these patients by means of high titer type-specific antisera. The serum used in most of his tests was capable of detecting homologous pneumococcus polysaccharide in dilutions as high as 1:5,000,000. The daily output of type pneumococcosuria

in some of his cases was as high as from 3 to 30 mg. The mortality of his patients with type I or II polysaccharide excretion was about 40 per cent. The mortality among lobar pneumonia patients with polysaccharide-free urines was only 2 per cent. In a certain number of cases with delayed resolution the specific polysaccharide continued to be excreted for from twenty-five to forty days during convalescence, presumably as a result of the gradual dissociation of the pneumococcus hapten from its combination with humoral or intracellular antibodies. Whether or not urinary excretion of pneumococcus specific substances is a physiologic process or a pathologic process due to toxic injury to the kidney epithelium has not been determined. If, however, pneumococcosuria is a reliable prognostic index as Cruickshank believes, it may be a valuable guide to a rational therapy in lobar pneumonia. Cruickshank suggests that specific serum therapy should be limited to patients with positive pneumococcus polysaccharide in the urine.

EFFECT OF CHILDHOOD ILLNESSES ON GROWTH

The opinion prevails that children who are frequently ill are "stunted" in their growth and unlikely to develop normally. The possible effects of recurrent illnesses on the physical growth of a group of normal boys and girls has now been investigated by Hardy.¹ The group was representative in socio-economic status, national origins and general intelligence of pupils in regular attendance in the public schools of an industrial urban community in the Middle West. The criteria of selection were principally dependent on the willingness of the parents to cooperate. Cumulative health histories were built up from information obtained in the home and records on file in the school office. Yearly interviews were held with the mother before the child was examined, and histories of the types and character of the illnesses were carefully checked. In general, the health histories obtained are believed to present a reasonably accurate account of all serious and prolonged illnesses during infancy and childhood. The types of illness included many of the rare as well as the ordinary childhood diseases. The incidence of illnesses during the first twelve years of life ranged from one to sixteen, exclusive of colds and rickets. The average number of illness episodes reported per child was six, with 13 per cent having had a history of nine or more illnesses and 14 per cent of three or fewer illnesses during infancy and childhood. Growth records were based on repeated measurements for eighteen physical traits on 218 boys and 197 girls from 7 to 12 or 13 years of age, taken without clothing by anthropometrists of the McCormick Fund. Final measurements also on 165 boys and 124 girls to 20 years of age were recorded. Evidence was not obtained of any general relation of illness histories to either rate of growth during middle and late childhood or size at maturity. The correlation gave no suggestion of any permanent deleterious effect of frequent sickness per se.

FOURTH OF JULY INJURIES

Last year the American Medical Association resumed its annual summary of the injuries resulting from the celebration of the Fourth of July. In 1937 twenty deaths resulted from fireworks and firearms; two cases of tetanus occurred and there were 7,205 injuries. With the Fourth again imminent, unnecessary carnage already has begun to appear, one of the Chicago papers for June 16 carrying a report of a 7 year old boy who suffered severe burns of the face from placing a firecracker which he had found in the yard in his mouth to "smoke it." Again the cooperation of hospitals throughout the country has been requested to assist in carrying to the public consciousness the dangerous and unnecessary hazard of allowing fireworks to be sold indiscriminately.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST: SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Society News.—Dr. Samuel L. Ledbetter, Birmingham, discussed "Preoperative and Postoperative Treatment of Goiter" before the Calhoun County Medical Society in Anniston recently.—Dr. Edward C. Rosenow, Rochester, Minn., among others, addressed the annual meeting of the Alabama Dental Association in Birmingham, recently, on "Elective Localization of Streptococci and the Relationship of Dental Sepsis to General Health."—The Jefferson County Medical Society was addressed in Birmingham, recently, by Dr. Albert Graeme Mitchell, Cincinnati, on "Commonplace Endocrine Problems of Childhood." Dr. Hugh H. Young, Baltimore, discussed the removal of adrenal tumors before the society recently and Dr. Edgar W. Davis, Washington, D. C., on the scope of thoracic surgery.—Ernest C. Faust, Ph.D., professor of parasitology and member of the department of tropical medicine, Tulane University of Louisiana School of Medicine, New Orleans, gave the annual guest lecture of the Mobile Academy of Science, May 4, on "Malaria, with Special Reference to Its Epidemiology, Geographic Distribution and Prevalence in the Southern United States."

CALIFORNIA

Hospital News.—A bond issue was recently approved to finance the construction of a wing to the Palo Alto Hospital, on the campus of Stanford University. The new unit will provide eighty additional beds, doubling the present capacity of the hospital.

Personal.—Dr. Joseph M. Brown has been appointed health officer of Ferndale to succeed Dr. Oliver B. Barron and Harry W. Pasley of Reedley, succeeding Dr. Roy E. Allen.—The degree of doctor of laws was conferred on Dr. Jacob C. Geiger, director of public health of San Francisco, by the University of Santa Clara at its commencement June 4.

CONNECTICUT

Dr. Ross Harrison Retires.—Dr. Ross G. Harrison, since 1927 Sterling professor of biology, Yale University School of Medicine, New Haven, retired from active teaching at the end of the academic year. A dinner was held in his honor May 29 at the Osborn Zoological Laboratory, of which he is director. Born in Germantown, Pa., Jan. 13, 1870, Dr. Harrison received a degree of doctor of philosophy at Johns Hopkins University School of Medicine, Baltimore, in 1894, and a medical degree at the University of Bonn in 1899. He lectured in morphology at Bryn Mawr College, 1894-1895; taught anatomy at Johns Hopkins from 1896 to 1907, becoming in this year professor of comparative anatomy, a position he held until 1927 when he was appointed Sterling professor of biology at Yale. He has been managing editor of *The Journal of Experimental*

Zoology since 1906. Societies of which he has been president include the American Society of Zoologists, 1924; American Association of Anatomists, 1912-1913; Anatomische Gesellschaft, 1934-1935, and the American Society of Naturalists. In 1914 he was awarded the Archduke Rainer medal of the Imperial Royal Zoological Botanical Society of Vienna. He has also been given the John Scott Medal and premium by the city of Philadelphia "for the invention of devices for tissue grafting and for tissue culture."

DELAWARE

Society News.—Dr. Francis C. Grant, Philadelphia, addressed the New Castle County Medical Society in Wilmington May 17 on "Diagnosis and Treatment of Spinal Cord Tumors." Dr. George Wilson, Philadelphia, discussed "Insulin in Mental Disease" at a meeting of the society April 19 and Dr. Richard Carmichael Tilghman, Baltimore, addressed the society recently on "Heart Disease in Pregnancy."

GEORGIA

New Superintendent at Hospital.—Dr. Ralph E. Porter, superintendent of the U. S. Marine Hospital, Fort Stanton, N. M., since 1934, has been appointed to a similar position at the marine hospital in Savannah. He succeeds Dr. Joseph S. Bolten who has been assigned to Washington. Dr. Porter has been associated with the U. S. Public Health Service since 1916.

Refresher Courses in Dentistry.—Walter C. McBride, D.D.S., Detroit, Mich., opened a series of refresher courses in children's dentistry under the auspices of the state department of health and the Georgia Dental Association. The following centers were selected for the lectures: Albany, May 23; Waycross, May 24; Swainsboro, May 25; Athens May 26, and Rome, May 27.

ILLINOIS

Spotted Fever.—Two cases of Rocky Mountain spotted fever have been reported in Marshall County thus far this year, one of which was fatal, newspapers reported June 15. The disease was first reported in Illinois in 1934. In 1935 there were five cases and six each in 1936 and 1937.

Chicago

Society News.—The Chicago Society of Allergy was addressed May 16 by Drs. Rudolph H. Hecht and Ben Z. Rappaport on "Infantile Eczema from the Viewpoint of the Allergist" and Tell Nelson, "Antigenicity of Horsehair."—The Chicago Roentgen Society was addressed May 12, among others, by Drs. Isador S. Trostler on "A Slipped Sacro-Iliac Joint" and Louis J. Tint, "X-Ray Findings in Sciatica."—At a meeting of the Chicago Ophthalmological Society, May 9, Drs. Harry W. Woodruff, Joliet, spoke on "Epithelial Corneal Graft for Recurrent Pterygium" and Agnes Beulah Cushman showed pictures of the International Congress of Ophthalmology at Cairo.—Dr. Melvin S. Henderson, Rochester, Minn., addressed the annual meeting of the Chicago Orthopaedic Society June 10 on "Use of Bone Grafts in Ununited Fractures of the Neck of the Femur" and Dr. Samuel Kleinberg, New York, "Slipping of the Femoral Capital Epiphysis."—A symposium on tuberculosis was presented before the German Medical Society of Chicago June 7 by Drs. Henry C. Swcany, Frederick Gruneck, George C. Turner and Richard M. Davison.

INDIANA

Personal.—Dr. Arthur W. Records has been appointed a member of the Franklin board of health to succeed the late Dr. Daniel R. Saunders.—Dr. James M. Hicks Jr., Huntington, has been appointed a member of the state board of medical examiners succeeding the late Dr. Leslie C. Sammons, Shelbyville. He will serve until 1941.—Dr. Henry F. Beckman, professor of obstetrics, Indiana University School of Medicine, Indianapolis, was presented with the annual award of merit of the Northwestern University Alumni Association in Indianapolis.

New Clinical Building at Medical School.—The new six story clinical building of the University of Indiana School of Medicine, Indianapolis, was dedicated May 14. The unit cost more than \$600,000 and was partly financed by the PWA. The speakers at the dedicatory program included Dr. Dean Lewis, professor of surgery, Johns Hopkins University School of Medicine, Baltimore, whose subject was "Teaching the Medical Students How to Reduce the Cost of Medical Care"; Gov. M. Clifford Townsend; Herman B. Wells, A.M., president of

Indiana University; William Lowe Bryan, LL.D., president emeritus, and Dr. Willis D. Gatch, dean of the medical school. Enlarged facilities for the treatment of cancer are a feature of the new building.

IOWA

Personal.—Dr. Russell R. Hansen has been appointed health officer of Storm Lake, succeeding Dr. Edgar F. Smith who recently resigned after holding the position for eight years.—At a dinner held in honor of Dr. John H. Hovenden's completion of forty years of practice in Laurens, he was presented with a watch.—Dr. Charles V. Edwards, Council Bluffs, has been appointed assistant professor of obstetrics at Creighton University School of Medicine, Omaha.

Society News.—Dr. James H. Means, Boston, discussed "Medical Aspects of Preoperative and Postoperative Care" before the Linn County Medical Society, Cedar Rapids, May 26; Dr. Loyal Davis, Chicago, spoke on "Surgical Treatment of Peripheral Nerve Injuries" before the society recently.—Dr. Samuel M. Feinberg, Chicago, discussed "Summer Allergy" before the Clinton County Medical Society at Clinton May 5.—Drs. Harold J. McCoy spoke on "Hereditary Ocular Defects with Blindness" and Harry C. Willett, "Instability of the Neurovascular System as an Etiological Factor in Dermatitis" at a meeting of the Des Moines Academy of Medicine and the Polk County Medical Society recently.

LOUISIANA

Personal.—Dr. Theodore J. Dimitry, professor of ophthalmology, Louisiana State University Medical Center, New Orleans, has been appointed chairman of a monument committee to develop New Orleans as a city of monuments. It is planned to beautify the city's grounds with appropriate monuments, making Tulane Avenue the medical avenue of the city.—Dr. Edwin A. Socola has been promoted to clinical professor of pediatrics at Louisiana State University Medical Center, New Orleans, and Dr. Athol S. Kenney, assistant professor of pediatrics.

MARYLAND

Society News.—The Maryland Academy of Medicine and surgery was addressed in Baltimore recently by Drs. Edward A. Looper on "Diagnosis and Treatment of Infections of the Nasal Accessory Sinuses" and William H. Toulson, "Some Aspects of Genito-Urinary Tuberculosis."

Library Association's Lecture on Dentistry.—Dr. George G. O'Brien, assistant clinical professor of medicine, Loyola University School of Medicine, Chicago, delivered the second annual lecture of the Clarence F. Grieves Library Foundation of the Maryland State Dental Association recently in Baltimore; his subject was "Arthritis and Its Relation to Dentistry."

MASSACHUSETTS

Hospital Observes Twenty-Fifth Anniversary.—At a three day celebration May 5-7 the Peter Bent Brigham Hospital, Boston, observed its twenty-fifth anniversary in conjunction with a reunion of the graduates of the professional and nursing services of the hospital. The speakers included Gov. Charles F. Hurley; Mayor Maurice J. Tobin; Drs. Dean Lewis, Baltimore; Henry A. Christian, Elliott C. Cutler and Charles Sidney Burwell, Boston.

MICHIGAN

Meeting on Industrial Hygiene.—The Michigan Society of Industrial Hygiene held a dinner meeting at the Detroit-Leland Hotel, Detroit, May 25, and presented a symposium on the state, legal, engineering and medical aspects and current problems of industrial hygiene.

Hospital News.—A \$160,000 building is nearing completion at Ypsilanti State Hospital for occupational therapy facilities. About 1,200 patients will benefit because 700 patients of the total at the hospital are now and will continue to be engaged in farming, carpentry, institutional laundering, house-keeping, kitchen work and grounds maintenance, it was stated.

Physician Mayors.—The following physicians have been elected mayors of the places indicated, according to the state medical society:

Dr. Thomas E. DeGurse, Marine City.
Dr. Frank V. Carney, St. Clair.
Dr. Arnold R. Miller, Harrisville.
Dr. Alden G. Sheets, Eaton Rapids.
Dr. Buell H. Van Leuven, Petoskey.

County Society Honors Past Presidents.—The Wayne County Medical Society honored its living past presidents at a meeting May 16 in Detroit. Keys containing miniature gavels wrought in gold were presented to the twenty-five living past presidents and a plaque was unveiled by Dr. Alexander W. Blain in memory of Dr. Arthur D. Holmes. Dr. Clarence E. Umphrey, the immediate past president, was given a silver tea service by the general membership.

Society News.—Dr. Clair Fremont Vale, Detroit, recently discussed "Cancer of the Stomach" before the Jackson County Medical Society, Jackson.—The Genesee County Medical Society was addressed May 4 by Drs. Andrew C. Ivy and Latham A. Crandall Jr., both of Chicago, on "Clinical Aspect of the Physiology of the Gallbladder" and "Problem of Vitamins and Their Clinical Uses."—Dr. Michael L. Mason, Chicago, addressed the Muskegon County Medical Society in Muskegon May 22 on "Management of Open Wounds." Dr. Harold L. Morris, Detroit, addressed the society June 17 on "Pyelitis of Pregnancy."

MINNESOTA

State Medical Meeting at Duluth.—The eighty-fifth annual session of the Minnesota State Medical Association will be held at the Hotel Duluth, June 29-July 1. Dr. James M. Hayes, Minneapolis, will deliver the presidential address on "Medical Problems in Minnesota." Out-of-state speakers will include:

Dr. Irvin Abell, Louisville, Ky., Carcinoma of the Colon and Rectum.
Dr. Roland S. Cron, Milwaukee, Wis., Uterine Malignancy.
Dr. Howard W. Haggard, New Haven, Conn., Recent Advances in Medicine and Their Social Significance.
Dr. Philip Lewin, Chicago, The Foot and Ankle—Their Discomforts—Deformities and Disabilities.
Dr. Karl A. Meyer, Chicago, Recent Advances in the Treatment of Burns.
Dr. Eli K. Marshall Jr., Baltimore, Sulfanilamide in Bacterial Infections.
Dr. Charles Anderson Aldrich, Winnetka, Ill., Some Practical Points in the Management of Nephritic Children.
Dr. Edward Jackson, Denver, Recognition and Treatment of Refractive Errors in Children.

The first Herman M. Johnson Memorial Lectureship will be delivered Friday by Gov. Elmer A. Benson. Dr. Haggard will address the annual banquet Thursday evening; he will also address the public health meeting at the Orpheum Theater together with Dr. Abell. Dr. Hollis E. Potter, Chicago, will deliver the Russell D. Carman Memorial Lecture Wednesday afternoon on "The Diagnostic Roentgenology of Adult Pulmonary Tuberculosis with a New Suggestion as to Group Survey." The Southern Minnesota Medical Association will present its annual gold medal for the best scientific exhibit Thursday evening. The Minnesota Academy of Ophthalmology and Otolaryngology will hold a special dinner meeting at the Kitchi Gammi Club Friday in honor of Dr. Jackson who plans to give a course of lectures at St. Mary's Hospital, June 30-July 2, under the academy's auspices, on "Practical Aspects of Physiological Optics in Refraction." The annual golf tournament will be held Saturday morning at the Northland Country Club.

MISSISSIPPI

Health Officer Goes to Oklahoma.—Dr. John W. Shackelford, for eight years director of the Washington County health department, has resigned to become director of the technical field unit and serve as advisory officer for health units with the Oklahoma State Department of Health. He will begin his new work August 15, it was reported. Dr. Shackelford graduated at Tulane University of Louisiana School of Medicine, New Orleans, in 1926. He will be succeeded as county health officer by Dr. George W. Mast, Lexington, who now holds a similar position in Holmes County.

MISSOURI

Society News.—Dr. William W. Buckingham, Kansas City, discussed "Indications for Collapse Measures in Pulmonary Tuberculosis" before the Jackson County Medical Society May 24.—Dr. Hiram Winnett Orr, Lincoln, Neb., addressed the Buchanan County Medical Society in St. Joseph recently on "Prevention and Control of Infection in Injuries to Bones and Joints."—Dr. William A. Hudson, Detroit, addressed a joint meeting of the Trudeau Club of St. Louis and the St. Louis Medical Society recently on "Collapse Therapy—Its Principles and Application in the Treatment of Pulmonary Tuberculosis."—At a meeting of the Kansas City Society of Ophthalmology and Otolaryngology recently the speakers included Drs. De Forrest C. Jarvis, Barre, Vt., on "Value of 3-Unit Doses of Insulin in Ophthalmology and Otolaryngology" and "Applied Body Chemistry in Ophthalmology and

Otolaryngology," and James W. White, New York, "Method of Checking Muscle Imbalance" and "Convergence Insufficiency with a Vertical Imbalance."

MONTANA

Personal.—Dr. Byron L. Pampel, Livingston, has been named superintendent of the state hospital at Warm Springs. —Dr. Enoch M. Porter, Great Falls, was elected president of the state board of health at its recent meeting in Helena.

NEVADA

Plague Infection.—Plague infection has been found in fleas collected from Mohave Desert wood rats in Clark County: from rats trapped April 14, 14½ miles northwest of Las Vegas; from rats trapped April 18, 14 miles northwest of Las Vegas; from rats trapped April 19, 17 miles northwest of Las Vegas; from rats trapped April 20, 21 miles northwest of Las Vegas; from rats trapped April 21, 23 miles northwest of Las Vegas; from rats trapped April 22, 17 miles northwest of Las Vegas.

NEW JERSEY

Public Health Week.—The Bergen County Medical Society sponsored a public health week program May 7-14. The publication of a special medical section in the *Bergen Evening Record* opened the week's program. Other features included health movies, exhibits and lectures, and an x-ray clinic for Negroes. The section in the *Evening Record* contained sixteen pages of articles written by physicians and dentists, reproductions of pictures of members of the county medical society and advertisements.

Society News.—The Bergen County Council of Social Agencies sponsored a one day institute on welfare problems in Hackensack May 23. —At a meeting of the Essex County Medical Society in Newark recently, Dr. Thomas A. Shallow, Philadelphia, discussed "Carcinoma of the Thyroid Gland." —Dr. John H. Gunter, Philadelphia, addressed the Gloucester County Medical Society on "Dental Problems of Interest to Physicians." —At a meeting of the Passaic County Medical Society in Passaic recently, Dr. S. Bernard Wortis, New York, read a paper by Dr. Foster Kennedy, New York, on "Allergy in Nervous and Mental Disease." —At the second annual meeting of the New Jersey Association of School Physicians in Atlantic City May 20 one session was devoted to a discussion of childhood tuberculosis with the following speakers: Drs. Berthold S. Pollak, Secaucus; Max Horn, Newark, and Irving L. Applebaum, Newark. Other speakers were Drs. Aaron H. Horland, Newark, on "The School Physician as the Representative of Organized Medicine in the Public Schools" and Harry B. Silver, Newark, "Our Relation to the State Medical Society."

NEW YORK

Consultants to Police Department.—A police scientific staff, composed of sixteen members, has been formed in Buffalo to serve as consultants to the local police. It is under the supervision of the police commissioner and five rooms are provided in police headquarters to house the ballistic, chemical and photographic laboratories and the rooms necessary for the polygraph. Meetings are held at regular intervals and all members are subject to call as the necessity arises. The following are members:

Dr. Charles W. Bethune, moulage expert.
C. Merrill Brown, M.A., microchemist.
Dr. John Burke, medical photographer.
Dr. William F. Burke, polygraph expert.
G. H. Cartledge, Ph.D., inorganic chemist and spectroscopic analysis.
Dr. Rocco N. De Dominicis, pathologist.
Dr. Karl F. Eschelman, firearms identification and ballistics.
Aaron A. Goldstein, librarian and secretary.
Dr. Charles E. Long, medical examiner.
William F. Payne, microscopic photography and x-ray.
Edward J. Powers, city chemist.
M. C. Rinhardt, M.A., physicist.
Clifford E. Rose, D.D.S., cryptography and dental identification.
Dr. Harry M. Steen, pathology and biochemistry.
A. P. Sy, Ph.D., toxicologist.
Dr. Victor A. Tyrasinski, police surgeon.

New York City

Dr. Cannon Delivers Welch Lectures.—Dr. Walter B. Cannon, George Higginson professor of physiology, Harvard University Medical School, Boston, delivered the William H. Welch Lectures at Mount Sinai Hospital in May; his subjects were "Some New Aspects of Homeostasis" and "The Aging of Homeostatic Mechanisms."

Appointments to New York Polyclinic.—The following have been appointed to the New York Polyclinic Medical School and Hospital:

Dr. Joseph F. McCarthy, professor of urology and attending urologist.
Dr. Charles J. Imperatori, professor of otolaryngology and attending otolaryngologist.

Dr. Joseph E. J. King, professor of neurosurgery and attending neurosurgeon.

Dr. Edward H. Dennen, professor of obstetrics and attending obstetrician.

Mosquito Eradication.—Under a recently approved WPA schedule, \$2,540,000 will be expended for further control and eradication of mosquitoes and insect pests in the low lying sections of New York, especially Queens, it is reported. The major phase of the work will require the digging of ditches and the construction of retaining walls and dikes in swamps and ponds. According to the present plans 35 per cent of the operations will be done in the Queens sections, 20 per cent each for Brooklyn and Bronx low lying areas, 18 per cent in Staten Island and 7 per cent in Manhattan. In Queens the areas to be treated will include those surrounding the World's Fair grounds and others sections of Flushing, Howard Beach, Casino Park, South Aqueduct and south of Jamaica. In Brooklyn work will be done in the Casino and Bergen Beach sections; in the Bronx, the Pelham Bay marshy areas. In Staten Island, in Rosebank, Eltingville, Richmond Village, New Springville and Annadale.

Dr. Alger Wins Leslie Dana Medal.—Dr. Ellice M. Alger, professor of clinical ophthalmology, New York Post-Graduate Medical School and Hospital, has been awarded the Leslie Dana Gold Medal, given each year for "outstanding achievements in the prevention of blindness and the conservation of vision." Dr. Alger was selected for this honor by the Association for Research in Ophthalmology in cooperation with the St. Louis Society for the Blind, through which the medal is offered by Mr. Leslie Dana, St. Louis. Dr. Alger was one of the founders in 1915 of the National Society for the Prevention of Blindness and he has served continuously on its board of directors. The inscription on the 1938 medal refers to Dr. Alger as "A Pioneer in Sight Conservation—Wise, Understanding and Sympathetic Counsellor." Dr. Alger is 67 years of age and graduated at the University of Vermont College of Medicine, Burlington, in 1893. He formerly served as chairman of the Section on Ophthalmology of the New York Academy of Medicine.

Society News.—The New York State Society of Pathologists adopted its constitution and elected the following officers, among others, at a meeting May 10; Drs. William S. Thomas, president; Armin V. St. George, vice president, and Maxwell J. Fern, secretary treasurer. Committees were appointed to undertake to improve the economic situation of pathologists in the state. —The Bronx County Medical Society was addressed May 18 by Drs. Joseph Lawrence on "Legislation Affecting the Medical Profession"; George I. Swetlow, "Highlights in the Historical Development of Medical Jurisprudence," and Maxwell M. Booxbaum, Mount Vernon, N. Y., "The Doctor in the Witness Chair." —Dr. Harry J. Epstein, among others, addressed the Bronx Gynecological or Obstetrical Society May 23 on "Management of Delivery in Multiple Pregnancies." —At a meeting of the Medical Society of the County of New York May 23, the speakers were Drs. James Alexander Miller on "Some Unsolved Problems in Tuberculosis" and Howard W. Haggard, New Haven, Conn., "Medical Science and Medical Progress."

Joint Group Cooperates in School Health.—A committee has been established, representing the department of health and the board of education, to coordinate problems relating to the welfare of pupils, according to the *New York Times*. The new setup will prevent duplication, loss of time and frequent overlapping of effort, it was stated. The department of health has jurisdiction over the physicians and nurses, while the board of education's bureau of health education supervises the general health program. This is the first permanent committee to be set up to coordinate action on health problems by the two departments. At a meeting to be held early this month, the scope of the committee's duties will be outlined. Under existing regulations, courses in health education are given and better health habits among the pupils are developed. It will be possible now to conduct such major projects as chest x-ray examinations for tuberculosis and other health undertakings with the cooperation of the health department. The schools will continue teaching the health habits and the health department will provide medical examinations to pupils and give "advice and counsel" to school officers.

NORTH CAROLINA

Hospital News.—The Granville Hospital with a capacity of forty-five beds was opened recently at Oxford; it replaces the old Brantwood Hospital.—A medical library is being established at Grace Hospital, Banners Elk, in memory of the late Dr. Ronda H. Hardin, a member of the staff for many years.

University News.—Recent speakers at Duke University include Dr. Harold W. Brown, Chapel Hill, on hookworm and Vilhjalmur Stefansson, arctic explorer, on diet in primitive people. Dr. Hugh H. Trout, Roanoke, Va., conducted a clinic and showed a motion picture on radical mastoidectomy.

Seminar on Tuberculosis.—The second annual seminar on tuberculosis will be held at Asheville July 11-16. Special attention will be paid to early diagnosis and to both surgical and medical treatment. Registration will be limited to twenty and applications will be acted on in the order in which they are received; the fee is \$10. Dr. Karl Schaffle, Arcade Building, Asheville, is chairman of the seminar.

Members of State Medical Board.—At the annual meeting of the North Carolina State Medical Society in Pinchurst May 4, the following members of the North Carolina Board of Medical Examiners were elected: Drs. Lewis W. Elias, Asheville; William D. James, Hamlet; Karl Busbee Pace, Greenville; Frank Alexander Sharpe, Greensboro; William M. Coppridge, Durham; James S. Brewer, Roseboro, and Lester Avant Crowell Jr., Lincolnton.

OHIO

Physicians' Orchestra.—The Doctors Symphony Orchestra gave its seventy-first concert at the City Hospital of Akron May 5. Dr. Alexander S. McCormick was director and D. H. Henninger, D.D.S., concertmaster.

Society News.—Dr. Thomas E. Jones, Cleveland, addressed the Clark County Medical Society, Springfield, recently on "Diagnosis and Treatment of the Commoner Diseases of the Colon and Rectum."—Dr. Clifford G. Foor, Hillsboro, addressed the Clinton County Medical Society recently on "Diseases of the Thyroid Gland and Their Treatment."—Dr. John E. Hoberg, Columbus, addressed the Hempstead Academy of Medicine, Portsmouth, recently on "Pyelitis in Children and in Pregnancy."—Dr. Harry L. Rockwood, superintendent of Mount Sinai Hospital, Cleveland, was elected president of the Ohio Hospital Association at its annual meeting in Columbus recently. Dr. Fred G. Carter, superintendent of Christ Hospital, Cincinnati, was installed as president.

History of Medicine in Ohio.—The Ohio Committee on Medical History and Archives of the Ohio State Archaeological and Historical Society held its first meeting at the Neil House, Columbus, May 12. The committee was organized to compile a medical history of the state. Books, reprints, transactions, instruments, prescriptions, account books, saddle bags, instrument cases, diplomas, letters, diaries, genealogies and photographs and anything pertaining to the early practice of medicine in Ohio from 1788 to 1890 are especially desired. The Ohio State Archaeological and Historical Museum will become the custodians of all the material acquired. The project is the outgrowth of a suggestion to Dr. Jonathan Forman, Columbus, editor of the state medical journal, by Robert G. Paterson, Ph.D., executive secretary of the Ohio Public Health Association, proposing the establishment of a committee on medical history. Provision was made for extension of the committee and invitations were sent to interested persons throughout the state.

OKLAHOMA

Memorial to Dr. Garabedian.—The library of the late Dr. Garabed A. Z. Garabedian was recently presented to the Tulsa County Medical Society by Mrs. Garabedian. The collection on pediatrics will serve as a memorial to Dr. Garabedian.

Society News.—The Kay County Medical Society was addressed at Blackwell recently by Drs. Arthur E. Bence and Howard C. Clark, Wichita, on "Fractures of the Spine" and "Endometriosis" respectively.—Dr. Fred E. Angle, Kansas City, Kan., discussed undulant fever before the Garfield County Medical Society in Enid May 26.

University News.—A new building for biological sciences was recently dedicated at the University of Oklahoma. The unit was financed by a PWA grant of \$204,000 while \$47,000 was given by the state legislature for equipment. Lorande Loss Woodruff, Ph.D., protozoologist, Yale University, was

the guest speaker; his subjects were "Paramecium, Past and Present" and "Philosophers in Little Things." The dedicatory address was given by President William Bennett Bizzell, LL.D., who spoke on "The University, Biology and the State."

PENNSYLVANIA

Society News.—The Cambria County Medical Society was addressed in Johnstown June 9, among others, by Dr. William J. Mallory, Washington, D. C., on "Diagnosis and Management of the Common Diseases and Disturbances of the Digestive Tract."—Dr. George R. Harris, Pittsburgh, addressed the Armstrong County Medical Society in Kittanning June 8 on "Our Responsibilities as Molders of Public Opinion."—At a meeting of the Washington County Medical Society in Washington May 11, Drs. Guy M. Nelson and Adolph A. Walking, Philadelphia, discussed management of gallbladder disease.

Philadelphia

Dr. Mohler Named Dean of Jefferson.—Dr. Henry K. Mohler, medical director of the Jefferson Medical College Hospital, Philadelphia, has been appointed dean of Jefferson Medical School, succeeding the late Dr. Ross V. Patterson, effective August 1. Dr. Mohler graduated at the Philadelphia College of Pharmacy. He received his degree in medicine at Jefferson in 1912, becoming medical director of the hospital in 1914. During 1913-1914 he was in charge of the laboratory of clinical medicine at the college, serving as instructor in medicine from 1913 to 1922, when he became demonstrator. He was associate in medicine from 1925 to 1929. Subsequently he served as assistant professor in medicine, associate professor in medicine and clinical professor of therapeutics.

Society News.—Among others, Drs. Maurice Muschat addressed the Philadelphia Urological Society May 23 on "Hormonal Activity in Prostatic Hypertrophy" and James F. McCahey, "The Embryological and Histological Basis for Virilism and Hermaphroditism."—The speakers before the Philadelphia Neurological Society May 27 included Dr. Gabriel A. Schwarz on "Compression of the Spinal Cord in Osteitis Deformans of the Vertebrae."—A symposium on syphilis was presented at a meeting of the Philadelphia County Medical Society May 11 with Surg. Gen. Thomas Parran of the U. S. Public Health Service as the guest speaker. Philadelphia speakers were Drs. Frederick S. Baldi, Philip Q. Roche, Baldwin L. Keyes and Daniel J. McCarthy.—Dr. Lester W. Sontag, Yellow Springs, Ohio, addressed the Philadelphia Roentgen Ray Society May 5 on "Evidences of Disturbed Prenatal and Neonatal Growth in Bones of Infants at One Month"; Drs. Jeremiah Fletcher Lutz and Lewis C. Pusch, York, Pa., spoke on "Angio-Endothelioma of Bone."—Dr. Henry P. Brown Jr. delivered the annual oration of the Philadelphia Academy of Surgery May 16 on "Acute Osteomyelitis."

Pittsburgh

Pitt Medical Alumni Homecoming.—Alumni of the University of Pittsburgh School of Medicine held its annual homecoming June 2. The program included a symposium on recent developments in therapeutics with Drs. Murray B. Ferderber, John V. Shirer, William W. G. MacLachlan and Samuel R. Haythorn and Donald A. Wilson, Ph.D., as the speakers. A smoker was also given.

The Smoke Nuisance.—A study of the smoke problem in Pittsburgh was begun early in May under the auspices of the WPA and medical and scientific societies. The program includes the measurement of smoke coming from the chimneys and smokestacks and the tabulation of information given in questionnaires. Employers and employees in the milk business have joined to effect the delivery of the health questionnaires and the newspapers and health authorities cooperated in appealing to heads of households to answer the blanks, leaving them in their empty milk bottles to be picked up by the milk drivers. In ascertaining the number of colds, sore throats and other disorders of the nose, throat and lungs reported by families, it is hoped to determine whether, in a measure, these ailments might be caused by breathing smoke into the lungs. Agencies cooperating in the study include the Allegheny County Medical Society, General Health Council, the Air Hygiene Foundation of the Mellon Institute, department of industrial hygiene, University of Pittsburgh, Singer Memorial Research Laboratory and the U. S. Bureau of Mines. Similar surveys have been conducted in St. Louis, Indianapolis and New York; it is reported.

SOUTH CAROLINA

Superintendent of Training School Honored.—A portrait of Dr. Benjamin O. Whitten, superintendent, state training school at Clinton, was unveiled April 25. The portrait is the gift of more than 100 employees at the institution. Dr. Whitten has been superintendent since the school was opened in 1920. Dr. Frederick L. Webb, medical director, presided, and F. D. Jones, D.D., director of religious activities at the school, spoke in behalf of the employees. Dr. Whitten is 51 years of age and a graduate of Atlanta College of Physicians and Surgeons, class of 1913.

District Meetings.—At a meeting of the First District Medical Society in Walterboro recently the speakers included Drs. Robert B. Taft, Charleston, "Purpura Haemorrhagica with Reference to Radium Treatment"; John W. Regan, "Use of Sulfanilamide"; Robert Wilson Jr., "Protamine Insulin"; George R. Dawson, "Blood Transfusion Technic (Review of 1,000 Cases)," and John M. van de Erve, "Color Photography for Medical and Surgical Case Records"; all are of Charleston. —The Fifth District Medical Society was addressed in Lancaster, among others, May 11, by Drs. Carl A. West, Camden, on appendicitis; John M. Settle, Great Falls, tularemia; William B. Ward, Rock Hill, cyclopropane.

VIRGINIA

Health Department Activities.—A new full time health department will begin functioning in Buchanan County July 1. Since April 1, 1936, the county's health activities were conducted as a part of a district composed of Tazewell, Russell and Buchanan counties. Headquarters for the new unit will be in Grundy.

Personal.—Dr. William Y. Garrett, Raven, has been appointed health officer of Prince William County.—Dr. Ralph G. Beachley, deputy director of rural health in the state department of health, has been appointed health officer of Arlington County, to succeed Dr. Earle G. Brown, who recently became health officer of Nassau County, New York.

Portrait of Dr. J. S. D. Cullen.—A portrait of the late Dr. J. S. Dorsey Cullen, formerly member of the Medical College of Virginia and dean from 1886 to 1898, has been presented to the school by his grandson, Lieut. Dorsey H. Cullen of the U. S. Army. The work of Gaetan de Navailles, Paris, the portrait shows Dr. Cullen as a medical officer of the Confederate Army and will be placed on the walls of the library. Dr. Cullen was the son of Dr. John Cullen, one of the founders of the medical college. He was the first professor of diseases of women and children at the school, serving in this position from 1868 to 1881, when he succeeded Dr. Hunter McGuire as professor of surgery. He was a charter member of the Medical Society of Virginia and was at one time president of the Richmond Academy of Medicine.

WASHINGTON

Society News.—The King County Medical Society was addressed June 6 by Drs. James M. Bowers and Samuel T. Mercer on "Gout" and "Cutaneous Manifestations in the Leukemias" respectively. Dr. William Dressler, Vienna, discussed "Errors in the Diagnosis and Treatment of Heart Disease" at a meeting May 31. The society and its woman's auxiliary cooperated in conducting a hobby show May 23; a showing for the public was held May 24.

WISCONSIN

County Societies Sponsor Orthopedic Clinics.—Various county medical societies in the state have cooperated with the crippled children's division of the state department of public instruction in holding orthopedic clinics. Included among them are:

Outagamie County Medical Society in Appleton April 2.
Kenosha County Medical Society in Kenosha April 27.
Douglas County Medical Society in Superior May 14.
Portage County Medical Society in Stevens Point May 21.

District Meetings.—The Sixth Councilor District Medical Society was addressed at its annual meeting in Green Bay May 24 among others by Drs. Donne F. Gosin on "Segmental Enteritis"; William E. Grove, Milwaukee, "Deep Infections of the Neck" and Robert L. Cowles, "Congenital Pyloric Stenosis."—At the ninth annual meeting of the Ninth Councilor District Medical Society in Stevens Point May 5, Dr. M. Herbert Barker, Chicago, conducted a clinic on cardiovascular diseases and hypertension; he also presented a review of recent methods in the treatment of hypertension at the

dinner in the evening; Dr. James M. Hayes, Minneapolis, discussed "Acute Surgical Conditions of the Abdomen" and Dr. Albert E. Rector, Appleton, president elect, state medical society, spoke.

GENERAL

Medical Journals Merge.—The *Review of Tumor Therapy* and the *Southern Surgeon* have been merged. In announcing this, THE JOURNAL, June 4, reported that financial difficulties were responsible for the change. The editors of the *Southern Surgeon* wish to correct any misapprehension concerning this journal's financial status, stating that it has "always been in the black and was never more securely so than at this time." The *Review of Tumor Therapy* was taken over by the *Southern Surgeon* and is now run as a section in the latter publication under the title of Review of Neoplasms.

Medical Section of Association for Advancement of Science.—The one hundred and second annual meeting of the American Association for the Advancement of Science will be held at Ottawa June 27-July 2. The section on medical sciences (N) will meet Tuesday and Wednesday. There will be a symposium on "Bacillus Calmette-Guérin." Wednesday the session will be a joint symposium with the Section on Chemistry (C). The subjects will include: Hormones and Immunity; Bioelectric and Other Physiological Responses of Insulin and Nutrazol; The Prolongation of the Action of Insulin; The Purification of Heparin; The Ketogenic and Anti-Insulin Properties of Anterior Lobe Extracts, and Studies on the Specific Metabolic Stimulant of Pituitary Extracts.

Winners in Syphilis and Tuberculosis Control Contest.—Tacoma, Wash., won the first award in the initial syphilis control contest sponsored this year as a part of the city health conservation contest by the United States Chamber of Commerce and the American Public Health Association. Awards of merit went to Hartford, Conn., Newark, N. J., Louisville, Ky., and New Haven, Conn. In the tuberculosis control contest, the winner is Detroit, with awards of merit going to Newton, Mass., Hartford and New Haven, Conn. Points considered by the committee were the comprehensiveness of case finding and follow-up services in connection with tuberculosis and syphilis, the facilities provided for diagnostic and treatment purposes, and the extent of group participation in programs of education and control.

Bequests and Donations.—The following bequests and donations of medical interest have recently been announced:

New York Society for the Ruptured and Crippled, \$50,000; New York Medical College and Flower Hospital, \$25,000; New York Foundling and Babies hospitals, \$10,000 each, by the will of Mrs. Sophie March Gondran. All are in New York.

Fifth Avenue Hospital, New York, \$100,000 by the will of the late Adolph L. Gondran.

Mount Sinai Hospital, New York, \$35,000 by the will of William Cohen, supreme court justice.

Misericordia Hospital, New York, \$25,000, and St. Vincent's Hospital, \$5,000 by the will of Mrs. Harriet Brady Mathieu.

Montefiore Hospital, New York, \$10,000 by the will of the late Herman Lissner.

New York Ophthalmic Hospital, New York, \$2,000 by the will of the late Eliza Shardlow.

Toledo Hospital, Toledo, Ohio, will receive the bulk of an estate estimated at \$2,000,000 by the will of Frank Collins.

Presbyterian, St. Luke's, Mount Sinai and Post-Graduate hospitals, New York, \$50,000 each, and New York Skin and Cancer Hospital \$25,000 by the will of the late Henry Ware Putnam.

Jewish and Lankenau hospitals, Philadelphia, \$7,000 each by the will of the late Dr. Ellwood R. Kirby.

Methodist Episcopal Hospital, Philadelphia, \$5,000 to establish the William S. Vare endowment, and \$5,000 to the Hospital of the Protestant Episcopal Church for an endowment in memory of her daughter, Ida May Vare, under the will of the late Mrs. Ida Vare, Philadelphia.

Fiftieth Anniversary of Physiological Society.—The American Physiological Society observed its fiftieth anniversary at a banquet at the Lord Baltimore Hotel, Baltimore, April 1. The celebration took the form of a special program during the annual session of the Federation of American Societies for Experimental Biology and the preparation of a history of the society, the first twenty-five years being prepared by Dr. William H. Howell, director emeritus and emeritus professor of physiology, Johns Hopkins University School of Hygiene and Public Health, Baltimore, and the second by Charles W. Greene, Ph.D., Columbia, Mo., for many years secretary and more recently president of the society. Guests of honor at the banquet included four of the five living original members: Dr. Howell, Russell H. Chittenden, Sc.D., emeritus professor of biologic chemistry, Yale University School of Medicine, New Haven; Joseph Jastrow, LL.D., formerly professor of psychology, University of Wisconsin, and Dr. Warren P. Lombard, emeritus professor of physiology, University of Michigan Medical School, Ann Arbor. Dr. Frederick W. Ellis, Newton, Mass., the fifth surviving original member, could not attend. Dr. William T. Porter, Dover, Mass., was made honorary

president for the occasion and presided as toastmaster. The late Dr. John J. Abel, emeritus professor of pharmacology, Johns Hopkins University School of Medicine, was a guest and the British and Canadian physiologic societies were represented by Drs. William H. Newton, of Bucks, England, and Charles H. Best, Toronto.

FOREIGN

Croonian Lectures.—Dr. Francis R. Fraser, professor of medicine, University of London, and director, department of medicine, British Post Graduate Medical School, delivered the Croonian Lectures of the Royal College of Physicians of London May 24, 26 and 31. His subject was "Clinical Aspects of the Transmission of the Effects of Nervous Impulses by Acetylcholine."

Prize for Work on X-Rays.—A David Anderson-Berry Gold Medal and a sum of about £100 will be awarded in July by the Royal Society of Edinburgh to the person who in the opinion of the council has recently produced the best work on the nature of x-rays in their therapeutic effect on human diseases. Applications for the award are invited; they may be based on both published and unpublished work and should be accompanied by copies of the relevant papers. Additional information may be obtained from the General Secretary, Royal Society of Edinburgh, 22 George Street, Edinburgh 2, by June 1.

Society News.—The eighth session of conferences of the International Committee on Military Medicine will be held in Luxembourg July 1-4. Colonel Voncken, Office International de Documentation de Medecine Militaire, Liège, Belgium, is in charge of arrangements.—The second congress on renal insufficiency will be held at Evian, France, September 21-24. Information may be obtained from the secretariat, 138 Avenue des Champs-Élysées, Paris 8.—The tenth International Medical Congress for Psychotherapy will be held at Balliol College, Oxford, July 29-August 2. Additional information may be obtained from the honorary secretary, Dr. Eric B. Strauss, 81 Harley Street, London, W. 1.

Government Services

Cancer Center at Baltimore Marine Hospital

A new 100 bed center for the treatment of cancer patients will begin functioning in September at the U. S. Marine Hospital, Baltimore, under the auspices of the National Cancer Institute. Cancer patients of the twenty-two marine hospitals throughout the country will be eligible for the service, which will be financed by the cancer institute as one of its regular authorized activities. The new model center will give the U. S. Public Health Service facilities for cancer therapy which are too costly to maintain in individual hospitals for the relatively few cancer patients reporting to a single institution for hospitalization, and it will enable the National Cancer Institute to carry out one of the primary functions outlined in the National Cancer Act of 1937—study leading to improvement in the diagnosis and treatment of cancer. The Baltimore hospital has a capacity of 450 beds with adjacent quarters for officers and nurses, a research laboratory in addition to the laboratory for routine clinical examinations, facilities for x-ray diagnosis, physical therapy, dental and eye, ear, nose and throat clinics. Proximity to the future home of the National Cancer Institute in Bethesda, Md., was another factor in the selection of the Baltimore hospital. It is about 30 miles from the Bethesda site, where buildings of the National Institute of Health are already under construction. About 100 bed patients will be accepted at the clinic. The second floor of the hospital will be devoted to the care of bedpatients and to the admission of outpatients. Rooms in the basement will be equipped for x-ray and radium therapy and the pathologic work will be done in the research laboratory. Marine hospital patients amenable to ambulatory treatment may also be sent to Baltimore, but they will have to reside in the city at their own expense.

The cancer treatment center will be furnished with 500 milligrams of radium element and a 200 kilowatt x-ray machine, later to be supplemented with a 1,000,000 or more high voltage machine. The rooms of the hospital which will be assigned for the handling of x-rays and radium will be altered and equipped for adequate protection by the use of lead-impregnated walls and glass. It is estimated that the purchase of the radium and x-ray equipment, together with the necessary structural alterations, will cost approximately \$30,000.

Nonmalignant Stenosis of the Esophagus

In his presidential address to the Section of Surgery of the Royal Society of Medicine, Prof. Grey Turner said that he had been taught that cancer of the esophagus was almost the only cause of obstruction, but he remembered a casual remark made by W. J. Mayo in 1906 that it was always worth doing a gastrostomy because the diagnosis might be wrong. During the last few years Turner had seen many examples of simple stenosis.

CAUSATION

The causation of fibrous stricture was usually obvious, generally the swallowing of corrosive fluid, but there were other causes, such as local or general infections. Milder destructive changes in the esophagus might be induced by regurgitation of very acid or toxic gastric contents and might occasionally lead to stenosis. Brown Kelly, of Glasgow, had shown that a secondary fibrosing condition might begin in association with some congenital defect.

PREVENTION

In the presence of conditions which invariably led to stenosis prevention was important. Salzer advised the passage of instruments in the early days, but this was dangerous; it was better to defer this treatment until four or six weeks after the accident. Turner had seen perforation of the esophagus by a bougie on the twenty-sixth day after the carbolic acid was swallowed. As to the ultimate condition, many patients could be permanently cured by persistent dilation, but in a few the tendency to recur persisted for many years and perhaps throughout life. Other methods were available. The swallowed string, usually associated with the name of Plummer, had a great field of usefulness. Turner had no success with the retrograde passage of a bougie through an artificial gastric fistula, but others had. He condemned attempts at excision of a simple stricture with end to end anastomosis. In cases which defeated the various methods mentioned there was always the possibility of making a new esophagus, but every attempt should be made to restore nature's path before trying to replace it by a surgical exploit.

Osteopath to Be Tried for Manslaughter

Though not recognized by the state, osteopathy is not only tolerated in this country but, like other forms of irregular practice, is patronized by persons of high social position and is often a lucrative business. However, meddling with a dangerous disease may prove serious, as the following case shows. A young school teacher had been under medical treatment for diabetes for some years. According to her physician her condition was satisfactory and likely to remain so provided she followed the dietetic instructions and continued with injections of insulin. She met an osteopath who told her that she had not diabetes and was suffering from anemia. His examination merely consisted of looking at her eyes and feeling her pulse. He told her to fast for four days and take orange juice every two hours. She did so and discontinued her injections of insulin. She became ill, and then the osteopath advised that she be given a little insulin in milk, but she lapsed into coma and died. The osteopath was committed for trial on the charge of manslaughter.

A Standard for Prematurity

In the compilation of the report of Queen Charlotte's Maternity Hospital, the definition of prematurity came in question. It was decided to refer it to the British Paediatric Association and the Section of Diseases of Childhood of the Royal Society of Medicine. These bodies in turn referred it to a committee

of pediatricians, who suggested a standard of 5½ pounds (2,500 Gm.) weight or under. This was circulated to various bodies, including the Royal College of Physicians and the British College of Obstetricians and Gynecologists. Neither of these was satisfied, and a further committee was set up, which included the president of the latter college, Sir Ewen Maclean, and other authorities. This committee came to the conclusion that it was impossible to define prematurity satisfactorily but that some standard was desirable for the purposes for which the proposed definition was intended. They adopted the following resolution: "That in conformity with the standard in international use an infant whose birth weight is 5½ pounds (2,500 Gm.) or less shall be considered, for the purpose of comparison of records, as either immature or prematurely born, according as the estimated period of gestation is full time or less."

Professor Boycott Is Dead

Prof. A. E. Boycott, who was a well known pathologist, has died in his sixty-second year. He was editor of the *Journal of Pathology and Bacteriology*. He became lecturer on pathology at Guy's Hospital in 1907; he was transferred to the chair of pathology at Manchester in 1912 and to that of University College, London, in 1915. At a comparatively early age he established a reputation for his studies in experimental pathology in collaboration with the late Prof. J. S. Haldane. They investigated the anemia of Cornish miners, which was supposed to be due to defective ventilation but was proved by them to be due to ankylostomiasis. Boycott's work on the blood changes in that disease and the problems connected with the passage of the larvae through the intact skin was of the first importance. In collaboration with Haldane he investigated compressed air illness (caisson disease) and showed how divers could safely be decompressed. His early work on the blood changes in ankylostomiasis led to an interest in experimental anemia and blood regeneration, on which he became a leading authority. He also was a naturalist, and snails, which he bred, were a special hobby.

Surplus of the Social Insurance Funds

An editorial in the May 14 issue of the *Journal des Practiciens* on the fate of the surplus funds collected by the social insurance authorities is of interest. The receipts from joint payments by the insured and the employers since 1930, when the law was instituted, to the end of 1936 have been about twenty-one billion francs (nearly \$600,000,000). The disbursements in the form of sickness, maternity and death claims have been only about seven billion francs. All the insurance premiums paid by workers and employers do not remain in the funds of the caisses or bureaus of the social insurance organization. A certain proportion are set aside as a reserve fund; hence the caisses have received only a little over ten billion francs, so that the surplus above payment of claims amounts to three and a half billion francs up to the end of 1936. The question arises, what has become of this surplus? Large sums have been lost, according to the editorial, in lending money to politicians to be used in erection of low-priced dwellings. There has been such a lack of judgment on the part of the social insurance authorities in their investments in the form of buildings, etc., that the French treasury heads have been obliged to intervene.

Pneumococcic Encephalitis

At the May 3 meeting of the Académie de Médecine of Paris, three cases of encephalitis due to the pneumococcus were reported by Professor Marinesco and his co-workers. Three cases of pneumonia complicated by cerebral localization of the pneumococcus were observed clinically, and the condition was

confirmed by studies of the brain tissue obtained at necropsy. Pneumococcic encephalitis differs from other forms of this disease. The lesions involve chiefly the white substance of the cerebrum, giving rise to areas of demyelination with characteristics peculiar to this type of infection. In addition to the myelin tissue, the neuroglia shows evidence of intense changes of toxic origin, reacting by marked mitoses. Perivascular round celled infiltration is a third typical observation, accompanied by punctate hemorrhages in the adjacent brain tissue and blood vessels filled with fibrin. The presence of the pneumococcus in the cerebral tissue was confirmed by staining and culture.

Excessive Speed the Primary Cause of Automobile Accidents

An international bureau in Geneva forming a part of the League of Nations is analyzing statistics on the causes of automobile accidents. The first series of French statistics has recently been published by the Minister of Public Works and includes accidents throughout France during January of the present year. Although January is not a holiday month, with a large number of private automobiles on the road, there were 319 deaths and 4,164 injured in 3,471 accidents. Of these accidents, 1,371, or nearly 40 per cent, took place in Paris or its suburbs. The largest number occurred during the week end. There were 665 accidents, with fifty-one deaths, on the five Sundays and 586, with sixty-two deaths, on the Mondays; Monday is now a holiday for many people here, as a result of the forty hour a week law. The hurry of automobilists to reach their destination and to return before Tuesday, as well as the lack of knowledge of the roads by some motorists, explains the frequency of these week end accidents. The majority of accidents occurred between 4 and 8 o'clock in the afternoon, the smallest number between 3 and 4 o'clock in the morning. Collisions between motor vehicles and cyclists provide the largest number of fatal accidents. Of 2,275 collisions between motor vehicles of all types and cyclists, 516, with thirty-six deaths, were between passenger automobiles and cyclists and 142, with twenty-deaths, between trucks and cycles. Pedestrians head the list of victims of automobile accidents, with 1,367 injured and 126 killed. The occupants of automobiles, excepting drivers, come next, with 1,055 injured and fifty-two killed. The better the visibility and the better the roads, the greater is the number of accidents, indicating that speeding is responsible. Of the total of 3,471 accidents, 2,246 occurred on straight roads, resulting in 200 deaths. There were 379 accidents, with forty-five deaths, at curves and 585, with twenty-two deaths, where roads crossed.

The Incubation Period of Mumps

Drs. de Lavergne, Kissel and Accoyer, in a paper read at the May 17 meeting of the Académie de Médecine of Paris, reported having found the cerebrospinal fluid of patients in the incubation period of mumps virulent for rabbits. The fluid obtained by lumbar puncture from human beings shows a slight but distinct hypercytosis, from 3.5 to 12 lymphocytes per cubic millimeter. This meningeal reaction could only be found fifteen days after exposure to infection, thus appearing before the onset of the parotitis. The meningeal reaction remains unchanged during the period in which there are already clinical evidences of the infection. In some cases the meningeal reaction remains latent, while in others it gives rise to meningitis either before or after the appearance of the parotitis. The virulence of the cerebrospinal fluid toward rabbits and the hypercytosis of the spinal fluid have almost always been found in human beings exposed to infection who did not present signs of parotitis. This means that these persons exhibit only a meningeal localization and not a parotid one. This explains why, clinically, cases have been observed in which the infection appears only a primary meningitis. In rabbits which have been given injections of the virus into the spinal canal, meningo-

encephalitis not followed by parotitis is always observed. The conclusion reached by the authors is that the occurrence of parotitis is the most typical clinical evidence of an infection by the virus of mumps but not the most reliable or constant sign of such an infection.

Course in Bronchoesophagoscopy by Dr. Chevalier Jackson

Dr. Jean M. Le Mée, in charge of the Otolaryngological Service of the Children's Hospital of Paris, has arranged a course in bronchoesophagoscopy to be given by Dr. Chevalier Jackson, of Philadelphia, and some of his former American and European assistants. The course will begin August 23 and continue until September 1. Lectures and clinical demonstrations will be given in the Blumenthal pavilion of the Children's Hospital and operations on the cadaver at the medical school. Information in regard to the course can be obtained by writing to Dr. Jean Zhâ, assistant in otorhinolaryngology, Hôpital Necker et Enfants-Malades, 149 rue de Sèvres, Paris 15c.

BERLIN

(From Our Regular Correspondent)

May 3, 1938.

Increased Incidence of Rickets

In view of the progress made in recent years in research on vitamin D, it is surprising that an increased incidence of rickets has been reported in Germany and in other countries. This was recently pointed out by the *ordinarius* for pediatrics in Kiel, Prof. E. Rominger. According to several reports, the incidence of rickets among the nurslings of the Westphalian industrial region is between 37 and 46 per cent, and in the city of Dortmund it reaches 55 per cent. From Vienna an incidence of 40 per cent is reported. In the maternal consultation centers in Paris, 40 per cent of nurslings were rachitic. In Basel, Switzerland, the incidence was found to be 75 per cent during the winter and 50 per cent during the summer. Rominger himself gives for Kiel, that is, for a population of Northern Germany, as a conservative estimate 60 per cent for the winter and 40 per cent for the summer; this applies to nurslings who are brought to the clinic for consultation. Of about 1,000 school children in Munich, only 3.5 per cent were found to be free from rickets. Even more surprising are the reports about the increased incidence of rickets in high mountains, in Finland (more especially in fishing districts, in which the population practically lives on fish oil), as well as in the tropics, with the longest and most intensive exposure to sunlight that is possible. Moreover, even in breast-fed nurslings, rickets has been found more frequently in recent years, in Germany occasionally and also in Yugoslavia and in Egypt. A Norwegian investigator even found a high percentage of rachitic infants among those who had nursed at the breast for eight or nine months, and observers on the west coast of Sumatra state that rickets is frequent in spite of the fact that all infants are nursed at the breast.

Rominger believes that he has found the cause for these surprising observations: In the tropics, in Sumatra, the infants are nursed at the breast for a sufficient length of time, but the diet of the mothers is entirely inadequate. To be sure, the intensive sunlight compensates for many defects if the children are really sufficiently exposed to the sun; this, however, is not always the case, because the natives live in pile dwellings, and the young nurslings often remain confined in the house for long periods. In Germany the nutrition of the mothers is generally adequate, but nursing at the breast is not continued for a sufficient length of time; moreover, sufficient natural sunlight is not everywhere available. The conclusion is drawn that every bottle-fed infant requires prophylactic treatment against rickets. The high incidence of rickets in our latitudes can be traced to the fact that the breast feeding of infants is

still not continued for a sufficient length of time and that they are fed too early with a one-sided milk-gruel diet. To be sure, it is possible that only an inadequate quantity of ultra-violet light penetrates the smoke blanket over some industrial cities. Nevertheless, rickets is almost more frequent among the children in rural regions than among the children in cities. Rominger sees the cause in the fact that instructions about this matter reach the city population more readily than the rural population.

Another cause of the frequency of rickets, which is never mentioned, Rominger sees in the inadequate doses of all anti-rachitic remedies. Irradiation with the quartz lamp should not be done now and again but should be done methodically. The doses of vitamin D that are given to bottle-fed infants are usually either too small or are given for too short a time or not regularly. Rominger thinks that there prevails an entirely unjustified fear of excessive doses. With many cod liver oil preparations which have been modified to improve the taste it is necessary to increase the doses in accordance with the lower vitamin D content. It is not enough to prescribe vitamin D or cod liver oil according to a fast rule; the dose must be determined in each individual case, and even for the same child it may have to be temporarily doubled or tripled, for instance, in the course of an infectious disease. In the inadequate and therefore dangerous doses Rominger sees one of the most important causes of the increased incidence of rickets during recent years. The correct dosage cannot be laid down in general rules, and it cannot be left to a lay person. In the prophylactic treatment, especial attention must be given to the right time to begin vitamin D medication in reference to the age, the time of birth and the season of the year; for instance, children born during late summer should receive vitamin D earlier, longer and in larger doses than children born during the winter. Premature infants should receive an especially early and generous prophylactic treatment.

Duration of Pregnancy

The computation of the time of birth heretofore was generally done by the method of Naegele, according to which the period of gestation is computed by counting 280 days from the first day of the last menstrual period. However, the results of a number of new investigations do not quite tally with this figure. For this reason, Dr. K. J. Anselmino, director of the women's clinic of the Rhine province, in Elberfeld, has investigated this problem on a large material. Only those cases were considered in which the labor pains began spontaneously, in which there was an exact record of the first day of the last menstruation and in which the fetus was at least 48 cm. long and weighed 2,800 Gm. With these points in view, 15,000 of the last 25,000 deliveries of the aforementioned clinic qualified for the investigation. It was found that the arithmetical mean of the duration of pregnancy, computed from the first day of the last menstruation, is 282.8, or about 283 days. It is the same for male and female fetuses, but in primiparas it is slightly longer than in multiparas. For this reason it is better for practical purposes to add not seven but ten days after the three months have been subtracted as usual. The term of 282.8 days is a mean value, around which there is a considerable dispersion of individual values. If five days is added to or subtracted from 282 or 283 days, only 43.9 per cent of the women had their delivery within these ten days, whereas more than 25 per cent were not even confined within twenty days, that is, \pm ten days. The determination of the true length of pregnancy, computed from the day of conception, revealed a mean value of 269 days. Since the term of conception is dependent on the length of the cycle, there are in cases of abnormally long or of abnormally short cycles apparent fluctuations in the period of gestation, which must be taken into consideration if the date of birth is computed on the basis of the last menstruation. For this reason the length of the cycle should always be considered

when the date of birth is computed. The formula "minus three months, plus ten days" corresponds to the arithmetical mean of the length of gestation in cases in which there is a twenty-eight day cycle; for the other cycles so many days have to be added to or subtracted from the computed day of delivery, as the cycle in question deviates from the twenty-eight day cycle.

Prof. Erich Hoffmann 70 Years Old

Erich Hoffmann, for many years *ordinarius* for dermatology and venereal diseases in Bonn, celebrated his seventieth birthday April 25. Originally a military physician, he rapidly advanced in a scientific career. After having worked in Berlin and Halle, he became in 1910 director of the dermatologic clinic of the university of Bonn, and as such he held the chair for this specialty. He first became prominent when in 1905 he, together with Schaudinn, demonstrated *Spirochaeta pallida* as the cause of syphilis. He determined the presence of spirochetes in the lymph nodes of patients with acquired as well as with congenital syphilis and described a method of glandular puncture for this purpose. He demonstrated that syphilis can be transmitted by vaccination with syphilitic blood or cerebrospinal fluid. He also made contributions to the development of the therapy of syphilis. Hoffmann published a large number of papers of high merit. When, five years ago, he resigned from his professorship, the activities of this unusually energetic man did not terminate. He continued his research work in the laboratory and made lecture tours; in 1937 he made a trip of several months' duration in response to an invitation from American physicians.

The Annual Medical Congress

The annual medical congress will take place this year in September, by invitation of the Portuguese government, at Lourenço Marques. The congress is held under the auspices of the Medical Association of South Africa and the association is limited to the Union of South Africa. Negotiations between the Portuguese physicians at Lourenço Marques and the association's office at Cape Town easily overcame all organizational difficulties. For purposes of the congress the Lourenço Marques practitioners were all made honorary members of the Association, and the local organizing committee, or rather its honorary secretary and honorary treasurer, Dr. Bostock and Dr. de Carvalho, arranged an interesting program. The president of the congress is Dr. Vasco Palmeirim, senior medical officer of Lourenço Marques, while the patrons are the Portuguese ministers of education and colonies and the governor of the province of Moçambique. The Portuguese government had granted a subsidy to provide for the visit to the congress of professors of the faculties of medicine in Portugal. One problem has been that of providing accommodation for visiting members. Delagoa Bay has limited hotel accommodations and at that time of year it is one of the most popular seaside resorts in South Africa. However, the Italian Steamship Line has agreed to send the luxurious *Duilio*, now running between Cape Town and Genoa, on an excursion cruise to Delagoa Bay to provide not only transportation but accommodation for intending participants in the congress. It is anticipated that the meeting will be one of the most popular that we have had. In 1941 the association will hold a joint congress with the British Medical Association, but arrangements for that meeting have not yet been made.

Dagga Smoking

The use of Indian hemp (*Cannabis sativa*) for narcotic purposes is widespread in South Africa, where it has been prevalent since the days when the plant was introduced from Java at the time of van Riebeeck. Even then, however, it was found that the aborigines smoked a local plant, which they called "dagga." This plant is known botanically as *Leonotis leonurus*,

and it is popular in gardens as an ornamental shrub. Dagga smoking has gradually been replaced by hemp smoking, but the name "dagga" has been used by the police and the public for cannabis. In consequence, confusion has arisen about the effects of real dagga smoking. A report by experts from the mental hospitals has been published in which the effects of hemp smoking are considered, but nothing is said about *leonotis* smoking. The effects of Indian hemp are well known and there is no difference of opinion about their cumulative toxicity, but there is a difference of opinion about the toxic effects of *leonotis*. It is regrettable that the name "dagga," which is historically and botanically applicable to *leonotis* alone, should still be attached to Indian hemp. Dagga smoking is mildly sedative and probably not more harmful to the system than moderate tobacco smoking; cannabis, on the other hand, is definitely a narcotic the use of which should at all events be regulated.

New Hospital on Cecil Rhodes Estate

The new hospital erected on the Cecil Rhodes estate and known as the Groot Skuur Hospital was recently opened and, despite the difficulties of staffing it is already working satisfactorily. So far as planning and construction are concerned, it is most interesting. The architect had to cope with several serious difficulties, among these being the problem of lighting the interior of the hospital buildings and the equally difficult problem of overcoming the effects of windage while providing adequate ventilation. Where the building stands, the southeasterly wind sometimes sweeps down the mountain slopes with a terrific velocity, creating eddies that violently disturb everything with which it comes into contact. The building was originally planned on the pavilion system, which made possible a ready solution of some of these structural difficulties, but the plan was changed to the block system. It is now a seven storied-basement block, providing scheduled accommodation for more than 800 beds, but more patients can be accommodated if necessary. At present some floors are not occupied, as it has been impossible to obtain an adequate nursing staff. The equipment is on the lines of the best American and Continental hospitals. The hospital has been designed as a general hospital. In the children's department, provision has been made for glass cubicles to permit patients with infectious diseases being nursed in the same ward. A paying block is being erected, but it is not clear yet what this addition is to serve. Apart from the fact that there is some doubt about the legality of providing such a paying ward—because the will of Cecil Rhodes prohibits the erection on any part of his estate of buildings designed for profit—there is some misgiving about the desirability of joining a paying ward to a closed institution such as the Groot Skuur Hospital must be, forming as it does the medical and surgical unit of the local university. The profession is perturbed about the innovation, and it is possible that there may be modifications of the present scheme.

Deaths in the Profession

The wastage from deaths in the profession has been considerable. Dr. D. H. Wessels, the foremost gynecologist and obstetrician in South Africa, died suddenly at the age of 56. Dr. A. B. Thomson, one of the pioneers of school medical inspection in the country, died in Natal after a lingering illness; he came to South Africa to organize school medical inspection work in Natal and later went into general practice. Dr. R. B. Thomson, who died in the same week, was the first professor of anatomy at the medical school attached to the University of Cape Town but forsook, for reasons of health, his academic work and retired to a village on the Orange River, where he contented himself with a small private practice. Other deaths during the past few months have been those of Drs. J. Duminy, George Hay, G. Munnik, L. McDowell, O. Heyns and H. N. Everard, all senior practitioners well known in the profession.

Treatment of Rheumatic Disorders

Treatment of rheumatic disorders was the theme of discussion at a recent meeting of the Accademia Medica di Roma over which Prof. Roberto Alessandri presided.

Professor Gosio reported the treatment of rheumatism with intravenous injections of aminopyrine. The intravenous route, he said, permits the action of even small doses of from 100 to 300 mg. He held that treatment with salicylates is still an indispensable therapeutic procedure. The administration of aminopyrine, however, represents a useful and powerful adjuvant, especially for subacute and visceral rheumatism or if the administration of antirheumatic substances by mouth cannot be readily effected. Professor Arcangeli has successfully treated acute rheumatic disorders with salicylate and achieved cure within a few (three or four) days. In addition, he claims that by use of salicylates endocarditis can be prevented, cured or at least palliated and also that pericarditis and myocarditis can be favorably influenced by the same means. To obtain such results, however, it is necessary to administer intravenously, orally or rectally daily doses as high as from 20 to 30 Gm., which may gradually be decreased. By this procedure he has been able also to combat successfully the severe hyperpyrexia that often follows rheumatism and which may be a symptom of endocarditis. Aminopyrine may be usefully employed in treating cerebral rheumatism.

Dr. Poddu observed that it might be interesting to apply the method proposed by Professor Gosio to rheumatic heart disease of the nonfebrile type. The therapeutic efficacy of the method might then be evaluated by successive determinations of the erythrocyte sedimentation rate as well as by the clinical course. According to Professor Pontano, sodium salicylate is of specific therapeutic value in treating acute articular rheumatism, although in his opinion it has no demonstrable effect on concomitant endocarditis. He does not advocate extremely high doses and prefers instead daily administration of from 6 to 8 Gm. on a regular schedule of 1 Gm. every four hours. A sound evaluation of the effect of aminopyrine should result from its experimental use in the treatment of acute forms of rheumatism in children, as the internal organs of children are particularly responsive. Professor Gosio summarized the discussion, which demonstrated, he said, the uncertainties that still surround the specific action of sodium salicylate.

Absence of Dorsal Fixation of Mesentery

Prof. Tommaso Lucherini, of Rome, has studied the absence of dorsal fixation in the differential diagnosis of painful abdominal syndromes. In a report submitted to the Società di Gastroenterologia, he described three cases of absence of fixation of the mesentery, in two of which the failure was complete. One of these cases was characterized by intermittent accessional spasms, referable to the pyloroduodenal region. The attacks tended to come on at meal time, and the symptoms resembled those of duodenal ulcer. The presence of ulcers was not demonstrated by roentgen examination, and symptomatic medical therapy was followed by a measure of success. In the second case the condition began with clinical symptoms of pain referable to the right iliac fossa, which, because of its dull, protracted afebrile development, was suggestive of chronic appendicitis. After roentgenoscopic study, however, such a diagnosis was ruled out. The third case, although the defect was only partial, represented an interesting example of malformation due, according to the author's observations, to a defective rotation of the ansa media; that is, the prearterial descending section (originating in the small intestine) did not rotate, whereas the postarterial descending section (originating in the cecocolon) rotated normally. Roentgen visualization revealed the duodenum free and the small intestine dextroverted, but no inversion of the

long intestine and no ulcerative or inflammatory processes. The patient was periodically seized with pains in the umbilical region, which became violently diffused in the two right quadrants and were often accompanied by emesis. This occurred at intervals of about two months. The attacks would last three or four days and were relieved by administration of belladonna and alkaline substances.

The author concludes that it is impossible to establish a certain clinical diagnosis of defective fixation of the mesentery, since the painful and dyspeptic gastroenteric disturbances which accompany the ectopia are common to many organic lesions of the digestive tract; e. g., ulcers, appendicitis and cholecystitis. Only roentgenoscopic examination permits the sure recognition of the anomaly and then only if every segment of the digestive tract is completely visualized through mediums administered orally and by rectum. Therapeutic approach, aside from symptomatic measures, can be only by surgical intervention. The concomitant complications of absence of fixation, in addition to the morphologic and topographic alteration which facilitates the production of other lesions, are due to the particularly mobile character of the intestinal loops. If painful dyspeptic disturbances are encountered, roentgenoscopic examination is indispensable in the differentiation of intestinal dystopias from disturbances related to nervous and tonic alterations and from organic disturbances of the abdominal viscera.

Systemic Disorders of the Reticuloendothelial System

Professor Dr. Bossa has observed a case of systemic endotheliosis in a man, aged 34, who presented the symptoms of a disorder of the lymphatic system. At necropsy a reaction of the hyperplastic type was evidenced by all the lymphoglandular apparatus and the endothelium of the various lymphatics. The latter appeared macroscopically to be completely infarcted, as if a state of diffuse lymphangitis had existed, related as much to the serous membrane as to the parenchyma. No neoplastic formations were detected in any organs. Microscopic examinations showed that only the endothelium of the lymph nodes and of the lymph sinuses were involved; the normal endothelial line was no longer recognizable, and the entire lumen was occupied by large histiocytes, which showed great polymorphism of the protoplasm and of the nuclei. In reporting the results of his studies to the Accademia della Scienze Mediche e Chirurgiche of Naples, the author discussed the origin of the cells which occupy the lumen of normal lymph vessels and which may be hyperplastic and proliferative, their progressive and regressive aspect, their tendency to form syncytial masses, their manifest phagocytic activity. The study of other cells of the reticuloendothelial system, Kupffer's cells, the perivascular histiocytes and so on, evidenced their perfect integrity; of all these cells, the cells of the serous layer proper also appeared unaltered. The sum of the histologic research data formed a picture of a singular morbid disorder of the endothelial cells of the lymph nodes and of the lymph sinuses. The author proposes that this should be considered as a special form of endotheliosis.

Marriages

JOHN MILTON BARRETT, Greenville, N. C., to Miss Florence Elizabeth Schwartz of Lancaster, Pa., in Baltimore, April 27.

WALDO MASON WATTLES, Farmville, Va., to Miss Lois Wright of Fredericksburg, in Welch, W. Va., April 30.

MAURICE M. ROSENBAUM, Shallotte, N. C., to Miss Kitty Mathias of Wilmington, May 2.

HUBERT RUSSEL HATHAWAY, Madison, Wis., to Miss Lucille Gear of Riverside, Ill., in April.

CHARLES TORBERT BEPPY, Greenville, Miss., to Miss Betty Stevens of Senatobia, April 28.

SAMUEL PARNELL DURR to Miss Dorothy Harker, both of Rock Island, Ill., April 23.

Deaths

Royal Samuel Copeland, United States Senator from New York, died, June 17, at Washington, D. C., aged 69. Senator Copeland was born in Dexter, Mich., Nov. 7, 1868. He received the medical degree from the University of Michigan Homeopathic Medical School, Ann Arbor, in 1889 and later studied abroad. For five years, from 1890 to 1895, he practiced at Bay City, Mich., after serving one year as house surgeon to the University Hospital, Ann Arbor, and as assistant to the professor of ophthalmology and otology at his alma mater from 1889 to 1890. He was professor of ophthalmology from 1895 to 1908. In the latter year he went to New York, where he became dean and professor of ophthalmology at the New York Homeopathic Medical College and Flower Hospital, serving for ten years. Senator Copeland was commissioner of health and president of the New York City board of health from 1918 to 1923. He became United States Senator in 1923, serving until 1929, and was reelected for terms 1929-1935 and 1935-1941. He was mayor of Ann Arbor, president of the board of education and from 1900 to 1908 treasurer of the National Board of Control of the Epworth League. He was a fellow of the American College of Surgeons and a past president of the American Ophthalmological and Otolological Association. Senator Copeland was co-author with A. E. Ibershoff of a textbook "Refraction," 1906, author of "The Health Book," 1924, a "Home Medical Book," 1935, and for many years of a newspaper health column. He received honorary degrees from Lawrence University, Hahnemann College, Philadelphia, Syracuse University, Oglethorpe University and Temple University.

Thomas Lathrop Stedman • New York; College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1877; author of "A Practical Medical Dictionary," which has been widely used in the medical profession and of which the thirteenth edition was published in 1936; editor of the "Twentieth Century Practice of Medicine," and of the "Reference Handbook of the Medical Sciences" and of "The Nurse's Medical Lexicon"; edited other medical dictionaries and handbooks, and contributed to other medical publications; aged 84; died, May 26.

Alleyne Von Schrader • Lieut. Colonel, U. S. Army, retired, Palos Verdes Estates, Calif.; Washington University School of Medicine, St. Louis, 1909; entered the medical corps of the army in 1911; served during the World War; retired as a major in 1920 for disability in line of duty; was promoted to lieutenant colonel in 1930 under a special act; formerly on the visiting staff of the Community Hospital, Long Beach; aged 51; died, March 25.

Harry M. Miley, Chambersburg, Pa.; Medico-Chirurgical College of Philadelphia, 1893; member of the Medical Society of the State of Pennsylvania; veteran of the Spanish-American War; past president of the Medical Society of Franklin County; for many years member of the board of health and formerly health officer; formerly on the staff of the Chambersburg Hospital; aged 73; died, March 17.

Robert B. Campbell, Mount Union, Pa.; Medico-Chirurgical College of Philadelphia, 1895; member of the Medical Society of the State of Pennsylvania; past president of the Huntingdon County Medical Society; president of the school board; aged 73; died, March 17, in the Jefferson Hospital of prostatic hypertrophy and myocarditis.

Charles Ellis Bredt • Mahanoy City, Pa.; Medico-Chirurgical College of Philadelphia, 1908; formerly assistant demonstrator of anatomy at his alma mater; at one time member of the city board of health; on the staff of the Locust Mountain State Hospital, Shenandoah; aged 57; died, March 19.

A. Howard Townsend • Apollo, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1900; past president of the Armstrong County Medical Society; on the staff of the Armstrong County Hospital, Kittanning; aged 63; died, March 12, in the Western Pennsylvania Hospital, Pittsburgh.

William J. Flannery, Brooklyn; Yale University School of Medicine, New Haven, Conn., 1901; member of the Medical Society of the State of New York; formerly associate visiting surgeon to St. Mary's Hospital and St. Catherine's Hospital; aged 61; died, April 19, of carcinoma of the colon.

Edwin Stanley Cooke, Philadelphia; University of Pennsylvania Department of Medicine, Philadelphia, 1888; served during the World War; member of the Medical Society of the State of Pennsylvania; aged 73; died, March 2, in the United States Naval Hospital, of heart disease.

William Alexander Welch • Callao, Mo.; Washington University School of Medicine, St. Louis, 1903; past president of the Macon County Medical Society; formerly county coroner and member of the school board; aged 65; died, March 23, of an infection of the gallbladder.

Frank Foster Sumney, Dravosburg, Pa.; Western Pennsylvania Medical College, Pittsburgh, 1891; member of the Medical Society of the State of Pennsylvania; formerly member of the state legislature; past president of the school board; aged 71; died, March 20.

David Barnes Cooley, Pottstown, Pa.; New York Homeopathic Medical College and Hospital, 1913; member of the Medical Society of the State of Pennsylvania; served during the World War; on the staff of the Homeopathic Hospital; aged 54; died, March 22.

Milton Tighlman McCarty, Frankfort, Ind.; Central College of Physicians and Surgeons, Indianapolis, 1902; city health officer; formerly member of the state legislature; aged 64; died, April 1, of bronchopneumonia, pulmonary fibrosis and esophageal diverticulum.

Samuel Warren Miller, Hamburg, Pa.; University of Colorado School of Medicine, Denver, 1912; member of the Medical Society of the State of Pennsylvania; aged 49; served during the World War; was found dead in March of carbon monoxide poisoning.

Abraham Royden Gregory • Jacksonville, Ill.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1907; at one time assistant in ophthalmology at his alma mater; aged 59; died, April 8, of cerebral hemorrhage and hypertension.

J. Harry Pickle, Millersville, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1891; member of the Medical Society of the State of Pennsylvania; aged 75; died, March 2, of cerebral hemorrhage.

Joseph Richardson Parke, Philadelphia; College of Physicians and Surgeons, Baltimore, 1889; veteran of the Spanish-American War; aged 84; died, March 8, in the Pennsylvania Hospital of injuries received in a fall.

Glendon Franklin Sheppard • Philadelphia; Temple University School of Medicine, Philadelphia, 1923; aged 40; on the staff of the Temple University Hospital, where he died, March 6, of heart disease.

Charles Edmund Ward, Little River, Kan. (licensed in Kansas in 1934); member of the Kansas Medical Society; past president of the Rice County Medical Society; aged 72; died, March 30, of pneumonia.

John Harold Fears • South Bend, Ind.; Ohio Medical University, Columbus, 1903; aged 61; on the staff of the Epworth Hospital, where he died, April 9, of arteriosclerosis, uremia and hypertension.

William Johnson George, Johnstown, Pa.; University of Wooster Medical Department, Cleveland, 1881; member of the Medical Society of the State of Pennsylvania; aged 81; died, March 6, of asthma.

Cooley Baldwin Van Meter • Cincinnati; Miami Medical College, Cincinnati, 1887; for many years examining alienist for the county probate court; aged 76; died, March 17, of arteriosclerosis.

Daniel Frank Gray • Providence, R. I.; Bellevue Hospital Medical College, New York, 1892; on the staff of St. Joseph's Hospital; aged 74; died, April 21, of coronary sclerosis and myocarditis.

Archie Wallace Leech • Beaverdale, Pa.; University of Pennsylvania Department of Medicine, Philadelphia, 1911; for many years postmaster; aged 59; died, March 24, of coronary thrombosis.

Franklin Pierce Herr, Ridgely, Md.; University of Michigan Department of Medicine and Surgery, Ann Arbor, 1878; aged 86; died, March 18, of chronic interstitial nephritis.

Thomas Taylor Kirk • Pittsburgh; Long Island College Hospital, Brooklyn, 1886; aged 77; died, March 16, in the Western Pennsylvania Hospital, of pneumonia.

Stephen Walter Gryczka, Reading, Pa.; Jefferson Medical College of Philadelphia, 1919; aged 49; died, March 6, in St. Joseph's Hospital, of cerebral hemorrhage.

Edward Was, Oostburg, Wis.; Rush Medical College, Chicago, 1884; aged 79; died, March 3, of hypertension and coronary thrombosis.

Henry Surville Holloman, Olla, La.; Memphis (Tenn.) Hospital Medical College, 1900; aged 59; died, April 12, of cerebral thrombosis.

Bureau of Investigation

POW-O-LIN

Another Laxative with a "Kick"

Any one at all familiar with the "patent medicine" industry knows that one of the simplest nostrums to float successfully is a laxative containing enough alcohol to impress its physiologic action on the patient. "Pep 'em up and clean 'em out!" An advertising appropriation is, of course, essential, because the business is highly competitive. But with those requirements met, business can almost be assured.

"Pow-o-lin," or, to give it its full name, "Hamlin's Pow-o-lin," is a comparative newcomer to this market and is put out by the Herb Juice-Penol Company, Inc., of Danville, Va. A Danville newspaper in August 1932 reported that James T. Hamlin Jr. had purchased the Herb Juice Company from Ben J. Lifsey of Jackson, Tenn. It is a question whether this concern really makes the "patent medicine," as the original newspaper story was to the effect that the company's products were manufactured by a pharmaceutical concern in the East and would be shipped in "bulk carload lots for preparation, bottling, labeling and distribution."

The Herb Juice Company had for some years put out a nostrum of the alcohol-laxative type under the name of "Miller's Herb Juice." Incidentally, a little over a year later—November 1933—Jackson, Tenn., newspapers reported that a state charter had been granted the Herb Products Company of that city, which the papers declared was a successor to the old Herb Juice Medicine Company, and the information was added that Mr. Ben J. Lifsey was the president of the corporation. This, however, by the way.

Herb Juice, as already stated, was a "patent medicine" laxative, the trade package of which admitted the presence of 11 per cent of alcohol—presumably the only one of the eleven drugs that the National Food and Drugs Act of 1906 requires to have stated on the label. Pow-o-lin is a "patent medicine" laxative whose carton also admits the presence of 11 per cent of alcohol. Both call for dosages of four tablespoonfuls daily—that is, 2 ounces. As the alcohol content of both preparations is about one-fourth the strength of much whisky on the market, it is easily conceivable that persons not used to alcohol might experience a feeling of well-being after taking a dose of half an ounce of a product of this type.

The present Pow-o-lin seems to be advertised mainly, if not entirely, in the South. The claims on the trade package are quite characteristic of the present day "patent medicine" exploiter. Other than stating that the product is a laxative, about the only claim made is the statement:

"For a condition in which a remedy of this kind is indicated, satisfactory results are guaranteed when taken according to directions."

This is about equivalent to saying that for those who need this sort of thing, this is the sort of thing that such people need!

In the newspaper advertising—which, of course, is not subject to the restrictions of the National Food and Drugs Act—the claims, both direct and inferential, are considerably broader. An advertisement in a Williamsburg, Va., paper details the case of Mr. A. M. Robinson, whose picture appears with his testimonial. According to Mr. Robinson, he suffered from gas pains and nervous indigestion, which he thought were due to "a temporarily clogged intestinal tract that was brought on by my constipated condition."

A Norfolk, Va., paper carried on advertisement of Pow-o-lin with the testimonial (and picture) of Mr. R. P. White. Mr. White, like Mr. Robinson, also suffered from gas pains and nervous indigestion, which, he opined, were due to "a temporarily clogged intestinal tract brought on by neglect of constipation." The similarity of some of the phraseology of these two testimonials might cause a cynical reader to wonder if they had originated in the same advertising agency.

As a number of inquiries have come in from physicians and laymen in the Southern states, asking for information on Pow-o-lin, the Bureau of Investigation obtained an unopened, original package of this "patent medicine" on the open market and

submitted it to the A. M. A. Chemical Laboratory with the request that enough work be done on it to indicate the general character of the nostrum. The Laboratory now reports the following:

LABORATORY REPORT

"One original package of Hamlin's Pow-o-lin (Herb Juice-Penol Co., Danville, Va.) was submitted to the A. M. A. Chemical Laboratory by the Bureau of Investigation. In the trade package there was an eight-ounce flint bottle containing 240 cc. (approximately 8 fluid-ounces) of a light brownish liquid, possessing an odor of licorice. The reaction of the mixture to litmus was neutral. The specific gravity at 25 C. was 1.133.

"No information concerning the composition of Pow-o-lin appeared on either the trade package or the label except the following declaration: 'A Vegetable Preparation . . . Alcohol 11%.'"

"Qualitative tests indicate the presence of an extract appearing to be licorice, a laxative (emodin bearing) drug suggestive of senna, and a sugar which reduced alkaline cupric tartrate solution; traces of sulfate and chlorides were noted. Heavy metals and magnesium sulfate were not found.

"It was concluded that Hamlin's Pow-o-lin is essentially a water-alcohol solution of plant extractives flavored with licorice."

In closing, it is worth noting that on Dec. 23, 1937, the Federal Trade Commission reported that the Herb Juice-Penol Company, Inc., of Danville, Va., had entered into a stipulation with the commission to the effect that Pow-o-lin would no longer be advertised as being "capable of relieving biliousness, nervousness, indigestion and countless ills due to constipation, unless these assertions are limited to temporary relief from constipation."

Correspondence

COLLAPSE THERAPY IN PULMONARY TUBERCULOSIS

To the Editor:—In an editorial comment in THE JOURNAL, May 7, it was viewed with surprise that collapse therapy in pulmonary tuberculosis has not resulted in a greater reduction of the mortality to morbidity ratio in the tuberculosis sanatoriums. It was pointed out that Drolet's recent statistical study showed that the ratio of deaths to new cases varied little throughout various communities during a twenty year period. Lest Drolet's statistics be misconstrued as demonstrating the ineffectiveness of collapse therapy, I should like to offer an explanation for this apparent indictment.

There was published in the January 1935 issue of the *American Review of Tuberculosis* a fifteen year survey of artificial pneumothorax treatment in representative American sanatoriums. The results showed that pneumothorax treatment was given in about 10 per cent of the patients. The authors referred only to cases in which there were at least three months of pneumothorax refills. Cases in which pneumothorax had to be discontinued within three months were not included and were considered as unsuccessful attempts. This means that, a priori, about 90 per cent of the patients in the sanatoriums received no suitable pneumothorax treatment and therefore their ultimate progress was in no way a reflection on this form of treatment.

It was further found that in only 38 per cent of the cases in which artificial pneumothorax was given was an effective collapse maintained (disappearance of symptoms and bacillary sputum and closure of cavities), so that the patients who received an effective collapse were indeed a small percentage of the population of the tuberculosis institutions. It is therefore little surprising that the therapeutic results obtained from about 3 per cent of the hospitalized patients did not appreciably influence the general mortality rate.

While there were other collapse therapy measures used besides pneumothorax, the number of patients who received pneumothorax was far greater than those who had thoracoplasties. Likewise, the number of phrenic nerve operations was not large. It may be concluded that the number of patients given collapse therapy was so small in proportion to the total number of tuberculous patients in the hospitals that it could not alter the mortality statistics even over a period of many years.

Collapse therapy is not applicable to all patients with pulmonary tuberculosis, and the percentage of patients eligible for this form of treatment has therefore been small.

The failure of collapse treatment to reduce the general hospital mortality rates does not detract from the brilliant results obtained in individual instances. These isolated results make little impression on large statistical studies but make a definite impression on the observer. During the past decade many advances have been made. Indications for treatment have been broadened, ineffective pneumothoraces have been converted into effective ones by the Jacobaeus operation, and bilateral pneumothorax has been used more extensively than before. More thoracoplasties are being done throughout the tuberculosis centers with little operative mortality. Last, but not least, is the fact that patients are presenting themselves with earlier lesions more easily suitable for treatment.

The small number of cases acceptable for collapse therapy precludes any reduction of the rate on a large scale. As time goes on the number of cases successfully treated will increase and eventually it will register in the statistics.

MILTON B. ROSENBLATT, M.D., New York.

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

EXAMINATIONS DURING ANTISYPHILITIC THERAPY

To the Editor:—Because of the drive for the eradication of syphilis, I should like to know how often during treatment with bismuth compounds, arsphenamine, neoarsphenamine, tryparsamide and mercury the urine should be analyzed. What are the precautions and contraindications to these drugs as far as can be detected by analysis of the urine? Can you refer me to some literature or give me your experience of the damage that has been produced to the kidneys or other organs when these drugs have been injected and not controlled by urinalysis? Are there other precautions that you advise which the general practitioner should take who is treating or will treat syphilis? How important is the weight and blood pressure? How frequently should the eyes be examined? How often should a Wassermann test or a spinal fluid examination be taken?

P. J. IMPERATO, M.D., Brooklyn.

ANSWER.—The literature covering damage to tissue from the arsphenamines, tryparsamide, bismuth compounds and mercury is an enormous one and is summarized in such textbooks as those of Moore, J. E.: *The Modern Treatment of Syphilis*, Springfield, Ill., C. C. Thomas, 1933, and Stokes, J. H.: *Modern Clinical Syphilology*, ed. 2, Philadelphia, W. B. Saunders Company, 1936.

As far as the kidneys are concerned there is no evidence that the arsphenamines or tryparsamide, when given to persons in good general physical condition, in average therapeutic doses and when grave arsenical reactions such as dermatitis and jaundice are not produced, have any appreciable effect on the blood pressure or kidney function as measured by the phenolsulfonphthalein output or blood chemistry or on the function of other vital organs.

In therapeutic doses, furthermore, neither bismuth nor mercury produces persistent renal damage. Mercury is somewhat more likely than bismuth to cause a mild toxic nephrosis.

With any of the antisyphilitic drugs—arsenicals or heavy metals—there may be transitory albuminuria and cylindruria during treatment, though instances of serious and permanent renal damage which can be definitely and directly attributed to the therapeutic use of these drugs are exceedingly rare.

Many textbooks advise the weekly examination of the urine during arsenical treatment and immediate discontinuance of treatment in the face of mild albuminuria or cylindruria. In actual practice such frequent examinations of the urine may not be necessary, nor may it be essential to abandon treatment in the presence of mild to moderate albuminuria or cylindruria without other evidence of impairment of renal function.

All antisyphilitic drugs and particularly the heavy metals should be used with caution in the face of a previously existing nephritis or nephrosis.

The question concerning other precautions which should be taken by the general practitioner who is engaged in the treatment of syphilis is so generally phrased as to be unanswerable within the limitations of space of this column. The inquirer is advised to consult modern textbooks on the subject of the treatment of syphilis, references to two of which are given.

The weight is an important guide as to drug tolerance and caution should be exercised in antisyphilitic treatment in patients who lose weight rapidly during its progress. Blood pressure is relatively unimportant. Treatment should of course be cautious in the face of severe hypertension, especially if of the malignant variety, and in hypertension due to renal disease.

Repeated examinations of the eyes is unimportant except in the case of tryparsamide.

A blood Wassermann test may be used as a treatment guide in all patients with syphilis and, in general, should be done at the beginning and end of each arsenical course. The details of interpretation of such tests will be found in modern textbooks.

The spinal fluid should be examined in all patients with syphilis; in those with early syphilis at the end of about six months of treatment; in those with late syphilis at the start of or as soon as possible after beginning treatment. If the spinal fluid is abnormal, repeat examinations during treatment are essential.

PREGNANCY IN DUPLICATE UTERINE HORNS

To the Editor:—While performing a vaginal hysterectomy, I found double uteri, complete with tubes and ovaries for each. There was evidence of a pregnancy in each. The patient is the mother of four children. Is this condition unusual or rare?

M.D., Arkansas.

ANSWER.—Partial or complete duplications of the reproductive tract are not uncommon. This is due to the fact that the fallopian tubes, uterus and most of the vagina are derived embryologically from a fusion of the müllerian ducts. The extent of the duplication, therefore, will depend on the extent of the müllerian derivatives that have not fused. A double uterus may or may not be associated with a double vagina. In all cases, however, there are only two fallopian tubes, one arising from each horn. There are rarely more than two ovaries, one on each side.

A pregnancy in each of the two separate horns at the same time is indeed an unusual occurrence. To make this possible two separate ova would have to be fertilized at the same time and each fertilized ovum would have to pass down a separate fallopian tube to the respective uterine horn. Such a condition has been reported in the literature.

ERGOTISM AND RYE BREAD

To the Editor:—I am allergic to both wheat and yeast and as a result consume large quantities of Swedish rye bread and rye crisp. Is there any danger of ergotism?

M.D., Pennsylvania.

ANSWER.—A search of the literature has revealed no reports of ergotism in man in the United States as a result of the consumption of rye bread. Several English papers deal with the subject:

Morgan, M. T.: Report on an Outbreak of Alleged Ergot Poisoning by Rye Bread in Manchester, *J. Hyg.* 29: 51 (April) 1929.

Robertson, James, and Ashby, Hugh T.: Ergot Poisoning Among Rye Bread Consumers, *Brit. M. J.* 1: 302 (Feb. 25) 1928.

Stockman, Ralph: The Cause of Convulsive Ergotism, *J. Hyg.* 34: 235 (June) 1934.

Stockman, Ralph, and Johnston, J. M.: Cereal Food Poisoning and Its Relation to the Etiology of Pellagra, *J. Hyg.* 33: 204 (April) 1933.

Dilling, Walter J., and Kelly, R. E.: Gangrene Following the Use of Ergotized Rye Bread, *Brit. M. J.* 1: 540 (March 31) 1928.

Morgan discusses the agricultural methods employed to prevent a fungous infection of the grain. In his opinion the ergotized grain may be eliminated in the milling process by the use of proper screening and purifying machinery. We have no information about the methods used in this country. It is probable that the United States Department of Agriculture may be able to provide some information relative to this subject.

LILLIPUTIAN HALLUCINATION

To the Editor:—A white man, aged 42, a postal clerk, has complained for the past two years of a feeling of weakness when he is at work. He becomes nervous so that he is unable to write a money order. His sense of dimensions has become distorted, especially of height, and a table 3 feet high appears flattened to about a foot. The attacks last from fifteen minutes to an hour or more. His physical examination is negative except for a slight retraction of the left ear drum. His hearing is good in both ears. The attacks suggest a condition similar to an overdose of insulin.

M.D., New Jersey.

ANSWER.—The attacks, which are incompletely described, suggest a possible aura for a focal lesion in the occipital or temporal lobe of the brain. This lesion may be neoplastic, vascular or inflammatory. A detailed neurologic examination is indicated together with complete ophthalmologic and otologic investigations to include funduscopy, visual fields, and caloric and turning tests. If no focal localizing signs are found it may be necessary to do either a ventriculogram or encephalogram. Neurosurgery is indicated if the lesion is neoplastic or gives any suggestion of it. This type of symptom, that is, defect in dimensions or size, is known as a Lilliputian hallucination. If the lesion is inflammatory or vascular the patient should receive some sedative such as sodium bromide. The weakness, nervousness and inability to write may, on the other hand, be due to some disturbance of the cardiovascular system and not to any cerebral disease.

POSSIBLE HYPERPARATHYROIDISM IN BOY

To the Editor:—A boy, aged 12, heretofore in splendid health, has noticed during the last four months that whenever he gets warm he becomes weak and faint and once he actually lost consciousness. His appetite is poor; he has lost 15 pounds (7 Kg.) in the last three months. During this time he has had three boils on his right hand, something he has never had before. At the beginning of his illness he had some pain around the umbilicus after he ate, which continued for two or three weeks, but since he has been eating less there has been none of this pain. His bowels have moved regularly. Physical examination reveals that he is well developed and nourished, is 5 feet three-fourths inch (154 cm.) tall and weighs 101 pounds (46 Kg.); the weight had been 115 pounds, or 52 Kg., the temperature is 99.2 F. and the blood pressure is 120 systolic and 80 diastolic. Physical examination was essentially negative except for a cardiac rate of 100 and a heart which sounded somewhat overactive. There was a blowing systolic murmur heard at the aortic area when the patient was lying down but not in an erect position. He appeared quite nervous and seemed a little hyperactive. Urinalysis showed a faint trace of albumin. Blood counts were as follows: Nov. 24, 1937, hemoglobin 94 per cent, red blood cells 5,420,000, white blood cells 7,080, polymorphonuclears 60 per cent, lymphocytes 25 per cent, mononuclears 6 per cent, eosinophils 6 per cent, basophils 3 per cent, smear negative; December 17: hemoglobin 95 per cent, red blood cells 5,710,000, white blood cells 9,480, polymorphonuclears 47 per cent, lymphocytes 37 per cent, mononuclears 3 per cent, eosinophils 11 per cent, basophils 2 per cent; December 21: red blood cells 5,130,000, white blood cells 6,800, polymorphonuclears 46 per cent, lymphocytes 44 per cent, mononuclears 3 per cent, eosinophils 7 per cent. X-ray examination of the chest showed marked hilar infiltration but no indication of active tuberculosis. The sedimentation rate was 4 mm. per hour, the basal metabolic rate plus 3 per cent, the fasting blood sugar 83 mg. per hundred cubic centimeters, and the blood calcium 14 and 13.8 mg., tests being taken at an interval of a week. Because of the eosinophil count, three stool examinations have been made by competent laboratory men, without any parasites being found. Do you think this boy might have hyperparathyroidism? The blood calcium content suggests it. There has been no pain which is usually associated with bone changes in parathyroid tumors and, although no roentgenograms have been taken of the long bones, the bony structure of the chest and shoulders appear normal. An active rheumatic infection seems to have been ruled out by the sedimentation rate and the fact that subsequent examinations show a cardiac rate ranging from 72 to 90. Can you suggest any other diagnosis?

M.D., Tennessee.

ANSWER.—Hyperparathyroidism is surely suggested by the blood calcium levels. Blood calcium levels that remain persistently above 11.5 mg. should always be considered abnormal. The principal objection to this diagnosis is in the age of the patient. The age does not preclude such a diagnosis but it speaks strongly against such a possibility. In this case the serum calcium content should be further observed. A persistently high calcium exists for some time preceding the usual symptoms of hyperparathyroidism. A blood phosphorus determination should be made. The combination of high calcium and low phosphorus is extremely suggestive. The plasma phosphatase will be elevated also if there is detectable bone change. The urinary calcium is elevated in hyperparathyroidism but may be elevated also in other disease states. Because of the seriousness of parathyroid tumor, roentgenograms of the long bones should be made. There are detectable bone changes before the typical cysts are formed. Parathyroid tumors are rarely palpable and sometimes are difficult to find at operation. Although the sedimentation rate argues against active infection, a number of possibilities suggest themselves and cannot be lightly discarded. A Mantoux or Pirquet test should be

done. This boy is still within the age limit when hilar tuberculosis is not uncommon. A subacute bacterial endocarditis is a possibility but not a likely one. An infectious mononucleosis should be excluded. The lymphocyte count is scarcely high enough to warrant this diagnosis but a careful differential count and a heterophile antigen test should settle the question. The basal metabolic estimation should be repeated. The heat intolerance, the weight loss, the nervousness and the tachycardia are suggestive of a hyperthyroidism. The search for parasites and ova should be continued.

The fainting attacks, with one actual syncope, raise the suspicion of the effort syndrome or autonomic imbalance. Again the age of the patient makes this unlikely, but such a condition would account for all the symptoms except the hypercalcemia. One may find statements which allege that the white count as given here, that is to say, a normal total count with a relative lymphocytosis, a relative leukopenia and an eosinophilia, is sufficient to warrant such a diagnosis. The diagnosis may be safely made only when the other possibilities are ruled out.

None of these conditions, however, are consistent with persistent hypercalcemia.

WRITERS' CRAMP

To the Editor:—A man, aged 35, an auditor, is facing the loss of his job because of writers' cramp. In addition to the uncontrollable cramp he is bothered with flushing of the thenar and hypotheran eminences of both hands and occasionally slight pain in his right shoulder (he is right handed and does not stammer). His general health is excellent. There is no evidence of focal infection. There is no twitching or wasting of muscles. All laboratory tests are negative. He does not drink or smoke, sleeps well and lives a happy family life. The use of common sedatives and hypnotics has not been helpful.

M.D., California.

ANSWER.—In true writers' cramp there is no difficulty in using the hands for anything except writing with pen or pencil. If there is difficulty with every kind of use of the hands, one must look for neuritis, muscular atrophy, paralysis agitans, tenosynovitis or other organic disease. A person with writers' cramp can use a typewriter without difficulty and should do so as much as possible. If a case is not far advanced, relief may be obtained by teaching the person to write in the correct manner and the use of large cork or rubber pen holders. The cramp is often brought about by gripping the pen tightly and pressing down on the paper with unnecessary force. Attention should also be paid to the light, to the position of the paper and to the height of the desk or table. If a case is far advanced, a period of rest from writing is necessary. After this, care should be taken to observe the rules about proper writing. It is, of course, desirable for victims of this trouble to learn to write with either hand.

DIAGNOSIS OF BRAIN LESION IN CONVULSIVE SEIZURES

To the Editor:—A white man, aged 45, married, a druggist, had a severe convulsion May 16, 1936. Following the convulsion he had attacks, five or more daily, in which he was paralyzed in the left half of the body for about thirty seconds, during which time he had a profound sensation of swelling on the affected side, this sensation being more pronounced in the eye, chest and arm. With the exception of an intermission of two months last summer, he has had from three to five or more attacks daily since the onset. The mental condition of the patient is apparently normal. His weight is stationary, his appetite good and he attends to his work as usual but is nervous and worried because of his condition. The attacks come on quickly after a short prodromal feeling and he has to sit down or catch on something without delay to prevent a fall. Incidentally he has been hurt several times and has had one automobile wreck because of these attacks. Have you any suggestions for diagnosis or treatment?

M.D., South Carolina.

ANSWER.—This patient apparently has an organic disease on the right side of his brain involving the postcentral gyrus and the surrounding brain tissue. The lesion may be a brain tumor, a brain abscess, a cyst involving the cortex and meninges, an inflammatory lesion, a gumma, a syphilitic brain disease or an injury to the right cortex, or the condition may be arteriosclerosis, alcoholism or other less common disorder. The patient should have a neurologic examination, because some signs pointing to a lesion in the right side of the brain will be found. If there is no choking of the disk, an encephalogram should be made to determine the size and location of the lesion by means of ventricular deformity, pineal body shifting and presence of internal and external hydrocephalus. When this is being done a complete examination of the spinal fluid should be made, including manometric measurements to include the pressure of the spinal fluid, the amount of rise of pressure as measured by a manometer from coughing, straining and pressure on each jugular vein, a cell count, globulin determination, Wassermann test and a colloidal gold test. If there is a

choked disk present, a ventriculogram should be made. If the air studies indicate a space-occupying lesion, neurosurgical intervention is indicated for the purpose of exposure and removal of all the lesion that is possible. If the condition is not neurosurgical an anticonvulsant regimen is necessary. This is the giving of sufficient sodium bromide or phenobarbital until the patient becomes free from attacks. When that dose is determined, the patient is kept on it for at least five years. He should not drive a car, swim, climb heights or do anything that is hazardous to himself or to any one else.

OSTEO-ARTHRITIS

To the Editor:—A woman, aged 57, weighing 165 pounds (75 Kg.), past the menopause, began having intermittent attacks of pain along the medial side of the knee joints, first one knee and then the other, six years before I saw her. The attacks until nine months ago never occurred in the two knees at the same time, never lasted more than three weeks and were never severe. She has never received an injury to either knee. The pain never has kept her from work. In April 1937, while she was having sore throat (which was unaccompanied by fever and not sufficiently severe for her to go to bed) she had the same pain in the two knee joints at the same time, much more severe than ever before. She has not been free from pain for a whole day since then. The pain is worse at night and is aggravated when she presses or touches one knee against the other. Walking has little or no influence on the pain. Weather conditions do not influence the pain. When she sits in one position for more than five minutes she has a stiffness in the knee joints with pain on rising, and the pain continues for several minutes until she has walked around for a few minutes and become "limbered up." The condition is gradually getting worse. There is a tender streak along the inner side of the knee joints, running horizontally backward and forward, exactly over the line of the joint. There are no other tender areas about the knee joints, or any other abnormalities. Anteroposterior and lateral roentgenograms of both knee joints show the same condition for the two joints: osseous overgrowth of the inner corners of the knee joints. There is no narrowing of the joint spaces or other evidences of rheumatoid arthritis. No foreign bodies were seen in the picture, which was purposely slightly light for soft tissue detail. Walking does not make the pain worse, nor does standing (she is a schoolteacher). With the leg straight and the knee fixed, outward pulling of the leg causes acute pain at the inner side of both knee joints. The opposite of this, that is, with the knee fixed, and inward pulling of the leg, causes no pain.

L. A. CROWELL JR., M.D., Lincolnton, N. C.

ANSWER:—The case is probably one of osteo-arthritis (senescent) with associated periarticular fibrositis. The cartilage is undoubtedly degenerating and fibrillated but not yet eroded or destroyed sufficiently to permit loss of the joint space. It would be well to have an estimation of the erythrocyte sedimentation rate and a differential blood smear to determine the percentage of nonfilamented cells. In atrophic (rheumatoid) arthritis the sedimentation rate is generally definitely elevated above 20 mm. (one hour) and the incidence of nonfilamented cells is more than 16 per cent. In osteo-arthritis the sedimentation rate is usually normal or nearly normal and the percentage of the nonfilamented cells is often (in 55 per cent of cases) normal.

Osteo-arthritis commonly affects elderly women about the time of the menopause and produces symptoms that may be persistent and progressive or intermittent. Studies by Garvin (1927), Keefer (1933, 1934), Bauer and Bennett (1933, 1934) and others have shown that this type of arthritis affects almost 100 per cent of persons more than 45 or 50 years of age but that only a small percentage have symptoms. The cause of the disease is unknown but it is believed to be a process of age, wear and tear and not primarily the result of infection. The various direct and indirect evidences of infection which are so commonly present in atrophic arthritis are practically always absent in osteo-arthritis.

The symptoms are generally in direct proportion to the amount of trauma endured by affected joints, whether the trauma is that of occupation or obesity or that incident to recreational pursuits. Thus patients who use their joints excessively—laborers, mechanics, farmers, women who do much housework or gardening—may have symptoms, while others may have the disease and yet remain asymptomatic. Symptoms of obese persons develop particularly in weight bearing joints, knees and the lower part of the spinal column. Patients whose threshold for pain has been lowered, by the menopause or otherwise, are more troubled than others. Pain is generally mild or moderate and intermittent. It may be subacute at times. The cause of spells of subacute pain is unknown. Excess trauma usually is blamed, but some believe that a superimposed infection may be responsible, as the case under consideration suggests. Pain in a previously affected but relatively symptomless joint may be produced by an alteration in the mechanics of the joint, by the formation of loose bodies therein, or by the pinching of sensitive synovial villi. Bauer and Bennett (1936) explained the pain thus: When marginal articular tissue is proliferating, the periosteum may become elevated and cause pain; once the marginal osteoid tissue ceases to proliferate and

becomes calcified, pain may also cease. The patient referred to is experiencing "articular jelling"—stiffness after rest, relieved by limbering up. This may be attributable to capsular or periarticular fibrositis, a common accompaniment of osteo-arthritis. Symptoms of periarticular fibrositis often are brought out only, or chiefly, when the articular capsule is put on the stretch. Moderate activity often does not aggravate the symptoms of hypertrophic arthritis; in some cases it apparently does not increase the symptoms but later the joints ache more at night, probably the delayed effect of the day's trauma to joints.

The prognosis is good, although Heberden's nodes may develop on the terminal phalangeal joints of the fingers and hypertrophic arthritis of the midcervical or lower lumbar parts of the spinal column may appear. Osteo-arthritis is not associated with the constitutional reactions (loss of weight, extreme fatigue, anemia), which may become profound in atrophic arthritis. Flexion deformity, ankylosis and serious disability and crippling do not occur. The condition should be considered a nuisance, not a calamity; it should be accepted philosophically as one of the prices of living, one of the minor infirmities of age. It often becomes asymptomatic eventually, and treatment will hasten this stage. The treatment of primary importance is reassurance of the patient that serious disability is not impending. Reduction of trauma by avoidance of unnecessary walking or climbing stairs, by the use of a semielastic support for the knees, the proper type of shoes to avoid knee strain and the avoidance of obesity are imperative. The daily use at home of simple physical therapy (a heat lamp, mild nontraumatizing exercises) gives considerable relief. Roentgen therapy provides analgesia in some, but not in all, cases. Vaccines, special diets, sulfur and gold salts are apparently valueless. Obvious foci of infection which can readily be removed should be removed; others should be left alone.

SKIN STAINING FROM DIPICRYLAMINE

To the Editor:—Please give me information on the treatment of skin discoloration with dipicrylamine powder. A laboratory worker was exposed to this substance five months ago.

CLIFFORD F. LEET, M.D., Horseheads, N. Y.

ANSWER:—The fact that the skin has remained stained for more than five months argues that the chemical penetrated the epidermis and reached the deeper structures of the skin. A stain that affects only the epidermis will fade gradually and disappear.

Some substances are capable of penetrating the epidermis and in effect tattooing the skin. Such materials generally have to be used over an extended period of time and rubbed into the parts. Thus, Goeckerman reported permanent darkening of the skin from metallic substances in cosmetics which became deposited in the skin after years of usage.

If the chemical which becomes anchored in the lower layers of the skin has the property of darkening on standing, its staining of the skin may be expected to deepen in time. Some aminophenols, of the class such as the offending agent under consideration, may darken on exposure to air and light and thus intensify the stain of the skin in which they are fixed after a time.

The problem of its removal is akin to that of ordinary tattooings. The use of carbon dioxide snow might be attempted on a small patch, but this method hardly lends itself for use over a large area. This subject was discussed in *THE JOURNAL*, June 18, page 2100.

PHOSPHATE AND URATE KIDNEY STONES

To the Editor:—A white man, aged 32, during the last six years has had three small renal calculi, visualized by x-ray examination and small enough to have been passed through the ureters and the urethra. Although he has been drinking ten or twelve glasses of water daily, the urine always shows a large deposit of crystals. The deposit appears to be about the same quantity whether the urine is acid or alkaline. Two of the calculi have been of phosphate composition and one of urate. He has been on a low purine and low mineral diet at various times without any apparent change in the amount of crystalline deposit in the urine. The condition is complicated by a chronic nonspecific prostatitis, at times acute, apparently after an upper respiratory infection, which has responded on two occasions to sulfanilamide therapy. On large doses of vitamin A there has been no change in the urine. The renal function as tested by dye excretion, concentration test and blood chemistry is normal. The blood calcium and phosphorus levels are also normal. The urine obtained by ureteral catheterization has been free from pus. Is there likely to be any relationship between the chronic prostatitis and the formation of the renal calculi? Is there any dietary regimen which might prevent the excretion of the large amounts of crystalline material?

ALEXANDER G. SILBERSTEIN, M.D., New York.

ANSWER:—In view of the fact that the calculi have been of phosphate composition and also of urate composition on one occasion, the continued use of an acid-ash diet with a low purine content would be advisable. This dietary regimen will probably reduce the amount of crystalline deposit in the urine

Book Notices

Fifty Years a Country Doctor. By William N. Macartney, M.D. Cloth. Price \$3.50. Pp. 584, with portrait. New York: E. P. Dutton & Company, Inc., 1938.

This is the story of a doctor who began life in a small town in New York on the St. Lawrence River, got his preliminary education in the schools of the town, went to medical school for two years in New York City, had an internship in Bellevue Hospital, and then went back to his home to practice in order to be with his parents in their old age. Eight years later, when they had died and he had accumulated enough to cover the lean years that he would have in establishing himself in New York City, where it was his original ambition to practice, he went back there, looked around long enough to decide that to practice in Fort Covington, among the people he knew, was his choice, went back home and has devoted the last forty years to practice there. He graduated in 1888. The town had a population of 600 then; in 1936 it had a population of 764, so this is the story of a real country doctor. It is a story also of a vigorous mind, alert, quick, independent. The book describes a fine life. He is a sympathetic man, but the book has no sob-stuff. It is full of interesting episodes with many good stories—told briefly—and vivid accounts of practical experiences in taking care of difficult emergencies, usually alone.

After a good chapter on his youth, the next chapters are devoted to his experiences at medical college and at Bellevue. It happens that the reviewer was a member of the same class in the same medical school, and he can testify to the accuracy of the descriptions of conditions. The brief sketches of the members of the faculty are by one who has more than the ordinary capacity for hitting off the characteristics of men and make one more inclined to take at their face value all of the later statements. Once in a while, however, a mistake is found, as when, apropos the blizzard in New York in 1888, he said "In those days we had no weather bureau" (p. 37).

The next seventeen chapters are short—as are all the chapters in the book—and are devoted to the general topics that concern the doctor, particularly the country doctor: beginning in practice, advances in technic, characteristics of patients, fees, the dead beat and things of that sort. They are full of worldly wisdom, in the best sense of that term, that has been matured by long experience in a busy important life. The remainder of the book is devoted to consideration of the common diseases and contains many acute observations and wise practical suggestions.

He is a cheerful soul and must have enjoyed life. His style is sprightly, he writes good clear English, and the book is entertaining reading. It is a fine exposition of the attractiveness of a country practice to a competent man. The first fifteen chapters, only 135 pages of easy reading, ought to be read by all senior medical students.

Lettres à un jeune praticien sur les maladies de l'anus et du rectum. Par Roger Savignac. Préface du Professeur A. Gosset. Paper. Price, 26 francs. Pp. 129. Paris: Masson & Cie, 1937.

The author's plan of presentation in this book is indeed unique. Presumably he has been asked by a young doctor for his advice and experience relative to the more common anorectal diseases. Savignac's background is a twenty year period of service as director of the proctologic clinic of the Salpêtrière. He makes his contributions to the "young practitioner" in the form of a series of letters, fourteen in all, each one covering a specific subject. The work serves admirably first to make the practitioner conscious of anorectal disease and then to instruct him in the performance of a thorough examination, both digital and endoscopic. The author considers his patient to have a serious ailment until such has been ruled out by thorough investigation. He has placed proper emphasis on the serious nature of chronic ulcerative colitis and of inflammatory rectal stricture. With regard to the etiology of the latter entity he feels that our present conception is still hypothetical. The author has purposely avoided discussion of surgical technic other than that pertaining to the agents of physical therapy such as medical and surgical diathermy. As a result, so much emphasis is placed on the ambulatory or office treatment of hemorrhoids,

fissures and fistulas that the work smacks a bit of the "ambulant proctologist." One cannot help but fear that the young doctor will be led to place too much faith in nonsurgical methods and that he may not be brought to realize the full significance of anorectal infections. No one cares for unnecessary surgical procedures. However, most patients suffering from fissures, fistulas or complicated piles are deserving of hospitalization for proper surgical treatment. The sections on fissure and fistula are at once both pleasing and disappointing. With regard to anal fissure the author advocates three forms of treatment: electricity (diathermy), local injections and dilation under anesthesia. Anal abrasions might be amenable to such therapeutic endeavors, but true anal fissures, in the experience of well trained proctologists, yield only to proper surgical treatment fortified by thorough and persistent after-care. In his "letter" on anal fistula the author emphasizes surgery as the only adequate form of treatment. However, when mention is made of "blind" fistulas, of injections of methylene blue to facilitate visualization of the tract, and of x-ray studies after injection of colloidal thorium dioxide or of iodized oil one cannot help but feel that the author does not possess a full conception of the pathogenesis of fistula-in-ano. The final letter is a brief review of the causes of "anorectal" hemorrhage in the order of their frequency and significance. The book is a valuable addition to the literature of diseases of the anorectum and colon. It should be read by the general practitioner, by the gastrointestinal internist, by the general surgeon and by the rectal surgeon.

Physical Exercises for Asthma. Approved by the Honorary Medical Advisory Committee of the Asthma Research Council. Second edition. Paper. Price, 1s. Pp. 32, with illustrations. London: Asthma Research Council, King's College, 1937.

The brochure is written for the layman as well as for the physician. The purpose of the exercises described, as stated in the introduction, is to correct the shortening of the muscles of respiration which occurs in asthma. The contraction of these muscles produces the "barrel-shape" chest. Because of this the lungs remain distended even when the patient is free from attacks. In early cases the purpose is to prevent such occurrence. In chronic cases the attempt is to restore the chest cavity and lungs to normal size. In asthma the tendency is to breathe almost entirely with the upper part of the chest, the lower part of the chest remaining relatively immobile. The diaphragm moves little. The exercises are aimed to teach the patient "diaphragmatic breathing," to use the abdomen and lower part of the chest as well as the upper part of the chest. Three groups of exercises are described. Each is simply explained and adequately illustrated by reproductions of photographs. There are five elementary exercises, five advanced exercises and four children's exercises. While each is intended to exercise a different group of muscles, the breathing principle is the same in all—a short inspiration through the nose, followed by a gentle, prolonged expiration through the mouth. During the expiration the patient makes an F or S sound with the lips or teeth to fix his attention on blowing out as long as possible. During inspiration the upper part of the chest must remain still, the abdominal wall rising during this phase. With expiration the abdominal wall contracts slowly. It is recommended that exercises be practiced for at least ten minutes twice a day. The value of exercises as an adjunct in the treatment of asthma has been recognized for many years. As pointed out in this pamphlet, they should, however, be supervised at the start by a trained person. While these exercises can be of help, they will be sure to fail unless the physician or a trained gymnast supervises them until the patient does them correctly.

Sixteenth Hospital Yearbook. 1938 Hospital Purchasing File: Directory of Products, Manufacturers' Catalogs, Purchasing and Other Reference Data. Boards. Price, \$2.50. Pp. 838, with illustrations. Chicago, Illinois: Modern Hospital Publishing Co., Inc., 1938.

This book is a standard reference on hospital buying. It contains extensive catalogues on clinical and scientific apparatus, general furnishings, food service equipment, laundry supplies and construction materials. To hospital executives it also presents a valuable section on purchasing and other reference data relative to the planning of ward and private services, surgical facilities, outpatient, maternity, pediatric and psychiatric departments, the tuberculosis unit, contagious disease wards, x-ray and physical therapy departments, laboratories,

the nurses' home, the school of nursing, kitchens and the hospital laundry. Special articles give authoritative information on the quality and performance of hospital equipment and supplies and should be of distinct value to purchasing agents. There is a useful description of typical hospital positions, a list of state, sectional and Canadian hospital associations, current hospital statistics, per capita costs and occupancy figures. The administrative departments of hospitals will find the Yearbook a valuable source of reference. Its use is enhanced considerably by a convenient index of catalogues and advertisements, a directory of hospital products covering 217 pages, a guide to purchasing and other reference data, and useful check lists of departmental equipment and supplies.

Untersuchungen über die Augenhöhlen des Menschen in verschiedenen Lebensaltern. Von Per Pallin, Med. Lic. Inauguraldissertation welche mit gehöhriger Genehmigung der weltverfahrenen mediznischen Fakultät zu Uppsala verteidigt wird. Sonderabdruck aus Acta Societatis medicorum Suecane Bd. LXIII, 1937. Paper. Pp. 107, with 22 illustrations. Stockholm: Isaac Marcus Boktryckeri-Aktiebolag, 1937.

In this dissertation from the University of Uppsala, produced under the direction of Professor Berg, ophthalmologist, and Professor Agduhr, histologist, Pallin investigates the evolution of the orbit from fetal to adult life. Ample material at various ages has been systematically analyzed according to accepted modern biometric procedure, and the data provided should facilitate a better visualization of the mechanism of orbital development. At the beginning of the second month of embryonic life the eyes look laterally, reminiscent of our phylogenetic ancestry, and the optic stalks are in line with each other. The angle is reduced to 105 degrees in the next month, reaches 71 degrees at birth, and converges from 3 to 5 degrees further by maturity. In late childhood the expansion of the facial skeleton increases the orbital and interorbital width much more than the distance between the optic foramina, occasioning consequently a forward divergence of the orbital axes and of the associated cone of ocular muscles. In this connection the author seriously considers the contention made by Weiss forty-five years ago that this developmental process accounts for the occasional spontaneous correction after puberty of low degrees of convergent squint but fails to discuss the various other anatomic and physiologic factors to be considered. In view of these changing relations of the orbit from birth to maturity, the associated changes involved in maintaining parallel vision is an interesting inquiry that should repay further study.

The Basis of Tissue Evolution and Pathogenesis. By Albert A. Gray, M.D., F.R.S.E. Cloth. Price, 7s. 6d. Pp. 92, with 12 illustrations. Glasgow: Jackson, Son & Company, 1937.

Those who are conversant with Albert A. Gray's large and comprehensive two volume work on "The Labyrinth of Animals" will little wonder that this clinician and investigator should subsequently be writing on problems pertaining to evolution. His extensive studies on the comparative anatomy of the intricate and delicate inner ear naturally led Gray to ponder over the problems of origin and variation. Then too his observations and contributions in the field of clinical otology, especially otosclerosis, afforded opportunity for reflection in the field of pathogenesis. Whether or not entirely in accord with the concept of Gray on tissue evolution and pathogenesis, one cannot but admire him for his spirit and industry in subjecting his clinical problems to scientific laboratory scrutiny.

From the beginning, Gray appears to have given thought to the manner in which the structure of plants and animals may have evolved in direct relationship to environment. He had intended to publish a book giving his matured views on this subject but died before this could be fully consummated. Fortunately he left a manuscript, and his younger son, conversant with the subject matter, assumed the responsibility for publishing posthumously his father's last work.

After the foreword, the book is divided into four parts, on the basis of tissue evolution and pathogenesis, evolution of the tissues, repair, and evolution of tissues and structures. At the outset Gray deprecates the narrow view of pathogenesis often held, aptly saying that in all pathologic processes there is present a soil and a seed. He holds to the concept that disease processes are merely one manifestation of biologic processes and that they cannot be considered apart from the ordinary problems of biology. When he speaks of an injuring agent, he has in mind

the environment of the organism or tissue. The point is made that the direct observation of the behavior of a tissue toward an injuring agent and its evolutionary fate must be impossible at all times, since the process itself must extend over vast periods. Gray here speculates "upon the evolution of the tissues, using as a basis the accumulated knowledge of biological and pathological processes, and particularly the process of repair in living tissue." He appreciates that "from the very nature of such problems, some amount of speculation is absolutely necessary" but says that "even then it will be possible to bring considerable evidence from observed facts in support of the views advanced."

Gray feels that the process of repair acquires a very real biologic significance, quite apart from the usual teleologic explanation so widely accepted. He suggests that the change in the character of a given tissue, the metaplasia, is the basis of the evolution of species and is a fundamental factor in pathogenesis. He would substitute the concept of "induced variation" for the doctrine of "spontaneous evolution." He makes much of injury, that is, environment, and the fact that ultimately environmental factors may lead to fixed and new conditions of tissues, with even a heritable tendency. He attempts to correlate his hypothetical concepts with his daily clinical problems.

In the foreword of the book, the wish is expressed that those who read its pages will do so with insight and imagination. The volume merits reading.

Theoretical Principles of Roentgen Therapy. Edited by Ernest A. Pohle, M.D., Ph.D., F.A.C.R., Professor of Radiology, University of Wisconsin, Madison. Foreword by W. Edward Chamberlain, D.S., M.D., F.A.C.R., Professor of Radiology in the Temple University School of Medicine, Philadelphia, Pa. Cloth. Price, \$4.50. Pp. 271, with 132 illustrations. Philadelphia: Lea & Febiger, 1938.

This book is a collective work. The demand for knowledge of the physical, chemical and biologic basis of roentgenology has increased. The physics of x-rays by Stenstrom Newell provides a review of the various aspects of therapeutic x-ray equipment; he describes the instruments for calibration (tubes, filters and other materials necessary for roentgen treatment, such as tables, control stands and the proper choice of space). Taylor and Pohle consider dosimetry. Superficial and depth doses and the relation to the percentage volume are distinctly treated, and the difference in their application is described. The importance of a definite plan of treatment is well developed. In a further chapter, Ward discusses radiology and radiopathology; that is, the reaction of cells, skin, tissue, blood and internal organs to the x-rays. Finally, Taylor develops the idea of the tolerance dose and protection from the x-rays. The recommendations of the Advisory Committee on X-Ray and Radium Protection have been copied verbatim.

An Atlas of Gas Poisoning. Reprinted by the Home Office (Air Raid Precautions Department). Second edition. Paper. Price, 35 cents. Pp. 16, with 11 illustrations. New York: British Library of Information; London: His Majesty's Stationery Office, 1937.

This booklet is one of a number of excellent handbooks and pamphlets issued by the home office of the British government, presenting various phases of warfare as it may affect the civilian population and intended primarily for civilian use. From its rather broad title one would perhaps expect a more comprehensive treatment of the subject, for, with the exception of a single plate depicting a rare case of thrombotic gangrene of the foot following chlorine poisoning, the pamphlet confines itself to the effects of but two warfare agents, phosgene and mustard. Presenting these, however, as respectively representing pulmonary irritants and vesicants—the two classes of chemical warfare agents used primarily for the production of casualties among personnel—the atlas handles them well: ten colored plates, three relating to phosgene and seven to mustard, picture the principal clinical and pathologic effects of these two agents; and the accompanying descriptive text is clear and concise. The pamphlet is a second edition, the first having been published in 1918 for use by medical officers serving with the British Expeditionary Force. As stated in the foreword, the present edition reproduces substantially the same text and drawings as the first edition, with minor textual revisions in the light of later knowledge; and its primary aim is that of general instruction for doctors not already familiar with the subject. Toward this end, the atlas is an authoritative and valuable help.

Précis de chimie organique. Par Victor Grignard, membre de l'Institut (prix Nobel). Publié par les soins de Roger Grignard, ingénieur-chimiste E.C.I.L., préparateur à la Faculté des sciences de Lyon, et Jean Colonge, ingénieur-docteur, chef de travaux à la Faculté des sciences de Lyon. Préface de M. le Professeur G. Urbain, membre de l'Institut. Cloth. Price, 175 francs. Pp. 774. Paris: Masson & Cie, 1937.

Victor Grignard, Nobel laureate, commands such respect among organic chemists that anything bearing his name must be treated with more than ordinary consideration. It is true that this book is posthumous, but it is completed as a token of respect and veneration. One would expect, therefore, and finds, unusual care and precision in the work. It is stated in the introduction that the book reproduces faithfully the course given by Victor Grignard, each year, to candidates for the certificate of general chemistry in the School of Industrial Chemistry at Lyons. It is therefore a textbook the worth of which is proved. Organic chemistry is a subject as logical as geometry. No unusual order of presentation is to be expected or found. The order is much the same as is found in standard textbooks. Following a chapter on general fundamental principles, the following plan is followed: aliphatic and cyclic hydrocarbons, organic metallic compounds, alcohols, phenols, thioalcohols and thiophenols, aldehydes, ketones, sugars, cetenes, acids, amines, albuminoids, nitrils, amides, heterogenic cyclic compounds. The treatment is strictly scientific. When such subjects as ethylene and cyclopropane are discussed, no mention is made of their uses in anesthesia. Quinine, he states, has been used as a febrifuge since the seventeenth century, the historical fact apparently, and not the practical use, being the more interesting. The book is written with a clearness to which the French language lends itself, but even as a French work the clearness of expression is notable. It is an excellent textbook and is an honor to the memory of a man who needs no added eulogy.

Report on Progress of the Works Program December 1937. Harry L. Hopkins, Administrator, Corrington Gill, Assistant Administrator, and Emerson Ross, Director, Division of Research, Statistics and Records. Paper. Pp. 112, with illustrations. Washington, D. C.: Works Progress Administration, 1938.

Nearly \$9,000,000,000 had been distributed up to Oct. 31, 1937, which at the maximum gave relief in the form of work to more than 3,000,000 persons. Projects, which were approved in all cases by local authorities, include highways, public buildings, parks, conservation, airports and a wide variety of "white collar" and educational activities. Special mention is made of the Carrie Tingley Hospital for Crippled Children at Hot Springs, N. M., the Milwaukee Sewing Project, which during the six months from April through September 1937 produced more than 840,000 garments, and various public works. A sample of 1,595,000 workers in August 1937 showed that 64 per cent of them were unskilled and only 5 per cent professional and technical workers. The National Youth Administration, by the expenditure of \$122,233,050 in 1936 and 1937 aided 400,000 youths each year in obtaining an education. Various research projects, especially some in regard to the effects of technologic development, were conducted.

Chiropody: Theory and Practice. By Franklin Charlesworth, F.B.A.Ch., Founder of the British Association of Chiropodists. Foreword by W. Sayle Creer, M.Ch., F.R.C.S. Second edition. Cloth. Price, 15s. Pp. 205, with 57 illustrations. London: Actinic Press, Ltd., 1938.

The first part of the book is a review of the anatomic structures of interest to the chiropodist. The author warns the chiropodist that many of the conditions which the latter is called on to treat can be successfully handled only by a qualified surgeon. The writer of the foreword to the first edition calls attention to the fact that modern fashions in footwear and over-indulgence or carelessness in the pursuit of various sports have increased the frequency of foot complaints. There is today a large number of persons who are attempting, with and without training or qualification, to deal with them. The manuscript has been reviewed, read and corrected by an orthopedic surgeon. Chapters on the anatomy and physiology of the foot and lower part of the leg are given in some detail in order to lay the groundwork for the second part of the book. The author discusses osteology, connective tissues, ligaments of the knee, ankle and foot, muscles of the leg and foot and arteries and veins of the leg and foot, and the nervous system. Some of

the conditions mentioned are taken care of by little more than a definition, which is just about all the space they deserve in this type of book. The information appears to be accurate, much of it having been taken from other sources of anatomy and physiology. The chapter on foot orthopedics is satisfactory. The chapter on pads and domes and strappings is good. The chapter on ringworm of the foot is weak. If the author had used the space occupied by the respiratory condition for elaboration of the treatment of ringworm—which is so common and important—it would have enhanced the value of the book. The case notes from the foot hospital are commendable.

Introduction and Guide to the Study of Histology for Students in Medical Schools and Colleges. By Avery E. Lambert, Ph.D., Professor of Histology in the School of Medicine, State University of Iowa. Cloth. Price, \$5. Pp. 542, with 185 illustrations. Philadelphia: P. Blakiston's Son & Co., Inc., 1938.

The descriptive matter of this book is written from the point of view of the older textbooks and is based on the data they contain. Most of the illustrations are the well known semidiagrammatic figures of Stöhr, to which a few original photomicrographs and some illustrations from recent textbooks have been added. The work is prefaced with a simple description of the compound microscope and directions for its use. The text is interlarded with detailed directions for the study and drawing of the prepared sections furnished. The author does not regard the study of fresh tissue as practicable for beginners. There is an appended list of titles for the student who may have been inspired to seek further information.

Grundlagen der allgemeinen und speziellen Arzneiverordnung. Von Paul Trendelenburg. Herausgegeben von Otto Krayer, Professor der Pharmakologie an der Amerikanischen Universität Beirut (Libanon). Fourth edition. Paper. Price, 16.20 marks. Pp. 322. Berlin: F. C. W. Vogel, 1938.

The first part of this book (twenty-eight pages) deals briefly with the general technic of medication, the remainder (almost 300 pages) with the special technics. In the second part are discussed with practical detail and under a therapeutic classification the technic of prescribing and administering the important medicinal substances. The author intentionally avoids all theory as well as all discussion of the nature and mode of action of the various bodies under discussion. He describes, on the other hand, in practical detail the nature of the remedies and their indications, untoward effects and dangers, as well as methods of giving them, including numerous illustrative prescriptions. In a book dealing so extensively with the administration of medicines, it is to be regretted that so little attention is paid to elegant or palatable medication.

Néphropathies et néphrites. Leçons cliniques (1934-1936). Par F. Rathery, professeur de clinique thérapeutique médicale à la Faculté de médecine de Paris. [2^{me} série.] Paper. Price, 60 francs. Pp. 356, with 30 illustrations. Paris: Librairie J. B. Baillière et fils, 1937.

This volume is a second series of clinical lectures embracing material similar to that in the former volume by the same author. The cases presented are all interesting and for the most part unusual or frankly rare. The prolixity and repetition inherent in the presentation of clinical lectures perhaps unnecessarily lengthens some of the chapters. Nevertheless the accounts of the cases are enlivened by the engaging language of Professor Rathery. The lectures open with a discussion of classification of nephritis and the author offers what he is pleased to term a "functional" classification, wherein kidney lesions are divided into nephropathies and nephritides, the former group showing evidence clinically or pathologically of renal alteration without accompanying functional impairment while the latter group embraces renal lesions which show functional changes with or without superimposed evidences of the play of bodily compensatory mechanisms. The classification is novel but, like all others, is too circumscribed and leaves much to be desired. Case studies include purpuric nephritis, chronic azotemic and hypochloremic nephritis secondary to a unilateral renal lesion, renal acidosis, renal forms of endocarditis lenta, various types of "nephrosis," lead and mercurial nephritis, hepatonephritis, gouty kidney, nephritis secondary to lithiasis and finally renal dwarfism. The cases presented were for the most part well studied and a great many were proved at the necropsy table or from biopsy specimens procured during

the course of surgical procedures. The author's discussion is interesting and in general accord with modern theory. Nevertheless, several of the conclusions which the author sets forth are difficult to rationalize with the stated facts in the particular case, while many of his conclusions are frankly confusing. In general the volume has reading interest for the specialist in the field of renal disease, although some of the case reviews are of such a nature as to attract internists directing their attention to metabolic or hepatic diseases.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts: Rupture of Aneurysm Resulting from Strain.—Evans had not performed any manual work for four months. He was employed by the defendant to repair road scrapers, tightening bolts and boring holes with a five-eighths inch bit through 4 inch timbers. After working for twenty minutes, Evans complained of a severe pain in his abdomen and sought water and sodium bicarbonate, which he obtained at a farm house about 75 yards away. At that time he was not vomiting but "looked kind of pale as if he were in great pain," and had beads of sweat on his face. He collapsed and died within ten minutes. The physician who was called believed at first that death was due to either acute gastritis or heart trouble. An undertaker, however, in the course of embalming the body, inserted a trocar into the abdominal cavity and withdrew a quart and a half or more of blood. The physician who had been called did not learn of this until after the body had been buried, and then he concluded that death resulted from a ruptured aneurysm of the aorta, of a mesenteric artery, of the hepatic artery, or of a renal artery.

Evans' widow brought proceedings under the Idaho workmen's compensation act. The physician who had viewed the body gave his opinion as to the cause of death as stated above. Another physician, called on behalf of the widow, in response to a hypothetical question in which was given the substance of the testimony showing the symptoms presented by the deceased workman, the nature of his work immediately prior to death and the finding of blood in the abdomen, testified that Evans died of a ruptured aneurysm in the upper abdominal cavity, the rupture being due to "the increase in blood pressure due to exertion of working with the brace and bit." Another physician, however, called on behalf of the employer and his insurance carrier, testified that he had heard the testimony of the witnesses and that in his opinion the most probable cause of Evans' death was coronary disease. The cross examination of this witness indicated that in forming his opinion he did not accept the statement of the undertaker as true; he apparently did not believe the undertaker would know blood if he saw it, nor that he knew from what cavity or cavities in the body he drew it. The industrial accident board held that Evans' death was due to disease and was not the result of any injury arising out of and in the course of his employment. The district court, Oneida County, reversed the order of the industrial accident board denying compensation, and the employer and his insurance carrier appealed to the Supreme Court of Idaho.

There is no conflict, said the Supreme Court of Idaho, in the evidence in this case other than in the testimony of medical experts. The testimony of an expert as to his opinion is not evidence of a fact in dispute. It is advisory only, to assist the triers of fact to understand and apply the testimony of other witnesses. Its value depends on, among other things, the expert's confining his testimony to the facts incorporated in the question propounded to him and, if he does not assume those facts to be true and base his answer on them, his testimony is worthless and should be rejected. It is for the triers of fact to determine whether the evidence on which the expert

bases his opinion is true or not. It is not for the expert to determine the truth or falsity—the reliability or unreliability—of the testimony of other witnesses. For that reason he should not be asked to base his opinion on the testimony of other witnesses which he has heard, but the facts which that testimony tends to establish and which is relied on by the party propounding the question should be hypothetically stated. The testimony of the expert should be responsive to that hypothetical question and it is his duty to assume facts embraced in the hypothetical question to be true.

The court accordingly concluded that the testimony of the physician called by the employer that the most probable cause of Evans' death was a coronary disease and that he did not hear any evidence presented in the case that would indicate to him that death resulted from a ruptured aneurysm was not entitled to be given weight and should be rejected. That testimony being eliminated, continued the Supreme Court, the remaining evidence was amply sufficient to establish that Evans died from a ruptured aneurysm due to increased blood pressure caused by the exertion required by the performance of the duties of his employment and his widow was entitled to compensation.—*Evans v. Cavanagh (Idaho)*, 73 P. (2d) 83.

Taxes: Credit Association Composed in Part of Physicians Not Exempt from Taxation.—The Retailers Credit Association, a corporation organized under the laws of California, included in its membership physicians, dentists and other professional men. Among its various activities, it furnished reports on the credit rating of individuals to members, for which service a fee was charged. It also acted as a collection agency for members, receiving a commission for so doing. Its activities normally resulted in a profit and, while the by-laws provided for the payment of dividends to members under certain circumstances, no such payment had ever been made.

For the year 1931 the corporation had a net profit of \$6,000. It claimed exemption from the payment of federal income taxes for that year on the ground that it was a business league within the meaning of the Revenue Act of 1928, which exempted "business leagues . . . not organized for profit and no part of the net earnings of which inures to the benefit of any private shareholder or individual." A denial of the claim for exemption was affirmed by the board of tax appeals (33 B. T. A. 1166), and the corporation appealed to the circuit court of appeals, ninth circuit.

Under the federal income tax regulations, said the court, a business league to be exempt must not engage in a regular business of a kind ordinarily carried on for profit. While the court thought that the Retailers Credit Association was a "business league" within the meaning of the income tax law, it seemed clear that one of its purposes was to engage in a regular business of a kind ordinarily carried on for profit, namely, the credit reporting aspect of its service and its collection activities, and that these activities were not incidental to the main purposes of the corporation but were primary purposes. The court therefore affirmed the ruling of the board of tax appeals denying exemption to the corporation.—*Retailers Credit Assn. of Alameda County v. Commissioner of Internal Revenue*, 90 F. (2d) 47.

COMING MEETINGS

- American Urological Association, Quebec, Canada, June 27-30. Dr. Clyde L. Deming, 789 Howard Ave., New Haven, Conn., Secretary.
- Maine Medical Association, Bar Harbor, June 26-28. Dr. F. R. Carter, 22 Arsenal St., Portland, Secretary.
- Medical Library Association, Boston, June 28-30. Miss Janet Doe, 2 East 103d St., New York, Secretary.
- Minnesota State Medical Association, Duluth, June 29-July 1. Dr. E. A. Meyering, 11 West Summit Ave., St. Paul, Secretary.
- National Medical Association, Hampton, Va., Aug. 15-19. Dr. John T. Givens, 1198 Church St., Norfolk, Va., General Secretary.
- West Virginia State Medical Association, White Sulphur Springs, July 11-13. Mr. Joe W. Savage, Public Library Building, Charleston, Executive Secretary.
- Wyoming State Medical Society, Laramie, Aug. 7-9. Dr. M. C. Keith, 156 South Center St., Casper, Secretary.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1927 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Nutritional Value of Soybeans.—Horvath reviews the work done on the nutritive value of soybeans, enumerates the mineral constituents and their disease-protective properties and points out the relative low cost of soybean products. As an economic source of valuable and wholesome dietary elements the soybean probably has no peer. The presence of phosphatides in soybeans may have some special physiologic value because phospholipoids are constituents of all the body cells, the nervous tissue being particularly rich in phosphatides. In 1936 a protective factor against nutritional encephalomalacia of chicks was discovered in the nonsaponifiable fraction of certain edible oils, which are headed by soybean oil. It has been found by Miller and Robbins that, compared with most vegetables, soybeans have unusually large amounts of protein, fat, calcium, phosphorus and iron. Cooked immature soybeans proved to be a good source of vitamins A, B and G and a poor source of vitamin C. Besides bread and bakery products the other main outlets for soya flour are for the manufacture of crackers, pancake flour, cocoa-malt mixes, baby foods, chocolate, puddings, ice cream powders, macaroni products and sausages. The addition of soya flour renders these products more nutritious and palatable. The Food Research Division of the United States Department of Agriculture has stated that the most expensive food constituents are minerals, vitamins, proteins and fats. Soybean flour is rich in all these food constituents and yet

relatively cheap. The moderate cost of soybean flour makes it possible for people of small incomes to obtain the maximum of these essential nutritional constituents required by the body, which in the form of other foods might be beyond their reach.

Traumatic Lesions of Kidney.—From 1910 to 1933 Priestley and Pilcher encountered forty-five cases in which they made the diagnosis of rupture of the kidney by external trauma without penetration of the skin. Twenty-four of the patients were seen immediately or within one week following injury, eleven were first seen from one week to one month after the initial injury and the remaining ten patients were first seen from one month to several years or more after injury. The type of renal injury varied from slight subcapsular hemorrhage to complete pulpefaction of the kidney. In some cases the ureter or renal pedicle was completely avulsed. Hemorrhage, usually perirenal but occasionally intraperitoneal, was uniformly present and hematuria, either gross or microscopic, occurred in 95 per cent of the cases. Leakage of the urine around the kidney was common. Serious associated injuries elsewhere in the body were present in 13.3 per cent of cases. Healing may occur satisfactorily with medical treatment, or on the other hand urinary fistulas, hydronephrosis, pseudohydronephrosis, pyelonephritis or anatomic abnormalities of varying degrees may persist or develop. A history of trauma and hemorrhage and pain are cardinal points in the diagnosis, but they should also be substantiated by intravenous urography. In general, medical treatment immediately following the injury is preferred unless contraindicated. Subsequent operation may become necessary in some cases. The two deaths that occurred in the series were attributed to severe extrarenal trauma. Thirty-one patients were followed for a period of from four to twenty-six years subsequent to injury. Eleven patients who underwent nephrectomy are entirely free of symptoms; 73.7 per cent of those treated medically are entirely well and the remainder of the group have mild symptoms referable to the urinary tract.

Carbuncle.—Berman believes that a study of the microscopic anatomy of the skin on the back of the neck and on the face clearly explains the behavior of carbuncle and definitely establishes carbuncle of the face as a distinct entity. He studied 125 cases of severe carbuncle, eighty-three in men and forty-two in women. The majority occurred on the back of the neck in both men and women, but carbuncle occurred twice as commonly on the face of women, whereas it was more common on the scalp of men. The face is a dangerous place, for four of the nine deaths occurred in facial carbuncle. Most carbuncles occurred in patients without debilitating disease; this was more noticeable in women than in men. Obviously the "picking" of cutaneous infections is an important causative factor. Of all associated diseases, diabetes is most frequent.

Carbuncle of the face should be treated conservatively. The general mortality in facial carbuncle was 40 per cent. Carbuncle elsewhere on the body, associated with severe debilitating disease, must also be treated conservatively. Five of the nine deaths occurred in this group. The general mortality was 18 per cent. Carbuncle not on the face and not associated with severe disease should be treated by surgical intervention. This may be by excision or incision. The general mortality in this group was 1 per cent.

Insulin in Treatment of Acute Mania.—Grosh states that recently at the Ypsilanti State Hospital three cases have been observed of apparent diabetes mellitus occurring during the course of the manic phase of manic-depressive psychoses. Two of the cases referred to were studied not only during the periods of acute elation but also during lucid intervals of more normal activity. The study of the dextrose tolerance curves taken during these two periods demonstrates that, while in neither period are they consistently grossly abnormal, still there is a distinct prolongation of the blood sugar elevation during the elated period when compared to the curves obtained under normal conditions, which are suggestive of increased tolerance. This comparison suggested that there was some relative loss of tolerance during the attack for which insulin might be used in

a remedial role. In both of these cases it might possibly have been mere coincidence that the psychomotor activity was sharply cut down to the normal level after a few days of insulin therapy. None the less this type of therapy is suggested as a reasonable procedure in the acute elations in which the dextrose tolerance test reveals a relatively high type of curve when compared with the curve in normal activity.

Metrazol Convulsions in Schizophrenia.—Reese and his co-workers have been using metrazol since February 1937 in the treatment of forty-one cases of schizophrenia. Twenty patients have finished their treatment, while twenty-one others are still under treatment. A 10 per cent aqueous solution prepared from the solid drug, placed in 50 cc. rubber-capped vials and sterilized in an open sterilizer at 100 C. for thirty minutes, is employed. Of the twenty patients in whom metrazol treatment has been completed, four have been discharged in full remission, six are improved and ten have not been benefited. In observing these patients the authors have always kept in mind a comparison with insulin shock therapy. The two forms of therapy differ in many ways, despite their common goal of rendering the patient unconscious. With metrazol, if improvement is to occur, it generally appears quickly and proceeds in spurts; with insulin, improvement is slow and steady. Patients treated with insulin always exhibit their first lucid intervals in immediate relation to hypoglycemia, while those given metrazol do not show improvement until the first or second day after treatment. Stuporous catatonic patients do not respond well to insulin; however, they furnish the most suitable subjects for metrazol therapy. Patients in whom symptoms are of more than a year's duration show little or no improvement when treated with insulin; the status of such patients when they are given metrazol, however, may change considerably for the better, even though full recovery does not take place. A judicious combination of the two methods often seems to produce the best results.

Acute Diarrheas of Infancy.—Spradlin states that the prophylaxis of diarrhea resolves itself into the following measures: (1) prevention of the infant from becoming overheated, (2) pure, uncontaminated water, (3) intelligent conservative diet, (4) cautious, gradual introduction of new foods to the infant, (5) adequate refrigeration of the baby's food, (6) screening to prevent bacterial contamination by flies and (7) prevention of parenteral infection by avoiding colds and their prompt treatment when they occur. When an acute diarrhea does occur the child should be kept at absolute rest. If necessary, adequate rest should be secured by the use of sedatives. In early, relatively nontoxic cases, adequate fluids (maximum 15 cc. per pound of body weight) may be given by mouth. In the more severe cases the use of one or more transfusions, at intervals of from twenty-four to forty-eight hours, with cross-matched citrated blood is a life saving measure. When parenteral infections are found, the clearing up of these infections is essential to the cure of the diarrhea. Proper dietary management is secondary only to the maintenance of a satisfactory water balance and elimination of any parenteral infection. All patients should have a preliminary starvation period during which only fluids are given. This period may vary from eight to forty-eight hours or even longer, depending on the severity and duration of the case. At the end of this period, in all types but the putrefactive diarrheas, breast milk or the basic milk mixture, if of sound composition, may be resumed in markedly reduced quantities. As the diarrhea gets under control, the amount of the milk mixture may be increased gradually up to the normal requirement. In the proteolytic or ferment-

tative diarrheas the most rational treatment is the administration of an 8 per cent preparation of maltose and dextrin or corn syrup solution after the initial starvation period. This is followed after twenty-four hours by the use of thin cereal gruels for several days before dilute milk mixtures are resumed. The raw apple diet and methods based on it hold great promise of supplanting the older, more conventional methods of treating diarrhea. Saline or sodium bicarbonate colonic irrigations are of particular value when the fever is high or when there is much cramping. These may be followed by a thin starch solution as a retention enema. The following drugs merit consideration: purgatives, opium, bismuth, sedatives, stimulants, atropine, calcium gluconate, alkalis and specific drugs such as emetine, carbarsone, vioform or other antiamebic drugs.

Iontophoresis in Arthritis.—Bredall describes the treatment of arthritis by iontophoresis or ionization with the simple galvanic machine using acetyl-beta-methylcholine chloride. A 0.1 per cent or a 1:1,000 solution of the drug is introduced into the affected part from the positive electrode. Absorbent paper, sheet wadding, reinforced asbestos fabric paper or cotton filled bandage is saturated with the solution and wrapped round the part to be treated. On top of this a tin lead plate or strip is wrapped around the part and connected with the positive pole of the galvanic machine. A large regular moist pad electrode is placed under the back or over the abdomen and connected with the negative pole. The current is gradually increased to from 20 to 30 milliamperes and maintained for from twenty to thirty minutes. Then the current is slowly turned off, the electrodes are removed, and the parts are dried and wrapped. There may be a slight tingling sensation under the electrodes during the treatment but the strength of the current must always be within comfortable toleration of the patient. Iontophoresis is contraindicated in septic conditions and in bronchial and other types of asthma, and it must be used with caution in patients with a cardiac involvement. There was definite improvement in sixteen of twenty patients. Most of these patients have previously had a long trial of treatment with conventional methods without results. Many patients showed not only definite elimination of swelling and deformity but also improvement in strength and function.

Peritoneoscopy.—Benedict has made forty-eight examinations with the Ruddock peritoneoscope. There has been one fatality, in which pneumoperitoneum may well be considered as a contributory cause of death. The patient was in the terminal stages of multiple lung abscess, coronary disease and

possible echinococcic cyst of the liver. An error in judgment was made in subjecting him to the stress and strain of sedative drugs and peritoneoscopy. There have been no other complications except a subcutaneous emphysema in a few cases. No real errors in diagnosis have occurred. When patients are carefully selected, peritoneoscopy is attended with little risk. Those with serious pulmonary or cardiac disease are not good prospects. Abdominal adhesions may complicate the procedure, but by careful selection of the site of puncture difficulties have thus far been avoided. Peritoneoscopy may be indicated in any abdominal or pelvic condition in which the diagnosis is obscure or in which additional evidence is needed to confirm a diagnosis or to plan treatment. The procedure will frequently give information that will decide for or against laparotomy. Peritoneoscopy is useful in cancer, cirrhosis, tuberculous peritonitis, ascites, pelvic tumors, ectopic pregnancy and ovarian dysfunction. In one case an excellent view was obtained of a polycystic liver, in another case of supposed echinococcic cyst the liver was found to be normal, and in a third case in which there was a questionable palpable mass the peritoneal cavity was found to be normal. Serious cardiac or pulmonary disease may be a contraindication, for the peritoneal distention necessary for a satisfactory examination may somewhat embarrass the circulation and the diaphragmatic movements. Because of the danger of spreading infection, peritoneoscopy is contraindicated in inflammatory conditions. Peritoneoscopy will not replace exploratory laparotomy in all cases, but in certain cases it makes it possible to avoid major surgical operations. Peritoneoscopy requires local anesthesia, a stab incision and hospitalization of one day.

Chronic Arthritis and Undulant Fever.—Goldfain declares that the ambulatory and especially the chronic or subclinical cases of brucellosis in man should be of interest to the physician who would study carefully any case giving a history of rheumatic or arthritic symptoms. The symptoms of subclinical or chronic types of brucellosis (arthralgia, arthritis, headache, backache, malaise, weakness, neuritis or neuralgia, myositis, leukopenia, secondary anemia, spondylitis and persistent joint stiffness), in their entirety or in part, may well lead to a diagnosis of chronic rheumatic disease or chronic arthritis without brucel-

losis ever being suspected unless it is tested for properly. It has been quite definitely proved that the agglutination test may be negative in at least 5 per cent of the cases. Other diagnostic measures therefore must be used to determine its presence. These are the opsonocytaphagic test and the cutaneous test.

It's a Fact. Mary B. Miller, Pittsburgh.—p. 386.

Diseases from Meat and Dairy Products.—The diseases most frequently caused by contaminated foods are those of the intestinal group. These Koon lists as typhoid and paratyphoid fever, common diarrhea, bacillary dysentery, protozoal dysentery, cholera, helminthic infestations, undulant fever, food infection and food intoxication. Diseases other than those belonging to the intestinal group, such as septic sore throat, diphtheria, scarlet fever or tuberculosis, may be transmitted by food but, except in the case of septic sore throat, food constitutes merely an incidental and not the usual or principal agency of transmission. Flesh of animals suffering from diseases due to the Gärtner group of organisms, such as septicemia and diarrhea, or from puerperal fever or tuberculosis may serve to transmit pathogenic organisms to the consumer. Human infection with animal parasites, introduced through the medium of food, is of special interest because of the number of helminths and protozoa which pass all or part of their lives in the intestine. The only consequential source of trichinosis for man exists in hogs, although a variety of other animals may be infested. Infestation of swine can be controlled by a swine sanitation system. The campaign to educate the public against the use of any raw or partially cooked pork should be better organized and more intensive. There are several tapeworms (beef, swine and fish) which man shares with the lower animals. The most frequent form of food poisoning in man is caused by foods infested with members of the *Salmonella* (paratyphoid enteritidis) group or with other bacteria, especially the staphylococci. Of the foods involved, meat products are only slightly more frequently involved than nonflesh foods (68 per cent). Practicing physicians and those engaged in public health work can contribute largely to the epidemiologic control of disease by interesting themselves in and lending their efforts to securing local or state laws governing food inspection that are comparable to the federal meat inspection act. Such activities should be removed from the influence of local or state politics.

*Multiple Myeloma with Hyperglobulinemia. G. M. Decherd Jr. and L. Holland.—p. 129.

Multiple Myeloma with Hyperglobulinemia.—Decherd and Holland cite two cases of multiple myeloma which illustrate the highly variable clinical picture that this condition may present. The first patient showed an anemia, hypercalcemia and hyperglobulinemia, with a greatly accelerated sedimentation rate. Bence Jones protein was excreted in large amounts. There were probably extensive pulmonary metastases. The second patient was thought to have chronic arthritis on admission, but the pain in the chest and back was due to skeletal involvement by myeloma. There was nitrogen retention in the blood, without an elevation of blood pressure and a high serum calcium with normal phosphorus. An increase in blood proteins is uncommon and, when found, should lead one to suspect multiple myeloma. Myeloma should be considered in all atypical cases of renal disease showing nitrogen retention without hypertension. Renal involvement is found in approximately 70 per cent of cases, ranging from proteinuria alone to renal insufficiency. Bence Jones protein is found in approximately half of the cases of multiple myeloma, and its presence is strongly suggestive of this disease. However, other conditions may lead to the renal excretion of this protein, notably diseases involving the bone marrow, such as leukemia or metastatic carcinomatosis, or chronic accumulation of pus, as in empyema.

Personnel of Maternity Hospitals.—Bryce and Tewsley discuss an outbreak of three cases of puerperal fever and the measures adopted to deal with it and those designed to prevent future similar outbreaks. In addition to the recognized biochemical and serologic methods of classification of hemolytic streptococci, their sensitivity to four serologically distinct types of streptococcus bacteriophage was tested; it was not found to be in complete agreement with the results of the precipitin test. The variation of sensitivity to bacteriophage among strains falling into Lancefield's group A suggests, however, that this property might be used in epidemiologic studies. The incidence of throat carriers of group A streptococci among the contacts of the three patients with puerperal fever was found to be 22 per cent. On two subsequent occasions, when there had not been recent known contact with streptococcal infections, the incidence of group A streptococci among similar groups of medical practitioners and nurses was respectively 3 and 6.7 per cent. In persons with healthy respiratory tracts the presence of hemolytic streptococci in throat swabs appeared to be closely associated with recent contact with streptococcal illness. In the personnel with clinically detectable abnormality of the nasopharynx there was a greater tendency to harbor hemolytic streptococci irrespective of recent contact. Exclusion from maternity units of persons with such abnormality, by means of preliminary medical examination, would be a possible way of reducing the risk of infection of patients and the disorganization attendant on their withdrawal during a period of obstetric work.

*Urea Clearance Test (Coefficient of Van Slyke) in Study of Renal Function. Pasteur Vallery-Radot, P. Delafontaine and J.-F. Forge.—p. 697.

Shortening of the Mean Delay Between the Age of Primary Tuberculous Infection and the Age of Pulmonary Tuberculosis as a Disease: Practical Consequences. E. Bernard and J. Weil.—p. 698.

Urea Clearance Test (Van Slyke) and Renal Function.

—Pasteur Vallery-Radot and his collaborators, after calling attention to Ambard's laws on the concentration of urea in the urine and in the blood, review the studies of American authors on the excretion of the urea in the volume of urine, citing Van Slyke's formulas for the maximal clearance and for the standard clearance of urea. The formula for the maximal clearance is applied if the volume of urinary secretion is equal or superior to 2 cc. per minute; that for the standard clearance is employed when the urinary secretion is below 2 cc. per minute. The authors made comparative studies with Ambard's constant and with Van Slyke's formula for urea clearance on sixty-one patients. In forty-six (75 per cent) the tests of Ambard and Van Slyke produced comparable results. Eleven of these forty-six subjects were free from renal disturbances according to the tests, whereas the thirty-five others had manifest renal insufficiency. In fifteen subjects (25 per cent) the tests of Ambard and of Van Slyke gave discordant results. In one case the test of Van Slyke was abnormal, while the constant of Ambard and the other functional tests gave normal results. In fourteen other cases, Van Slyke's test was normal when Ambard's disclosed increased values; in ten of these subjects the other renal tests gave normal results. The authors say that it cannot be concluded from this that one test is more sensitive than the other, for the two tests estimate the urea secretion on a different basis. They think that the urea clearance test of Van Slyke has a place among the other renal tests. It is simple and gives evidence of the renal "flexibility." This functional flexibility of the normal kidney is opposed to the functional rigidity of the diseased kidney. A number of investigators have accepted this idea as fundamental.

*Study of Exchange of Vitamin C of Mother and Nursing Infant. W. Neuweiler and J. Hubscher.—p. 734.

Vitamin C in Mother and Nursing.—Neuweiler and Hubscher investigate whether pregnancy and lactation produce changes in the metabolism of ascorbic acid. First they give their attention to the problem as to how the fetal organism obtains the ascorbic acid necessary for its growth. They consider it demonstrated that the fetus receives the vitamin C from the maternal organism, for a synthesis of ascorbic acid in the fetal organism is highly improbable. The great ascorbic acid content of the placenta is a reserve placed by the maternal organism at the disposal of the fetus. Studies revealed that the blood of pregnant women has a much lower vitamin C content than has the blood of nonpregnant women. Tests on the urines of pregnant and lactating women disclosed that the vitamin C deficit is greatest in the nursing mothers. The authors also investigated the vitamin C content of the milk. They studied human milk, cow's milk and goat's milk, these being the only types of milk customarily used for the feeding of infants. They found that human milk contains from five to six times more vitamin C than does cow's or goat's milk. The animal species which are capable of effecting a synthesis of vitamin C have a milk that is poor in vitamin C. The quantity of vitamin C contained in the milk of women suffices for the normal needs of the infant, whereas the milk of cows and goats is insufficient in this respect. Comparative studies on the urinary elimination of vitamin C in nurslings revealed that infants receiving large amounts of vitamin C eliminate much more than those receiving little. It was found also that the quantity required by the nursling is relatively large; it amounts to approximately 6 mg. per kilogram daily. On the basis of their observations, the authors conclude that artificially fed infants must be given added quantities of vitamin C in the form of lemon juice or of a synthetic

vitamin C product. Regarding the nursing mothers, they say that a rational diet furnishes nearly all the vitamin C necessary. One or two oranges a day suffice and more than cover the needs of the nursing mother.

*Serous Meningitis. M. Molhant.—p. 329.

New Anatomoclinical Observation of Sclerosis with Acute Plaques. Riser and Geraud.—p. 348.

Serous Meningitis.—Molhant says that the term serous meningitis was employed first by Quinke to characterize the excessive production of cerebrospinal fluid with accumulation in the cerebrospinal spaces. Before taking up the different forms of serous meningitis, the author discusses the biologic physiology of the cerebrospinal fluid. He emphasizes the importance of the biologic equilibrium of the cerebrospinal fluid on the stimulation of the hypothalamic sympathetic centers and the role of the cerebrospinal fluid in the regulatory mechanisms of the humors. He shows that the clinical aspects of localized serous meningitis, at least in its simple forms, are the manifestation of an organofunctional pathogenic complex. The meningeal cyst is a sequel of a subacute inflammation of the brain and meninges. The treatment of choice is the intradermal tuberculin desensitization. Discussing the generalized cerebral serous meningitis, he takes up first the purely toxic forms, which are caused essentially by the noxious action of certain endogenous toxic substances. Hypertonic solutions of dextrose in massive doses, repeated for several days, have a remarkable curative action in the acute cases. The second type of generalized meningitis discussed by the author is the form that is due to toxic sensitization either by a medicinal or by an infectious factor. The reported histories indicate intoxication with phenobarbital, alcohol, gold salts and so on, the presence of chronic evolutive tuberculous processes or the combination of these medicinal and infectious factors. In these cases the administration of hypertonic solutions of dextrose constitutes the treatment of choice during the acute periods. In the chronic forms repeated lumbar punctures, decompressive craniectomy and other intracerebral interventions have been recommended. Roentgen treatment has also been recommended because under its influence the production of cerebrospinal fluid is decreased. The author utilized with good success intradermal tuberculin desensitization. This treatment is simple, inoffensive and at the disposal of the general practitioner. By its para-allergic action it dynamizes and regulates the apparatus of disturbed biologic regulation of the dyscrasic organism. It has a desensitizing action. By its specific allergic action it contributes also to the cure of the tuberculous lesions.

Abdominoperineal Amputation of Rectum. P. Decker.—p. 463.

Billroth I in Secondary Gastric Operations.—Clairmont points out that it was von Haberer who, by changing and improving the technic of Billroth's first method, made it suitable not only for the primary resection on account of gastric or duodenal ulcer but also for the complicated after-operations on account of disturbances after gastro-enterostomy. The author describes the clinical histories of three patients and demonstrates that the resection according to the first method of Billroth is the best intervention in counteracting the unfavorable results of gastro-enterostomy and in reestablishing physiologic conditions. Clairmont admits that the surgeon who uses Billroth's first method rarely or not at all for gastric resection will hardly find the courage to use this method in the more complicated cases of second or third interventions. However, the three reported cases, as well as other reports in the literature, demonstrate that especially in these complicated cases the first method of Billroth produces excellent results, which are not obtainable with other methods.

Etiology of Articular Osteochondroma.—Carnevali made microscopic studies of osteochondromatous nodules which had been removed surgically from the knee of a patient. The patient, aged 40, had had gonorrheal purulent arthritis, which was treated by arthrotomy. Some years later roentgen examination of the knee joint showed intra-articular calcification. On operation a great number of nodules, both loose and adherent to the synovial membrane, were found and removed. On microscopic study the loose nodules were found to be in the final stage of a proliferating process. The cartilage was preserved by osmotic nutrition. The osteogenic process was still in progress in the center of the pedunculated nodules, while the cartilaginous layer was well preserved. The author reviews the literature and discusses the infectious, traumatic and embryologic theories on the pathogenesis of intra-articular osteochondroma. He believes that the disease is due to the presence of intra-articular infection or of acute or chronic inflammation which induces alterations of the physicochemical condition of the synovial membrane with consequent primary hyperplasia and secondary metaplasia. The metaplastic synovial villi develop into the chondromatous nodules, in the center of which processes of calcification and ossification take place as long as the nodules have vascular connections with the synovial membrane (sessile and pedunculated nodules). When the nodules become detached from the synovial membranes, the phenomena of calcification and ossification of the center of the nodules stop. The bone portion of the nodules appears as atrophic old bone, whereas the cartilaginous layer of the nodule shows a living aspect since it continues to receive nutrition by osmosis.

- Treatment of Ancylostomiasis. M. Mazzitelli.—p. 97.
- *Secretory Functions of Stomach in Course of Atropa Belladonna Treatment. E. Nicolini.—p. 99.

Stomach During Treatment with Belladonna.—Nicolini determined the secretion of hydrochloric acid in the stomach in two groups of patients who had postencephalitic parkinsonism and who were being treated with atropa belladonna. In one group of fifteen patients the treatment had been given for a short time in small doses. In the other group of sixteen patients it had been given for a long time in large doses. Determinations of the hydrochloric acid secretion were made by examination of the gastric secretion, which was withdrawn at intervals of fifteen minutes during the first hour after administration of an Ewald meal test. The author found that in the majority of cases the hydrochloric acid secretion is diminished before the treatment is given, in the course of which it diminishes still more. In a few instances achlorhydria appears. There is no fixed therapeutic dose by which lasting inhibition of the hydrochloric acid secretion may be induced, as the effect depends on the individual tolerance and ability of the patient to accustom himself to the drug. Small doses of belladonna may inhibit the hydrochloric acid secretion in some cases, whereas large doses are necessary to inhibit it in others. In some cases in which the secretion is normal before the treatment, it does not change in the course of the treatment, even though paralysis from the vagus develops in other parts outside the gastric territory. In some patients showing hyperchlorhydria before the treatment, the hydrochloric acid secretion becomes normal in the course of the treatment. According to the author the results of his observations show that the secretory functions of the stomach do not depend

entirely on vagal innervation. The latter conception should be kept in mind when the production of lasting changes of the gastric secretion, by means of vagal inhibition, is indicated in the treatment of certain diseases, such as in the treatment of hypersecretory neurosis by atropine.

- *Pleural Incontinence. A. Cordeiro Junior and F. Benedetti.—p. 913.

Pleural Incontinence.—Cordeiro Junior and Benedetti report two cases of incontinence of the pleura to pneumothoracic insufflations in patients with pulmonary tuberculosis. The insufflations of 200, 500 and 800 cc. of gas, in three different attempts, failed in each case to induce pneumothorax. There was no technical error. Roentgenoscopy showed no gas collection in the pleura. The roentgenograms showed no collapse of the lungs. According to the author, the cause of the refractivity of the pleura for pneumothorax is the presence of a pleuro-bronchial fistula without any spontaneous pneumothorax. The gas enters by the pleura and is immediately eliminated through the bronchi. Two factors are of importance: the presence of adhesions around the fistula, which prevent the formation of spontaneous pneumothorax (anatomic factor), and the expansion of the lung from stimulation of the vagus nerve (physiologic factor).

Ophthalmologic Studies on Hereditary Nature of Aging.—Vogt points out that the various signs of senility in uniovular twins have such a degree of similarity or even identity that the formerly accepted opinions of the aging process as a result of environmental factors must be abandoned. The study of senile uniovular twins demonstrates that the signs of the process of aging are inherent in the germ plasm (uniovularity presupposes identical germ plasm of the twins) and that they appear with absolute uniformity at a certain age and in a predestined form. The author's conclusions regarding the hereditary character of the process of aging are based on observations on thirty-four sets of uniovular twins between the ages of 55 and 81. In this report he observes the symptoms of aging on certain parts of the eyes of uniovular twins. Discussing the senile changes on the conjunctiva, he shows that in aged uniovular twins pinguecula as well as spontaneous pterygium appear at about the same time and in the same localization, and he concludes that hereditary factors must play a part in the development of those defects. He further describes and illustrates senile changes on the cornea of sets of uniovular twins. He shows that unilateral, excessive atypical, premature, slight or absent arcus senilis must be hereditary, having observed identical characteristics not only in successive generations but also in sets of senile uniovular twins. Then he demonstrates the hereditary character of Krukenberg's pigment spindle and of the cornea guttata senilis. Following a discussion of the senile degeneration of the pigmented edge of the pupil and the hereditary predestination of this symptom, the author takes up the study of senile cataract in uniovular twins. That the type of senile cataract is hereditary he demonstrates on different sets of senile uniovular twins. Finally he shows that the senile changes in the vitreous body and in the fundus oculi of twins indicate the hereditary nature of these changes also.

Adsorption of Virus by Aluminum Hydroxide.—Schmidt describes the development of an aluminum hydroxide preparation which has a strong adsorbent action for toxin and virus, particularly the virus of foot and mouth disease. The adsorption was studied on the virus in virulent lymph, in the extract from the aphthae, in the virulent serum and on the cultured virus. Virus adsorbents that are produced according to the author's technic are infectious for guinea pigs in case of intramuscular, intraperitoneal or intracutaneous injection. However, if introduced into the subcutaneous tissues the adsorbents are comparatively harmless but develop a rather potent and prolonged specific immunity against foot and mouth disease. It is possible to produce virus adsorbents that contain two or three types of viruses. A single injection of a preparation of this type may produce, under favorable conditions, a potent and permanent immunity against two or three types of viruses. Storage reduces the pathogenic characteristics of the virus adsorbents produced with aluminum hydroxide, but they retain, at least partly, the immunizing capacity. In case of comparatively high temperature, about 37 C., the rapid disappearance of the infectiousness is accompanied by a considerable reduction of the antigenic property. Freezing and drying destroy the pathogenic as well as the antigenic properties of the adsorbents. In the animal organism (subcutaneous tissue) the virus adsorbents undergo rapid changes. The pathogenic capacity disappears rapidly. However, the immunizing capacity is partly preserved and may still be demonstrated in adsorbents that have been in the animal organism for two weeks, in spite of the fact that the organism is already immune.

Ustilaginism in Children.—Mayerhofer and Dragišić describe observations on fifteen children with ustilaginism, but they also induced ustilaginism in mice and compared the symptoms in the animals with those in the children. They found that young children and nurslings are especially susceptible to ustilaginism and the animal experiments disclosed that young mice too are more readily poisoned with *Ustilago maydis* (smut of maize) than are older mice. Discussing the symptomatology of ustilaginism, the authors say that the disorder frequently begins with gastrointestinal disturbances in the form of diarrhea. Acropathic cutaneous manifestations, particularly severe burning, itching or formication on the palmar and plantar surfaces, is another important symptom. Hyperemia of the extremities often alternates with acrocyanosis. The alternating changes between hyperemia, cyanosis and pallor are noticeable also on the tip of the nose. It is suggested that this variable symptom is the result of an intoxication of the small cutaneous vessels and that the cutaneous edema of the arms and legs, which occurs in severe cases, is likewise a result of this impairment of the cutaneous vessels. If the acrocyanosis persists for longer periods, acrogangrene may develop. The authors observed this

in three of the fifteen cases. On the mucous membranes, gums, lips, conjunctiva and so on, ustilaginism often elicits reddishness, swelling and itching. The tachycardia with hypertension which develops in the severe cases is one of the most persisting symptoms. Nervous disturbances are also likely to develop in cases of ustilaginism; there may be latent or manifest spasmophilia, muscular spasms and pains, nervous irritability, restlessness and delirium. Then there may be some nonessential secondary symptoms such as interdigital rhagades, pigmentations on the tips of the fingers and toes, sensitivity to sunlight and so on. Regarding the differential diagnosis, the authors say that if the anamnesis of a child with acropathy discloses that it has been fed with maize flour in which spores of *Ustilago maydis* can be seen the disorder may be diagnosed as ustilaginism rather than as true infantile acrodynia, ergotism or pellagra. Moreover, ustilaginism, even severe cases, usually responds to dietetic treatment within a few weeks, whereas acrodynia and pellagra last much longer.

Diagnosis of Addison's Disease from Blood.—In studies on changes in the composition of the blood of nephrectomized rabbits Riml found a substance which, when transferred to normal guinea pigs, produces signs of fatigue as well as changes in the adrenals that must be regarded as signs of an increased functional load, for they fail to develop when adrenal cortex extract is administered. The author decided to investigate whether changes similar to those in nephrectomized animals could be observed in patients with adrenal insufficiency. A dialysate of the serum of patients with Addison's disease was administered by intraperitoneal injections to guinea pigs. Control animals of the same size were given injections of a serum dialysate of persons without adrenal defects. Later the animals were killed and their adrenals subjected to microscopic examination. The author made the tests on three patients with Addison's disease. He found that the serum dialysate of these patients contains a substance which, when transferred to guinea pigs, produces in the adrenals of these animals changes which are interpreted as signs of an increased functional load. The severity of the changes in the adrenals of the test animals goes almost parallel with the severity of the Addison's disease in the patient. After the treatment with adrenal cortex extract the serum of the patient no longer contains the substance that causes changes in the adrenals of guinea pigs, but when the treatment with adrenal cortex extract is discontinued the substance reappears.

Pernicious Anemia in Chronic Polyarthrit.—Schneiderbauer describes three cases of primary chronic deforming polyarthrit in which, after this disorder had existed for several years, there developed a genuine pernicious anemia with all objective clinical and hematologic signs. In one of the cases the pernicious anemia developed immediately after an acute exacerbation of the articular disturbance. A causal connection between these disorders, which seems probable in view of the clinical symptomatology, seems even more likely on the basis of Castle's observations. It is suggested that the chronic polyarthrit, as an infectious process, produced by way of the hematogenic route a chronic gastritis with atrophy of the gastric mucosa and subsequent impairment of the secretory functions, so that in addition to the gastric achylia there was a cessation of the production of the intrinsic factor of Castle. This disturbance resulted in the development of a secondary pernicious anemia. The author's observations indicate that the infectious toxic factor is one of the causes that may lead to a cessation of the secretion of Castle's principle. He thinks that Naegeli's opinion that there are only three eliciting factors (syphilis, pregnancy and bothrioccephalus latus) for secondary pernicious anemia is no longer tenable.

Occupational Cancer in Asbestos Workers. M. Nordmann.—p. 288.

Multiple Appearance of Tumors.—Holmqvist and Nelson state that a number of investigators have given their attention to the exact definition of the term primary multiplicity but have failed to agree. However, all of them emphasize how important and difficult it is to differentiate metastases from the primary multiple tumors. The authors aim to show under what conditions multiplicity occurs and what factors influence multiplicity and to compare the results obtained on their own material with those obtained by other authors. For this reason their method of classification was to a certain extent influenced by that of others. Like Puhf, the authors have classified hypertrophy of the prostate with the tumors, although they are aware that the blastomatous nature of this hypertrophy may be questioned. The material on which the authors base their conclusions comprises 4,000 unselected cases that came to necropsy at the hospital of St. Erik in Stockholm. Tumors were discovered in 55.8 per cent of the cases. Primary multiplicity of tumors was discovered in 22.5 per cent of the cases. The multiplicity seems to be influenced by age and sex. A tendency to multiple appearance seems to increase with the years; women have a greater tendency for multiplicity than have the men of the same age. Multiplicity is more frequent in benign than in malignant tumors. The following combinations are especially frequent: uterine myomas and uterine polyps, benign tumors of the uterus and benign tumor of the endocrine organs, particularly of the thyroid, and finally benign tumors in the different portions of the digestive tract. A tendency for the formation of benign tumors may involve the entire body, a system of organs, organs or parts of organs. Factors prevailing in case of primary multiplicity of tumors justify the assumption of a probably genetically conditioned local diathesis. Moreover, the authors suggest the possible existence of a similar generalized tumor diathesis.

*The Lungs as Most Frequent Seat of Primary Foci of Rheumatic Infection. J. Havas.—p. 440.
Vitamin B₂ (Riboflavin) Treatment. S. Kalter.—p. 446.

Lungs as Foci of Rheumatic Infection.—On the basis of four case records, Havas says that the possibility of primary pulmonary foci of rheumatic infection is established. The high statistical incidence of chronic bronchitis among rheumatic patients in whom no other demonstrable foci, such as teeth or tonsils, exist indicates that the majority of rheumatic disorders are of pulmonary origin. The rheumatic foci are based on pulmonary lesions of the ulcerous-cavernous type which have healed by scarring. Rheumatic alterations and lesions in the joints and their adnexa depend on local allergic influences, which are released in some instances by the bacilli of tuberculosis but most frequently by the common bacteria of the mixed infection of ulcerous pulmonary processes.

Roentgen Therapy of Malignant Granuloma.—Spritzer has treated fifty-six patients with malignant granuloma by roentgen therapy. He divided them into two groups. In

group 1 twenty-seven patients had been treated between the years 1926 and 1932. These patients had been given low voltage roentgen therapy averaging from 200 to 300 skin doses in the region of the external glands and from 500 to 600 skin doses in the region of the internal glands. This series of roentgen therapy was repeated after several months had elapsed, according to the physical condition of the patient. In group 2 there were twenty-nine patients to whom roentgen therapy had been applied between the years 1932 and 1936. These patients had been given large fractional doses, externally from 800 to 1,200 roentgens and internally as much as 5,000 roentgens. In cases of relapse, roentgen therapy was repeated. It has never been applied on healthy glands. In conclusion he says that roentgen therapy of malignant granuloma cannot be employed schematically but must be used individually. It should be applied only to diseased glands, the rest of the lymphatic system being spared as much as possible. It should be administered only in case of relapse and not as a preventive. In the early stages of disease weak doses should be prolonged, if possible, in order to lengthen the life of the patient. In later stages it is necessary to give more intensive treatment. Roentgen therapy should be applied also to the bones in each case.

*Genesis of Cerebral Gliomas. V. G. Lazarev and A. D. Dinaburg.—p. 1369.

Genesis of Brain Gliomas.—Lazarev and Dinaburg studied eighty instances of glioma and found that 25 per cent of them exhibited embryonic origin. Considered from an embryologic point of view, the tumors were divided into four groups: (1) those of dystrophic origin, (2) those exhibiting embryonal foci enabling one to follow the course of development of the growth, (3) those associated with anomalies and developmental malformations and (4) those in which glioma was associated with gliomatosis. The first group was represented by seven cases, of which six were in children, with a localization in the region of the vermis of the cerebellum, tumors of the median line designated cytologically as medulloblastomas. The development of these tumors in children, their median localization corresponding to the fissure in the closure of the neural tube—regions giving rise to a number of anomalies and developmental malformations—speaks in favor of embryonal origin. In three of these cases the authors found a hyperplasia of the reticular tissue and they felt justified in designating this variety of tumor a reticuloglioma. A second group, consisting of four astrocytomas, exhibited a conglomeration of cells identical with "growth centers" described by Obernsdorfer in ganglioneuromas and neurinomas. These growth centers were localized principally in the neighborhood of blood vessels. In some instances they consisted exclusively of elements characteristic of an early embryonal stage (medulloblasts); in others there were found, in addition, more mature types of cells representing a transition to astrocytes. As a rule, mature astrocytes are found outside the growth centers. The transitional elements may be found scattered throughout the tumor tissue. In one case of astrocytoma there was observed along with the growth centers an additional tumor consisting of embryonal elements. The presence of a second mature astrocytoma in the opposite hemisphere of the brain enables one to regard growth centers as a manifestation of multicentric growth of the tumor. The third group was represented by three cases in which glioma was associated with heterotopias, irregular formation of the radiations of the cerebellum, development of accessory radiations, and so on. The fourth group was represented by seven cases in which, in addition to the circumscribed growth of the type of astrocytoma, there was observed in the opposite hemisphere gliomatous proliferation representing a developmental anomaly of glial tissue capable of transformation into a genuine glioma under conditions that are still not understood.

Gonorrhea in Women.—Simons and Eindhoven report their experiences with an acridine derivative in the treatment of eighteen women with gonorrhea. The preparation used by the authors was flavidine, an acridine preparation which contains arsenic in an organic combination and which, while not irritating like acridine hydrochloride, nevertheless has a good gonococcidal action. The preparation was first used for the treatment of gonorrhea in 1932. Favorable reports about the preparation induced the authors to employ it in acute cases of gonorrhea, in preference to the new sulfanilamide preparation, which is better suited for the chronic cases. Before treatment is instituted, cultures are made from material obtained from the urethra, cervix and rectum. In the treatment of the cervix uteri, the organ is exposed with the aid of a speculum, the secretion is wiped away and then the flavidine is introduced by means of a syringe. At first 1 cc. is administered, then 2 cc. and then 3 cc. If some of the fluid flows back, it is wiped away to avoid erosions. For greater safety a tampon is introduced into the vagina; this can be removed by the patient on the following morning. The treatments are given daily for eight days. After each series a control test is made. From one to six series are required for the treatment of cervical gonorrhea, but the average is about three series of eight days each. In approximately half of the women treated, the cervix was cured after eight days. In rectal gonorrhea, in which flavidine was equally effective, 5 cc. was instilled and from one to four series of treatments were required for cure. The urethra was not treated with flavidine but rather with the usual silver preparations. The silver therapy required one or two months longer than the treatment with flavidine, but the cervix was never reinfectd from the urethra. Reviewing the results of the flavidine treatment, the authors say that all eighteen women were cured. Control examinations extending over periods of from three to twelve months proved that there was only one relapse, which actually may have been a reinfection. On the basis of these observations the authors think that flavidine is the remedy of choice in the local treatment of gonorrhea in women.

Ureteronephrectomy in Renal Tuberculosis.—Van Gelderen reports that in a series of thirty-seven patients with renal tuberculosis primary ureteronephrectomy was carried out systematically. This did not augment the risk for the patient, in the form either of an increased operative mortality or of a higher mortality shortly after operation. The ureteral wound nearly always healed primarily and permanently; disturbance in the healing of the renal wound did not occur less frequently than in simple nephrectomy, so that the ureter cannot be looked on as the cause of this disturbance, except in rare cases of long standing. Ureteral empyema, cold abscess and acute abdominal pains are prevented. Even in the unfavorable class of patients the lasting results were found to be favorable; only three patients died, and in all the mortality was of the remote type. Thus nothing was experienced of the disadvantages ascribed to the method by some; the expected advantages to some extent were not found (wound healing), but if present they could clearly or most probably be ascribed to the ureteronephrectomy (lasting results, rapid healing of the bladder). The operation deserves to be advocated.

Mechanism of Decrease of Acidity in Gastric Contents.—Boldyreff and Martin maintain that the chief factor in limiting the acidity of the gastric contents is food, particularly protein, but they do not discuss this phase of the problem. They emphasize that there is no such thing as hyperacidity, because gastric juice is always secreted with a definite degree of acidity of about 0.5 per cent of hydrochloric acid. They think that it would be better to abandon the term hyperacidity, substituting for it a more fitting term such as hypersecretion. Discussing the disagreement between clinicians and physiologists about the acidity of gastric juice, they say that for about 100 years clinicians considered it to be about 0.15 per cent, whereas the physiologists since the time of Heidenhain have maintained that it was about 0.5 per cent. Only in the twentieth century did the investigation of so-called duodenal regurgitation furnish an explanation. The authors describe the phenomenon of regurgitation of the duodenal contents into the stomach containing acid. They describe and discuss experiments by Boldyreff, Lewis and Slagle. The tests that were made on man and dogs may be classed in three groups: The first group demonstrates that in the presence of acids in the stomach there always is a decrease in the acidity (neutralization of acidity). Analyses of the chloride content, after hydrochloric acid has been administered, indicate that the main part is played not by dilution of the liquid but by binding of the acid. The second group of experiments demonstrates that neutralization is effected from the duodenum, because, if the stomach or a portion of it is isolated, the neutralization is never normal. The presence of bile and intestinal mucus during the process of neutralization explains the source of the liquid which binds the acid. The third group of experiments shows that removal of duodenal fluids almost entirely excludes the process of neutralization. The authors reach the conclusion that the main factor in the neutralization of acidity in the stomach is the alkaline pancreatic juice which is regurgitated from the duodenum while there is still powerful acid present in the stomach. The gastric mucus also effects a certain binding of the acid introduced into the stomach. Dilution plays an insignificant part in the reduction of the acidity of the gastric contents. Normally this is achieved by the pancreatic juice which comes from the intestine. In pathologic cases, with insufficient action of the pancreatic gland, dilution is achieved by saliva, bile and intestinal juice. Participation of the pyloric juice is also quite probable.

High Protein Diet in Nephritis.—It is pointed out by Næraa that, owing to the complete failure of drug therapy in hemorrhagic nephritis, the diet has always been an important problem in the treatment of this disease. A milk diet was long considered preferable. In recent years, however, it has been replaced by a diet rich in carbohydrate but poor in protein. Ever since 1879, when Aufrecht set up his strict diet, protein has practically been banned from the diet of nephritic patients. In the last six or seven years, various authors (encouraged in particular by Epstein's studies on the pathology of nephrosis) have insisted more and more convincingly that protein ought to be introduced in the treatment of nephritis. In 1925 Addis gave a method for the determination of the numbers of erythrocytes, leukocytes, epithelial cells and casts in the urine. In 1933 the author adopted this method in order to study the possible noxious effect of a high protein diet on patients with acute nephritis. The plan was to give patients with acute or latent hemorrhagic nephritis alternately low and high protein diets. As soon as the patients entered the hospital they were put on a diet consisting of 250 Gm. of cream, 250 Gm. of milk, 250 Gm. of fruit, 200 Gm. of bread, 500 Gm. of green vegetables, 100 Gm. of potatoes, 100 Gm. of butter and 250 Gm. of oatmeal porridge

with sugar. Only if the patients on admission were seriously ill, with oliguria, nausea and vomiting, were they given another diet, i. e., a limited supply of water and almost an absolute fasting diet. As soon as they had any desire for food they were given the aforementioned diet. This diet represents a daily intake of about 2,750 calories with a protein content of about 40 Gm. Each patient was kept on this diet for a variable length of time, while he was under observation and the diagnosis was established. The feature that decided when the patient was to be given the high protein diet was most often behavior of the hematuria. As a rule the author waited till the hematuria had become fairly constant as estimated by daily counts. The high protein diet consisted of the same food articles as previously listed, except that the 250 Gm. of oatmeal porridge was replaced by 250 Gm. of lean beef, usually in the form of a steak. Given in this way, the diet represents more than 3,000 calories and contains about 125 Gm. of protein. The patients were given these two diets alternately, through periods varying from eight to nineteen days. Quantitative examination of the urinary sediment in ten patients having various forms of hemorrhagic nephritis who were treated in this manner showed nothing to suggest that a high protein diet is injurious to the kidneys of such patients.

Urinary Sediment After Six Day Bicycle Race.—Næraa says that, since Addis in 1925 presented his method for quantitative urinary sediment determination and demonstrated the occurrence of hyaline casts and red blood cells in the urine of normal persons, the interest in the physiologic variations in the amount of these elements has been aroused anew. The fundamental question now arises whether physical exertion produces an increase in the number of erythrocytes and casts normally present in the urine and whether other kinds of casts besides the hyaline may appear under the same conditions. In order to elucidate this question the author made sediment counts on thirty-four specimens of urine from twelve men who took part in a six day bicycle race in Copenhagen in 1934. He used the method of Addis. He says that his studies on the urinary sediment of these men disclosed no signs of renal lesions.

Types of Pneumococci in Acute Pneumonia.—Gard and his associates point out that the type differentiation of the pneumococci has opened up fresh avenues of approach for the study of the epidemiology and therapy of the pneumococcal infections. The satisfactory experiences gained abroad with specific serum therapy have led to its being tried in Sweden. The aim of the researches reported in this paper has been to ascertain the importance of various types of pneumococci as a cause of pneumonia. The authors reach the conclusion that the sharp line of distinction between croupous lobar pneumonia and catarrhal bronchopneumonia cannot be maintained. Acute pneumonia presents varying pathologico-anatomic appearances ranging from the fibrinous, lobar form, passing gradually into catarrhal bronchopneumonia and showing intermediary and mixed forms with variations in regard to the abundance of fibrin and the lobar dispersion. The pathologico-anatomic diagnosis made on the basis of clinical and roentgenologic observations is of course of value in determining the prognosis, but its importance in that respect is enhanced if it is supplemented by a bacteriologic investigation, which moreover is absolutely essential as a preliminary to a specific therapy. The authors have not been able to confirm Gundel's theory that the pathologico-anatomic aspect of pneumonia is determined entirely by the serologic type of the pneumococci. Other factors play at least as important a part in this respect. If, then, it is hardly justifiable from that point of view to ascribe any special position to types 1 and 2, never-

theless it cannot be denied that type 1 predominates in the frequency statistics in spite of the fact that several of the other types have proved to be capable of causing pneumonia with as high a rate of mortality or one even higher. Gundel's assumption that dissimilarities in the mechanism of infection (exogenous-autogenous infection) is the decisive factor in this respect can hardly be accepted as a satisfactory solution of the problem. From the investigations the authors have carried out it appears that approximately half of the lobar forms of pneumonia are caused by pneumococcus type 1, so that the production of type 1 serum for therapeutic use must be regarded as one of the most important means of reducing mortality from pneumonia. The next step would be to make serum against types 2 and 7. The experience gained abroad as to the effect of serum against these three types of pneumococci has been extremely favorable.

100: 177-224 (March 31) 1938

*Meningeal Hemorrhages, Originating from Rupture of Aneurysm in Basal Arteries of Brain. R. Luft.—p. 177.

*Gas Phlegmon in Lund Surgical Clinic from 1920 to 1936: Cases. F. Koch.—p. 194.

Meningeal Hemorrhages.—Luft reported twenty-five cases of meningeal hemorrhages due to rupture of an aneurysm in the basal arteries of the brain. The most frequent localization was the middle cerebral and the anterior communicating arteries. The aneurysms varied in size but were usually as large as a pea. He says that, on rupture of the aneurysm, intrameningeal hemorrhage along the base of the brain generally occurs. In many cases the hemorrhage in the meninges is complicated by disturbances in the brain parenchyma near the aneurysm. Lumbar puncture, done in eleven cases, showed microscopic blood in two and macroscopic mixture with blood in nine. The pressure of the spinal fluid was abnormally high. The combination of sudden cerebral symptoms and sudden stiffness of the neck supports the diagnosis of ruptured aneurysm. The smaller hemorrhages cause dulness and apathy; the more massive bleedings may result in death without the patient's return to consciousness (nine cases). Irritation of the brain cortex causes spasms, a common symptom. If the hemorrhage damages the brain substance near the aneurysm, hemiplegia and hemiparesis result (nine cases). In eleven cases there were disturbances in the pupillary reflex; in six, anisocoria; in five, paresis of the muscles of the eye; paralysis of the facialis nerve occurred in four cases, all with aneurysm in the anterior cerebral artery. The symptoms may suddenly disappear, to be followed by a second hemorrhage, often in a period free from symptoms. The blood pressure is frequently no higher than is normal for the patient's age. Atherosclerosis appeared in only two of the patients under the age of 60, and was no more marked in the patients over 60 than was to be expected at the age. The theory that atherosclerosis is the primary cause of the aneurysm or the immediate factor in cases of congenital defect in the wall of the blood vessel is therefore not accepted. There was neither history nor sign of syphilis in any case. Great importance is attached to congenital defects. While the author has found no record of any case in which there was recovery, in two reported cases the first hemorrhage occurred seventeen and twenty-one years, respectively, before the second, fatal hemorrhage (Fearn-side).

Gas Phlegmon in Lund Surgical Clinic.—Six of Koch's twenty-four cases of gas phlegmon were fatal. Twenty-one were the result of accidents (nineteen complicated fractures, two lacerations of the soft parts). Gas phlegmon thus occurred in 3 per cent of the 700 cases of complicated fractures or more extensive lacerations of the soft parts in which treatment was given during the period from 1920 to 1936. All the accident patients were admitted within two and a half hours after the injury. In most cases the early symptoms of gas phlegmon appeared in from half a day to three days after the injury, in two cases in five and seven days respectively. The incubation period for the fatal cases was from one to seven days. Of the ten patients treated by amputation within six hours, nine recovered; of the nine in whom amputation was done after six hours of expectation, five recovered, and of the five treated conservatively, four recovered.

JOURNALS ABSTRACTED IN THE CURRENT MEDICAL LITERATURE DEPARTMENT, JANUARY-JUNE, 1938

Abstracts of important articles in the following journals have been made in the Current Literature Department of THE JOURNAL during the past six months. Any of the journals, except those starred, will be lent by THE JOURNAL to subscribers in continental United States and Canada and to members of the American Medical Association for a period not exceeding three days. Three journals may be borrowed at a time. No journals are available prior to 1928. Requests for periodicals should be addressed to the Library of the American Medical Association and should be accompanied by stamps to cover postage (6 cents if one and 18 cents if three periodicals are requested). Thus most of these journals are accessible to the general practitioner.

SUBJECT INDEX

This is an index to all the reading matter in THE JOURNAL. In the Current Medical Literature Department only the articles which have been abstracted are indexed.

The letters used to explain in which department the matter indexed appears are as follows: "BI," Bureau of Investigation; "E," Editorial; "C," Correspondence; "ab," abstracts; the star (*) indicates an original article in THE JOURNAL.

This is a subject index and one should, therefore, look for the subject word, with the following exceptions: "Book Notices," "Deaths," "Medicolegal Abstracts" and "Societies" are indexed under these titles at the end of the letters "B," "D," "M," and "S." State board examinations are entered under the general heading State Board Reports, and not under the names of the individual states. Matter pertaining to the Association is indexed under "American Medical Association." The name of the author, in brackets, follows the subject entry.

For author index see page 2240.

For index to Organization Section see page 243B.

A

A.T.10: See Dihydrotachysterol
 ABANDONMENT of Patients: See Medicolegal Abstracts at end of letter M
 ABDERRHALDEN'S REACTION, interferometric blood examination, [Zippert] 64—C
 ABDOMEN: See also Ascites
 acute, and mesenteric lymphadenitis, [Adams] 1519—ab
 acute conditions, when not to operate, [Aynesworth] 317—ab
 acute disorders, axillary and rectal temperatures in, 1296
 Adhesions: See Adhesions
 breath sounds over, in patient dying from hemorrhage, 1305
 diagnostic symptoms in functional vomiting, [Wilbur & Washburn] *479
 diagnostic symptoms of hyperactive carotid sinus reflex, [Stern] *1986
 Distension: See Flatulence
 gangrene (progressive postoperative) of wall, [Hiebert] 1316—ab
 pain from exercise, 1695
 pain in childhood, [Windorfer] 164—ab
 surgery, ileus and distention after, prostigmine for, [Harger & Wilkey] *1165
 surgery, patients not confined to bed after, 2021
 suture of wall with buried wires, [Dambrin] 162—ab
 tumor in wall from pine needle swallowed years before, [Smith & Priestley] *2067
 tumor, retroperitoneal hematoma with arteriosclerotic plaque perforation, [Frazier] *1437
 ABELL, IRVIN: See also Index to Organization Section
 to receive Laetare medal, 1117; (Governor Chandler praises physicians) 1115—E; (portrait) 1970; (president's address) *2041
 ABNORMALITIES: See Deformities; Uterus
 ABORTION, criminal (Mrs. Brandenburg sentenced) 447; (Frank Kish, janitor sentenced) 1117
 criminal (possible), as cause of death; medicolegal aspect, 147
 effect on declining birth rate, England, 908
 etiology: syphilis; nephritis, 596
 gonorrhea and, [Kushelevsky] 1411—ab
 habitual, preventive treatment, (vitamin E) [Currie] 772—ab; (injecting pregnancy serum) [Rosenfeld] 1790—ab; (vitamin E, progesterone, etc.) 1944; (progesterone) [Elden] 1954—ab
 induced (attempted), effect on fetus, 308
 induced by Ergoaploil, fatal cerebral damage in, [Lowenberg] *573
 induced by sea tangle tents, 1859
 intermenstrual discharge after, 1621
 legislation on notification, England (B.M.A. opposes) 220; (debate on) 1295
 statistics, Germany, 453
 syndicate, state board inspector (W. A. Byrne) convicted, 585
 ABSCESS: See also Carbuncle; Lungs; Mediastinum; Pilegmon; Thigh; Ulcer
 metastatic, after strain, 66
 ABSORPTION: See also Dextrose; Drugs; Mucous Membranes; Poisons; Skin; Ureters
 rate of fluids in proctoclysis? 67
 Test: See Blood groups; Semen
 ACACIA Treatment: See Ascites; Hemorrhage; Kidneys disease; Shock
 ACADEMY: See also American; Brooklyn; Cleveland; Harrisburg; New York; Rochester; etc.
 learned, of nazi students league, founded, 1057
 of Medicine, France, (Grégoire elected fellow) 298; (summary at end of articles obligatory) 522; (Bezançon elected president) 522; (Peyton Rous elected fellow) 909
 of Medicine of Toronto, 2018
 of Medicine, Rome, discussed treatment of rheumatism, 2168
 of surgery, Paris, (Chevassu elected president) 522

ACCIDENTS: See also National Safety; Trauma; Index to Organization Section
 Automobile: See Automobiles
 fatal, statistics, Germany, 753
 Fourth of July, campaign against, 2090; 2159
 in 1937, 818—E
 Industrial: See Industrial
 ACE bandage: See Knee injuries
 ACETARSONE Treatment: See Syphilis, congenital; Vaginitis
 ACETATES, nail polishes and lacquers, 1943
 ACETONE-methanol, industrial hazard, [Greenburg] 1403—ab
 ACETONEMIA: See Blood; Vomiting
 ACETONURIA: See Urine
 ACETOPHENETIDIN, acetylsalicylic acid and sodium salicylate, 460
 ACETYL-BETA-AMETHOLYL CHLORIDE: See Mecholy
 ACETYLCHOLINE, peptic ulcer formation, [Necheles] 537—ab
 ACETYL-SULFANILAMIDE, toxicity, [Marshall & others] *253
 ACHONDROPLASIA: See Chondrodysplasia
 ACID, acetylsalicylic, acetophenetidin and sodium salicylate, 460
 acetylsalicylic nostrum: Midol, 1945—BI
 acetylsalicylic, use in tuberculous patients who "streak" blood, 2104
 Amino Acids: See Amino Acids
 Aminoacetic: See also Adipos dolorosa
 Aminoacetic Acid-Mallinckrodt, 2155
 Aminoacetic Acid-Paul-Lewis, 129
 Cervitamic: See also Vitamins, C
 cervitamic, allowable claims (N. N. R.), [Fishbein] *578
 cervitamic, determination with dichlorophenolindophenol, [Rotter] 1411—ab
 cervitamic, diuretic action, [Stefanutti] 615—ab
 cervitamic, excretion in hematemesis and melena, [Lazarus] 318—ab; [Portnoy] 1877—ab
 Cervitamic, in Blood: See Blood, vitamin C
 Cervitamic, in Spinal Fluid: See Cerebrospinal Fluid, vitamin C
 Cervitamic, in Urine: See Urine, vitamin C
 cervitamic, intravenous test dose, [Wortis & others] *1896
 cervitamic, intravenously in diabetes, [Oshlma] 1797—ab
 cervitamic, metabolism in mother and nursing, [Neuweller] 2183—ab
 cervitamic, output in diet treatment of chronic arthritis, [Hare] 852—ab
 cervitamic, relation to complement, 2157—E
 cervitamic (synthetic), inadequacy, [Elmby] 613—ab
 cervitamic, Tablets Cervitamic Acid P. D. & Co., 1837
 cervitamic, to overcome intolerance to arsenphenamine and to diphtheria antiserum, 2021
 Cervitamic Treatment: See Addison's disease; Asthma; Paratyphoid
 cholalic, role in biliary lithiasis, [Chabrol] 403—ab
 Dehydrocholic: See Bile Ducts calculi
 dextrotrataric infections with paratyphoid B bacilli fermenting, [Kristensen] 542—ab; [Bojlen] 774—ab
 fatty, dehydrogenation power of leukemic leukocytes for, [Bossal] 163—ab
 Hippuric Test: See Liver function
 homogenistic, gives urine dark smoky color in ochronosis, [Seaborn] *576
 Hydrochloric: See Cerebrospinal Fluid tests; Kidneys function test; Stomach acidity
 paraHydroxybenzoic: See Acid salicylic
 iodoacetic, poisoning vs. riboflavin, and adrenal cortex extract, [Hogan] *1192
 Mandelic: See also Pyuria, treatment
 Mandelic Acid-Calco, 1837
 mandelic, behavior, 1502
 Nicotinic: See also Pellagra
 nicotinic, [McCay] *1444
 nitric (fuming), cauterizing dog bite with, 1945; 1946
 nucleic (yeast) and adenylic, action on heart muscle, 731
 salicylic and benzoic, compatible with calamine and phenol? 1390

ACID—Continued
 Salicylic (Mester's Test): See Arthritis, diagnosis
 salicylic, proprietary esters of parahydroxybenzoic acid, 919
 salicylic, with lard, skin absorption, [Seelman] 1127—C
 sulfuric, test for alcohol on breath, [Harger & others] *779
 Tannic: See also Rhinitis, allergic
 tannic, as preventive for colds and poliomyelitis, 530
 trichloroacetic, in pencil form for ophthalmic cauterization, 1775
 Uric: See Blood; Uric Acid
 ACIDOPHILUS Milk: See Colitis
 ACIDOSIS after sulfanilamide, [Marshall & others] *254
 in renal disease, [Stanojevich] 1965—ab
 ACNE, rosacea, treatment, 459
 ACRIDINE Derivative (Flaradine): See Gonorrhea, treatment
 ACRIFLAVINE Treatment: See Encephalitis, Epidemic; Gonorrhea; Meningitis, cerebrospinal
 ACRODYNIA, possible, 307
 ACTINOMYCOSIS, Actinomyces caprae infection, [Gibson] 1960—ab
 meningitis; primary focus in finger, [Morrison & others] *1552
 pulmonary, prognosis of roentgen therapy of, [Kuhlmann] 475—ab
 treatment, short wave, [Dieker] 1718—ab
 ADDICTION: See Alcoholism; Barbiturates; Cannabis Sativa; Morphine; Narcotics
 ADDISON'S ANEMIA: See Anemia, Pernicious
 ADDISON'S DISEASE, diagnosis, low salt diet in, [Lillienfeld] *804
 diagnosis from blood, [Riml] 2185—ab
 treatment, cervitamic acid, 1121
 ADENOCARCINOMA, in one cavity of biseptate uterus, [Shelley] *1913
 of kidney coexisting with other malignancies, [Eisenstaedt] *2056
 subsequent to nodular goiter of new-born [Stevens & Walte] *803
 ADENOMA: See Fibro-adenoma
 ADHESIONS, abdominal, and use of papain, [Donaldson] 691—ab
 ADIE'S SYNDROME often mistaken for neurosyphilis, [Kennedy] 538—ab
 ADIPOSIIS dolorosa (Dercum's disease); prostigmine and aminoacetic acid for asthenic phase, [Wohl & Pastor] *1261
 ADOLESCENCE, health of workers, Belgium, 2095
 obesity in; cured without injections, [Gray] *1430
 precocious puberty from estrogens in gonorrhea, 2026
 precocious puberty from Folluteln, [Thompson & Heckel] *1813
 pregnancy and labor in, [Nlcora] 1964—ab
 prepuberal intra-abdominal cryptorchidism, gonadotropic substance for, [Dorff] *1799
 puberty earlier in German youth, 1616
 ADRENALIN: See Epinephrine
 ADRENALS: See also Addison's Disease
 cortex extract and iodoacetic acid poisoning, [Hogan] *1192
 cortex extract treatment of enteric fever, [Najib-Farah] 2120—ab
 cortex extract treatment of hayfever, 1772
 cortical syndrome from tumor in child, 596
 diabetes mellitus and, 654—E
 dysfunction, relation to gastric ulcer, 908
 hemorrhage, Waterhouse-Friderichsen syndrome, [Kamber] 856—ab; [Craster & Simon] *1071
 roentgen rays effect on metastases, role in hypertension, tumor metastasizes, 827—ab
 ADSORPTION: See Virus

7-DEHYDRO-CHOLESTEROL, [Folberth] 1241—ab; [Bills] *2150
7-DEHYDRO-STROSTEROL, [Bills] *2150
DELIRIUM Tremens: See Alcoholism
DELOUSING: See Pediculosis
DEMENTIA PARALYTICA, juvenile, 919
malarial blood from patient for treating dementia praecox, 1512
seizures in, from hypoglycemia, [Birnbau] 470—ab
treatment, antipsychotic, after malaria, 60
treatment at Innsbruck Clinic, [Schmuttmayer] 1527—ab
DEMENTIA PRAECOX, blood circulation time, [Freeman] 1520—ab
central autonomic nervous system and, [Singer] *2048
Joan Nanu-Muscel prize for best work on, 224
oxygen metabolism defective in, [Hoskins] 315—ab
treatment, insulin shock, [Halpern] 213—ab;
[Cameron] 607—ab; [Katzenbogen] 690—ab; [Ziskind & others] 758—C; [Ziskind] 915—C; (action on central nervous system) [Gellhorn] *1433; 1819; [Krasnushkin] 1883—ab; [Freudenberg] 2119—ab
treatment, insulin shock combined with metrazol, [Erb] 701—ab; [Kasteln] 702—ab; [Querido] 940—ab
treatment, insulin shock vs. metrazol convulsions, [Friedman] 144—C; [Kennedy] 852—ab; [Strecker] 1714—ab; (electrocardiogram), [Hador] 1529—ab
treatment, malarial blood from dementia paralytica patient, 1512
treatment, malaria, electrolytically, vaccines and hot baths, [O'Leary] *42
treatment, metrazol convulsions, [Van Wulf-ton Pathle] 476—ab; [McAdoo] 524—C; [Pinkelman & others] *706; [Low] 1785—ab; 1819; [Keece] 2180—ab
treatment, protamine zinc insulin unsuitable for shock therapy, [Keece] 223—ab
DENTAL: See Teeth
Military Medico-dental Course: See Army, U.S.
Practice Acts: See Medicolegal Abstracts at end of letter M; Index to Organization Section
services (improved) for students, Germany, 2020
DENTISTS: See Index to Organization Section
DEODORANT, Yodora, dermatitis due to, [Grolnick] *951
DEPRESSION, MENTAL: See Mental Depression
DERCUM'S DISEASE: See Adiposis dolorosa

DERMATITIS: See also Eczema; Urticaria; etc.;
Medicolegal Abstracts at end of letter M
atopic, leukopenic index test in, [Rusten]
469—ab
Contact: See Dermatitis venenata
contagious pustular, of sheep ("Orf") in hu-
mans, [Peterkin] 242—ab
Drug: See Arsenic
Eczematoid: See also Eczema
eczematoid recurrent, of hands, 65
eczematosa from butesin pterate, [King] 771
—ab
from black clothing, 1693
from dress shields, 1772
from hemorrhoidal ointment, [Grolnick] *951
from invert sugar for varicose veins in-
jections, 1774
from shoe leather, [Niles] *363
from using dry shavers, [Shelton] *1748
herpetiformis, etiology, 677
herpetiformis, on soles of feet also on hands,
916
Radium: See Radium
rat antidermatitis factor (vitamin B₆),
[Fouts] 766—ab; [Sebrin] *1666
venenata and yeast dermatoses, [Ormsby]
1231—ab
vulvar, from condom, 389
DERMATOLOGISTS, German, Congress of, 452
DERMATOLOGY register at Army Medical
Museum, 1202
American Academy of, organized, 378
American Association, 1933
DERMATOMYCOSIS: See Mycosis
DERMATOSIS: See Skin disease
DESICCATION: See Rectum cancer
DEVICES, diagnostic and therapeutic, Wheeler-
Lea Bill, 1112—E; 1462; 1840—E
DEXTROSE, absorption from small intestine in
deficiency disease, [Groen] 1405—ab
In Spinal Fluid: See Cerebrospinal Fluid
injection (intravenous), concentration of solu-
tion for, danger of thrombosis? 307
injections (intravenous), nerve injuries from,
[Hassin] *948; [Nicoll] 1854—C; (reply)
[Hassin] 1854—C
injection (intravenous) or orally in damaged
liver (jaundice), [White] 1853—C
injection, solutions accepted for N. N. R.
(Abbott), 581; 2083; [McClure], 2155
Treatment: See Asthma; Eclampsia
DIABETES MELLITUS: See also Medicolegal
Abstracts at end of letter M
adrenals and, 654—E
blood pressure and, [Donohoff] 1632—ab
blood sugar in cells and plasma, [Larizza]
939—ab
blood sugar level and sugar utilization rate,
[Soskin] 238—ab
clinic (Renzelhausen) dedicated, 822
coma, extreme hyperglycemia, 1511
coma, unusual insulin and salt requirement,
[Root & Risenman] *1730
coma without glycosuria, 917
complications, gangrene of lower extremities,
[Dibold] 406—ab
complications, renal papillae necroses, [Gün-
ther] 84—ab
complications, tuberculosis (pulmonary), [Pi-
gerstorfer] 939—ab; [Ralli] 1787—ab
honey in, 598
in children, diet for, [Lichtenstein] 1523—ab
in children, growth retarded in, [Boyd] 1783
—ab
incidence, 652—E; *660
insulin in, 1129
insulin in, "delayed action," [Umbert] 1965
—ab
insulin in, Oralsulin, 1858

Medicolegal Abstracts—Continued

ASPHYXIATION: symptoms of death from coal

gas, 602

workmen's compensation in relation to, 602

AUTOPSIES: unauthorized; liability of physician for performing, 1782

BARBITAL: See Barbituric Acid Derivatives and Compounds

BARBITURIC ACID DERIVATIVES AND COMPOUNDS: barbitol; insurance, accident, in relation to death from, 1314

BELL'S PALSY: See Paralysis, facial

BEVERAGES: amebic dysentery; fly in soft drink as cause of disease, 1703

BIRTH: See Childbirth; Contraception

BIRTH CONTROL: See also Contraception

contraceptives; city's right to regulate distribution, 2110

BLOOD: paternity; blood-grouping test to determine, 466

CANCER: hypernephroma of kidney in relation to malignant tumor of lungs, 683

lung tumor in relation to hypernephroma of kidney, 683

metastasis; tumor of lungs as primary or metastatic, 683

CANNABIS: See Narcotics

CARBON MONOXIDE: death from: symptoms of, 602

CHILD BIRTH: prenatal injuries; liability for, 1703

CHIROPRACTIC: as practice of medicine, 925

cerebral hemorrhage and death following treatment, 683

"medical services," adjustments as constituting, 925

CLINICS: medical; income of physician guaranteed; validity of guarantee, 73

COMPENSATION OF PHYSICIANS: death of patient; effect on value of services, 1223

examining physician appointed at instance of defendant in personal injury suit, 1863

income guaranteed by agent of corporation; validity of guarantee, 73

reasonableness; death of patient as element, 1223

witnesses, expert; fees taxable as court costs, 236

workmen's compensation in relation to, 1398, 1805

CONTRACEPTION: pessaries imported by physician; when subject to seizure, 1518

CONTRACEPTIVES: See Birth Control

CONTRACTS: income of clinic physician guaranteed; authority of agent to bind principal, 73

limitations on medical practice; validity of agreements, 2032

telephone directory; failure to include physician's name in classified section, 1626

CORPORATIONS: optometry; right to practice, 926

DEMENTIA PARALYTICA: See Insanity in Civil Relations

DENTAL PRACTICE ACTS: advertising specialists; when announcement of specialty permissible, 925

advertising; statutory restrictions; validity of, 154, 535, 1951

group practice; advertisement of specialists, 925

DERMATITIS: workmen's compensation in relation to, 1517

DIABETES gangrene; trauma in relation to, 2109

sclerosis, coronary; death from in relation to trauma and diabetes, 396

workmen's compensation in relation to, 235

DISEASES: See also under particular diseases;

Workmen's Compensation Acts

hypertension as a disease, 1062

DRUGS: misbranding; advertising matter not accompanying drug as evidence, 1865

DYSENTERY: amebic; fly in soft drink as cause of, 1703

ELECTROLYSIS: practice of medicine in relation to, 839

EVIDENCE: See also Malpractice

books, medical; admissibility, 1625

complaints and statements; of persons examined for purposes other than treatment, 1398

demonstrative; defendant's right to physical examination of plaintiff who has exhibited injury to jury, 1139

hospital records; admissibility, 1951

hospital records; impeachment of medical witness, 1140

judicial notice; blood-grouping tests, 466

witnesses, expert; opinion testimony; basis of complaints and statements of persons examined for purposes other than treatment, 1398

FEDERAL FOOD AND DRUGS ACT: drugs; misbranding; advertising matter not accompanying drug as evidence, 1865

GONORRHEA: as disease of organ common to both sexes, 1625

insurance, health, in relation to, 1625

GROUP HEALTH ASSOCIATIONS: liability under bond to agency supplying service, 1866

HAIR: electrolysis; practice of medicine, 839

HARRISON NARCOTIC ACTS: indictment; sale

in and from original stamped package, 312

violation a felony and involves moral turpitude, 2032

HEAT PROSTRATION: insurance, accident, in relation to, 396

HEMORRHAGES: cerebral; arteriosclerosis and strain (over-exertion) in relation to, 926

cerebral; arteriosclerosis and trauma in relation to, 1397

cerebral; chiropractic treatment in relation to, 683

HERNIA: operation; psychosis in relation to, 236

workmen's compensation in relation to, 396, 601, 1313

HOSPITALS, IN GENERAL: associations

formed to supply service; liability to hospital rendering service, 1866

emergency care of indigents; liability of county, 465

fees; liability of county for hospitalization of indigents, 465

indigents; county's liability for cost of hospitalization, 465

medical services; duty of hospital to safeguard patients, 74

medical services; responsibility of hospital when physician not licensed, 74

nurses; liability for negligence of, 1140, 1782

records; admissibility in evidence, 1951

records; impeachment of medical witness, 1140

HYPERNEPHROMA: See Cancer

HYPERTENSION: as a disease, 1062

INDIGENTS: emergency hospital care; county's liability, 465

county's liability for hospitalization costs limited to funds available, 465

INJURIES: prenatal; liability for, 1703

INSANITY IN CIVIL RELATIONS: dementia paralytica; insurance, health; failure to give notice excused, 74

workmen's compensation in relation to, 765

INSURANCE, ACCIDENT: barbitol; death from, 1314

heat prostration, 396

roentgen burns sustained by dentist, 536

INSURANCE, HEALTH: gonorrhea; as disease of organ common to both sexes, 1625

hospital associations; liability under bond to hospital furnishing services, 1866

notice of disability; dementia paralytica excuses failure to give, 74

INSURANCE, INDEMNITY: malpractice; negligence occurring prior to date of policy, 1063

malpractice; evidence showing existence of insurance; admissibility, 1703

INSURANCE, LIFE: malignant tumor of lungs as primary or metastatic tumor, 683

LANDSTEINER TESTS: See Paternity

LUNGS: collapse of; strain in relation to, 1704

collapse of; workmen's compensation in relation to, 1704

MALPRACTICE: abandonment of patients, 1314

anesthetist; liability for negligence of surgeon, 684

bill of particulars; limitation of actions, 839

burns; glucose solution, 1063

burns; hot water bottle, 1782

burns; infra-red lamp, 1703

burns; res ipsa loquitur, 1703

cancer; injury to patient from administration of nostrum by layman, 74

chiropractors; cerebral hemorrhage and death following treatment, 683

chiropractors; osteomyelitis mistakenly diagnosed, 839

chiropractors; standard by which judged, 839

evidence; causal connection between injury and negligence; proof necessary, 1517

evidence; direct evidence unnecessary, 1314

evidence; indemnity insurance, 1703

evidence; res ipsa loquitur; infra-red lamp burn, 1703

evidence; witnesses, expert; nonsectarian physician may testify concerning sectarian practice, when, 683, 839

fistula, fecal, following operation for intestinal obstruction, 1314

foreign bodies; sponges, 684

fractures; nonunion attributed to rickets, 1781

fractures; spiral; failure to remanipulate after slipping of fragments, 312

glucose solution; burn sustained by patient, 1063

hemorrhage, cerebral; chiropractic treatment in relation to, 683

indemnity insurance; evidence of, admissibility, 1703

indemnity insurance; negligence occurring prior to date of policy, 1063

intestinal obstruction; fecal fistula following operation, 1314

limitation of actions; bill of particulars setting up new cause of action, 839

mastoidectomy; facial paralysis in relation to, 73

negligence; burden of proof on plaintiff, 684

nurses; exonerated from negligence; effect on physician's liability, 1703

MALPRACTICE—Continued

nurses; hospital's liability for negligence of, 1140, 1782

nurses; special; physician's liability for negligence of, 1063

paralysis, facial; mastoidectomy in relation to, 73

roentgenograms; necessity for, 1865

skill and care; standards; by which sectarian practitioners judged, 839

sponges; accidentally left in patients, 684

tortfeasors; release of as affecting physician's liability, 235, 1866

vertebra; dislocation of; failure to reduce, 1517

workmen's compensation acts; jurisdiction of commission exclusive, 74

MARIHUANA: See Narcotics, cannabis

MESSAGE: as "medical services," 2110

MASTOIDITIS: facial paralysis attributed to operation, 73

MEDICAL PRACTICE ACTS: blood pressure tests as practice of medicine, 1062

chiropractic as practice of medicine, 925

diagnosis; blood pressure tests in relation to, 1062

"doctor;" use of title by drugless healer, 765

drugless healers; use of title "doctor," 765

electrolysis; removal of superfluous hair, 839

enforcement; information; charges stated disjunctively, 1952

enforcement; injunction to restrain violations, 312

exemptions; faith healers, 1703

faith healers; exemption from act, 1703

hypertension as a disease, 1062

licenses; prior practice as qualification for, 154

licenses; revocation; cause for, in general; board may not prescribe, 765

licenses; revocation; "doctor;" use of title by drugless healer, 765

licenses; revocation; felony, conviction of, 2032

licenses; revocation; Harrison Narcotic Act; violation a felony and involves moral turpitude, 2032

licenses; revocation; moral turpitude; violation of Harrison Narcotic Act, 2032

nuisances; unlicensed practice of medicine as constituting, 312

MEDICAL SERVICES: chiropractic adjustments as constituting, 925

massage as constituting, 2110

METASTASIS: See Cancer

NARCOTICS: cannabis; possession of growing plant illegal, 1140

cannabis; sufficiency of information charging sale of cigarettes, 1952

NUISANCES: medical practice acts; violations as constituting, 312

NURSES: hospital; liability for negligence of, 1140, 1782

special; physician's liability for negligence of, 1063

OPTOMETRY PRACTICE ACTS: advertising; statutory restrictions valid, 154

corporations; right to practice optometry, 926

employment of licensee by unlicensed non-resident prohibited, 154

porphyria after, [Rimington] 2120—ab
sale over the counter, protest against, France, 1501
toxicity, [Marshall & others] *252
toxicity? agranulocytosis (fatal) from, [Schwartzman & others] *368; [Berg & Holtzman] *370; 372—E
toxicity; cyanosis from, 1683; [King & others] *2069
toxicity; rash, [Malnzer] 1233—ab
treatment after transurethral prostatectomy, [Gaudin & others] *1887
treatment, blood cell response to, [Bigler] 1785—ab
treatment, evaluated, 1378
treatment in ophthalmology, [Goldenberg] 928—ab
treatment, leukocyte response to, [Bigler & others] *343; 372—E
treatment of chancre, [Hanschell] 2121—ab
treatment of endocarditis, [Muether] 603—ab
treatment of erysipelas, [Snodgrass] 612—ab
treatment of gonococcal meningitis, [Marrin & Wilkinson] *800
treatment of gonococcal rheumatism, [Brulé] 698—ab
treatment of gonococcal urethritis, [Farrell & others] *1176
treatment of gonorrhea, 51—E; [Felke] 1151—ab; 1879; 1501; [Brunet] 1710—ab
treatment of gonorrheal vulvovaginitis, [Hoffman & others] *1541
treatment of hemolytic streptococcal (group C) infections, [Seastone] 240—ab
treatment of hemolytic streptococcus meningitis, [Smith & others] *887; [Silverthorne] 1958—ab
treatment of Ludwig's angina, [Fulghum] 850—ab
treatment of meningococcal meningitis, [Willien] *630; (intrathecal) [Eldahl] 2037—ab
treatment of ophthalmia neonatorum, [Willis] 933—ab
treatment of pemphigus, [Caro] 1064—ab
treatment of puerperal fever, [Colebrook] 540—ab
treatment of pyelitis, [Villani] 611—ab
treatment of pyelonephritis with nephrocalcinosis, [Albright & others] *357
treatment of rheumatic fever, [Swift & others] *426
treatment of septic patient with otitis media, [Maxwell] *1536
treatment of staphylococcus meningitis in young infant, [Bloch & Pacella] *508
treatment of streptococcal infections, [Kolmer] 159—ab; [Smith] 242—ab; [Ballon] 608—ab; [Flake] 694—ab
treatment of undulant fever, [Stern & Blake] *1550; [Toone] 2117—ab
treatment (protective) of influenza infections, [Chumke & others] 2099—C
- SULFATE** ions beneficial effect in chronic nephritis, [Barker] 841—ab; (correction) 1202
- SULFODIOXYGENIA** or arthrox, 1385—BI
- SULFONIL** of William P. Poythress & Co., Inc., 461
- SULFONE:** See under Sulfanilamide and Derivatives
- SULFOPHOSPHOVANILIN** Reaction: See Blood lipoids
- SULFUR:** See also Acid, sulfuric
administered orally, [Kühn] 1882—ab
containing amino acid; cystine and methionine, 1196—E
Hyposols Sulfocol, 814
metabolism in children with typhoid, [Biddau] 1881—ab
Soap Paste: See Scabies, treatment
SULISOCOL, Hyposols Sulfocol, 814
SUMMER round-up of children, 442—E
SUMMIT Mineral Spring Water, 958
- SUN:** See also Sunlight
Bath: See Tuberculosis, treatment
lamp, Sperti, 1925
- SUNBURN** treatment, Nupercalnal—"Cliba" 441
- SUNLIGHT** as factor in pellagra, [Sebrell] *1669
deprivation, cause of war dropsy and prison edema, [Mann] 693—ab
failure to protect against rickets, [Moore] 397—ab
- SUNNY** Dell Brand Evaporated Milk, 1837
- SUNRAYS** Wheat Selex, 958
- SUPPOSITORIES:** See Mercurin; Merthiolate

T

- T factor in sesame oil, effect on number of thrombocytes, [Schiff] 244—ab
TABES DORSALIS, gastric crises, 1692
herpes zoster in, 67
hysterectomy contraindicated in? 2104
treatment, malarial, electropexia, vaccines and hot baths, [O'Leary] *42
TACHYSTEROLOL: See also DihydrotachysteroLOL [Bills] *2151
TAIANA, J. A., honored, 1849
TAKATA TEST: See also Liver Disorders; Malaria, therapeutic; Tuberculosis, surgical blood proteins in, [Gros] 406—ab
review of, 700, 1685
Takata-Ara test, [Snell & Magath] *172
Takata-Dohmoto flocculation test in pregnancy, also to determine ovulation time, [Charamis] 475—ab
TALKING: See Speech; Voice
TAMINI, LUIS, death, 1849
TAMPONS: regular sanitation, *790
TAN: iment, tetra-
TAF: 16—ab
TAPEWORMS, human and dog, terminology of, 1696
in fish from Washington state; effect of kippers and smoking, 2028
TAPIOCA, sensitivity to, 149
TARRANT County Medical Society (Texas) graduate courses for physicians in 1906, 1610—E
TATTOO, gentian violet, [Sutton] *1733
marks, removal, 2100
TAX: See also Cannabis Sativa; Index to Organization Section
income, and social security, 1464
system (complicated) for French physicians, 381, 1763
TEA, Therapeutic Use: See Burns
TEACHERS, doctors and parents, 442—E
tuberculosis in, 58
vaccination, 1052
TEACHING: See Education, Medical
TEARS, bloody; bilateral capillary hemangiomas [Dimity] *643; (reply: due to occlusion of posterior inferior cerebellar artery) [Zierler] 1387—C
TECHNICAL Subcommittee on Medical Care: See also Index to Organization Section
National Health Program, 652—E; *656
TECHNICIANS: See Laboratory; Physical Therapy
TEETH: See also Dental; Gums; Jaws; etc.
bacteriology (postmortem), [Burn] 2112—ab
calcium metabolism and, [Schour] *870
Calcium formed around: See Gums
eruption factor in determining age, 3510
eruption; relation to intelligence, 1659
infection, diagnosis by short wave provocation, [Gutzeit] 1529—ab
nerve terminations in, [Tiers] 1620—ab
removal, for pyorrhea, 1855
resorption after orthodontic treatment, 148
store teeth and store food, 1039—ab
vitamin A deficiency, [Beery & Wollbach] *2673
TELEPHONES: See Medical Legal Abstracts at end of letter M

TEMPERATURE, extremities in energy exchange and, [Sheard] 687—ab
Low: See Cold
TEMPERATURE BODY: See also Skin
axillary and rectal, in acute abdominal disorders, 1206
High: See Fever
low, in infants refusing to nurse, [Rademacher] 1242—ab
seasonal variation in tuberculosis, [Clayson] 161—ab
TENDON, flexor carpi ulnaris, calcification about, [Milch] 1786—ab
suture, 66
transplant for slipping patella, [Hauser] 1148—ab
transplant in paralytic foot deformities, 382
TENDONPLASTIC Amputation: See Amputation
TERMINOLOGY: See also "Words and Phrases"
under *Medicolegal Abstracts* at end of letter M
chondrodysplasia, [Gäde] 2125—ab
definitions of sound, noise, intensity, loudness and decible scale, [McCord & others] *1553
of medical institutions and offices, Italy, 1617
prematurity defined, 2164
psychosis and psychoneurosis defined, [Singer] *2049
STANDARD CLASSIFIED NOMENCLATURE OF DISEASE: explanation of code system, *509; (A. M. A. report) 1452; 1490
vitamin B glossary, [Nelsson] *647; *649; [Dann] 1620—C
TEST meal, time required for passage through gastro-intestinal tract, 2027
TESTIS, cancer, management, [Hinman & Powell] *188
changes after ligating deferent duct, [John] 141—ab
torsion of hydatid of Morgagni, 824
tumor (malignant), prognosis in, [Payne] 1714—ab
tumor, management, [Hinman & Powell] *188
undescended, gonadotropic principle for, 288—E; [Bigler] 1225—ab; [Dorr] *1799
TESTOSTERONE: See Androgens
TETANUS, antiserum, liver "atrophy" after injection, 1501
carriers, pigeons as, [Russell] 772—ab
cause of eleven deaths from cancer treatment, *1183; 1194—E; 1288—E
Gas Gangrene Antitoxin Concentrated and Refined, 129
treatment, alcohol intravenously for, 452; (plus serotherapy) [Merle] 698—ab
treatment, antitoxin (3,600,000 units), [Cables] *1271; [Vener] 2024—C
vaccination against, 451
TETANY, after using sodium bicarbonate, [Litchford] 1870—ab
hypoparathyroid, dihydrotachysterol (A. T.-10) for, [MacBryde] 767—ab
in early infancy, [Baar] 856—ab
magnesium, [Greenberg] 1628—ab
TETRACHLOROETHYLENE, experience with, [Maplewood] 686—ab
TETRA-ETHYL Lead: See Lead
TEXAS Surgical Society, 2017
THALASSOTHERAPY, International Association of, 1377
THEELIN: See Estrogens
THERAPYLINE Treatment: See Dyspnea
THERAPEUTICS: See also Fever, therapeutic; Hemotherapy; Physical Therapy; Röntgenotherapy; Serotherapy (cross reference); etc.; Index to Organization Section
Devices: See Devices
"dose-price" index and "efficiency price" index of various drugs, [Fantus] *880
therapy of Cook County Hospital, [Fantus] (hemostylis by Tice), *579; (jaundice by Steigmann), *732; (golter and hyperthyroidism by Seed), *1916
THERMOMETER in esophagus, [Schwartz] *953
THERMO-RAY Portable Short Wave Generator, 1673
THIAMIN CHLORIDE: See also Vitamins, B.
allowable claims (N. N. R.), [Fishbein] *578
carbohydrate metabolism and, [Gottlieb] 1883—ab
chemistry, [Williams] *727
effect on peripheral neuritis of pellagra, [Spies & Aring] *1081; 1115—E
excretion by pregnant and non-pregnant women, [Westenbrink] 1720—ab
in urine as index of nutrition level, [Harris] 1878—ab
Islands of Langerhans modified by, [Mosonyi] 1797—ab
research, Gibbs medal to R. R. Williams for, 747
treatment, intraspinal (for intractable pain), [Stern] 1705—ab; (for multiple sclerosis), 1859
treatment of alcoholic psychoses, [Brodsky] 2113—ab
treatment of neuritis, [Stevenson] 1715—ab
treatment of polyneuritis and cardiovascular conditions, [Strauss] *933; (advise caution), [Nara] 1387—C
treatment (preventive) of irradiation sickness, [Martin] 1790—ab
THIGH: See also Hip Joint
abscess (metastatic) after strain, 66
meralgia paraesthetica, [Ecker & Woltman] *1650

THIOSULFATE: See Sodium thiosulfate
THOMPSON rescope, [Emmett] *1809

THOMSON, R. B., death, 2167
THORACOPLASTY: See Tuberculosis, Pulmonary
THORAX: See also Pneumothorax
American Association for Thoracic Surgery, 1054
development in fetus, [Jonata] 541—ab
pain in chest, diagnosis, 529
THORIUM DIOXIDE: See also Breast roentgen study
colloidal, tissues after injecting, [Yater] 1225—ab
THRESHING fever or wheat miller's asthma, 1696
THROAT: See also Larynx; Neck; Tonsils
carrier of puerperal infection, [Durie] 1714—ab
normal, hemolytic streptococci from, [Frisch] 1145—ab
pains in, [von Ottingen] 1882—ab
sore (streptococci) outbreak (New York), 1118; 1679
sore (ulceronecrotic) in scarlet fever, [Anghelesco] 2122—ab
THROMBO-ANGIITIS OBLITERANS, complications, lipemia and xanthomatosis, [Barker] 686—ab
in sisters; oscilometry, [Wilensky & Collens] *1745
spasms of legs at night sign of? 2103
treatment, intermittent venous occlusion in, [Collens & Wilensky] (correction), 528—C
THROMBOCYTES; **THROMBOPENIA**: See Blood platelets; Purpura Haemorrhagica
THROMBOPHLEBITIS, appendical, complicating appendicitis cause of high mortality, 816—E; [Hawkes] 850—ab
THROMBOSIS: See also Embolism; Thrombophlebitis
auto-agglutination and, [Weiss] 476—ab
can thrombus be dissolved? 598
cerebellar artery (Wallenberg's syndrome), heparin for, [Magnusson] 1962—ab
coronary, and cerebral embolism, 1621
coronary, capillary rupture with hemorrhage in, [Paterson] 1956—ab
coronary, cause of death in, [Eppinger] 770—ab
coronary, electrocardiographic and postmortem study, [Smith] 604—ab
coronary, heart block in, [Kerr] 242—ab
coronary, in industrial workers, [Crain & Missal] *3
coronary, no relation to wearing garters, 2028
coronary occlusion, residual signs a year later, 759
coronary, postoperative, [Master & others] *1415
coronary, without pain, [Boyd] 313—ab
danger in using concentrated dextrose solution intravenously, 307
heparin and, [Murray & Best] *118; [Holmin] 1961—ab; [Magnusson] 1962—ab
in extremities, [de Takáts] *1078; *1079
peripheral, sign of visceral cancer? 1499
sinus (dural) in early life, [Bailey] 847—ab
sinus (lateral), [Irish] 1785—ab
sinus (lateral), differentiating from endocarditis, [Rosenwasser] 397—ab
treatment, Friedländer's compression bandages plus exercises, 142
venous (axillary) from strain or trauma, [Kaplan] *2059
venous (peripheral) sign of visceral cancer, 1449
venous (retinal), heparin for, [Holmin] 1961—ab
THYMOL Treatment: See Moniliasis
THYMOPHYSIN, Council decision, 390
THYMUS-pituitary mixtures in obstetrics, 390
THYROID: See also Golter; Golter, Exophthalmic
cancer, [Hare & Swinton] *327
cancer, 7 years after nodular goiter in newborn, [Stevens & Walte] *803
desiccated, dosage, 759
effect on blood pressure, [Kountz] 685—ab
Excision: See Thyroidectomy
extracts reduce cholesterol ester, [Fenz] 701
function and iodine tolerance, [Watson] 2035—ab
graft in infantile myxedema, [Le Fort] 404—ab
hemorrhage and cyst, 68
Hyperthyroidism: See Hyperthyroidism
Hypothyroidism: See Hypothyroidism
in arteriosclerosis, [Handorsky] 1964—ab
nodules, in necropsis in nonproliferous region, [Schlesinger & others] *1638
roentgen irradiation for heart diseases, [Galli] 1150—ab
THYROIDECTOMY, dangers of air embolism, [Guthrie] 541—ab
technic, choice of, 521
THYROIDITIS, chronic nonspecific, 48—E
THYROTROPIC Hormone: See Pituitary
THYRONINE controls growth of implanted tumors, [Moppett] 852—ab
THYTUITARY of the Blue Line Chemical Co., 390

TICKS, transmit Rocky Mountain spotted fever, [Parker] *1185; *1273; (prevention of bites), 1951
TINNITUS AURIUM, 2101
TISSUE: See also Epithelium; Reticulo-Endothelium; Skin; etc.
after colloidal thorium dioxide injection, [Yater] 1225—ab
Culture Virus: See Rabies
damaged, metabolism of, 2093
deformities, multiple appearance, [Holmqvist] 2186—ab
dissolving from skeleton, 759
heating by short wave diathermy, [Coulter & Osborne] *639
Lymphoid: See Lymphoid Tissue
reaction (hyperergic): temporary pulmonary infiltrates, [Busche] 1240—ab
TITANIUM oxalate: See Arteriosclerosis
TOBACCO-alcohol amblyopia, diet therapy, [Carroll] 469—ab
circulatory effects, [Thienes] 1953—ab
lead poisoning in cigar makers, 1123
mentholated cigarettes not responsible for cardiac deaths, 920
smoke inhalation, electrocardiographic changes from, [Graybiel] 927—ab
smoking, effects on vascular system, [Chapman] 80—ab
smoking, harmful properties of cigaret paper, [Wensch] 1410—ab
smoking in cardiovascular diseases, [Minnhaar] 83—ab
smoking, thrombo-angiitis obliterans in sisters, [Wilensky & Collens] *1745
TOBIAS, JOSE, honored, 1849
TODD, WINGATE, 25th anniversary, 135
TOES, ganglion (tumor) of, 1774
TOLEDO Academy of Medicine, new executive secretary, 1376
TOMATO Juice, Dale Brand, 958
vitamin C, Council report on, 650
TOMOGRAPHY: See Roentgen Rays
TONGUE, burning (with hot food) 307; (cause; treatment) 1858
TONSILLECTOMY, blood coagulation in, seasonal variation, [Rosenfeld] 690—ab
epidemics in schools vs., 1682
in rheumatism, 522; [Stetter] 617—ab; [Turnley] 689—ab; [Ash] 769—ab
TONSILLITIS: See Tonsils, infected
TONSILS, enlarged, in children aged 7-15 who were prematurely born, 1685
Excision: See Tonsillectomy
infected, hospital treatment recommended, 1766
lesions, relation to prostatitis, [Haven] 1404—ab
tuberculosis (primary) [Schlittler] 773—ab; [Libin] 1154—ab
TOOMEY'S hypothesis in whooping cough, 1927—E
TOOTH: See Teeth
TORTICOLLIS, spasmodic, reducing motor fibers for, [Masson] 606—ab
TOTTENHAM, ELIZABETH M., end mattress, 683
TOXEMIA, alimentary; autointoxication, 460
of Pregnancy: See Pregnancy
TOXICOLOGY: See Poisoning
TOXIN: See Diphtheria; Scarlet Fever
TOXISTROL, [Bills] *2151
TOXOID: See Staphylococcus
TRACHEA, artificial respiration by intratracheal insufflation (Meltzer), [Flagg] 304—C; [Henderson] 304—C
expanding airway tube, [Gwathmey] *892
obstruction (postoperative), helium to relieve, [Eversoll] *878
resuscitation of newborn, [Coburn] 831—C
TRACHEOBRONCHIAL SYSTEM, posture and drainage of, [Vinson] 2118—ab
TRACHEOBRONCHITIS, tuberculous, [Warren] 1628—ab
TRACHOMA in Western Queensland, 1766
TRACTION: See Amputation stumps; Jaws; Sacro-Iliac Joint strain
TRADE UNION Congress—B. M. A. committee report on rehabilitation of injured, 450
Oregon State Medical Society council opposes, 667
TRAINS: See Railroad
TRANSFUSION: See Blood Transfusion
TRANSPLANTATION: See Grafts (cross reference); Parathyroids; Pituitary; Tendon; etc.
TRAUMA: See also Accidents; Face; Head; Kidneys; Meningitis; Medicolegal Abstracts at end of letter M; Index to Organization Section
appendicitis for? 1926—E; 1943
in aged, psychosis, hematemeses and death, 917
in pulmonary tuberculosis, [Skolnick] 1234—ab
muscular atrophy and, [Sutton] 1318—ab
muscular dystrophy relation to, 1772
nasal polyps after, 306
osteomyelitis and osteoporosis develop 3 days after? 1390
paralysis (Landry's) and, 835
rehabilitation of injured; B. M. A.—Trade Union Congress committee, 450
thrombosis of axillary vein after, [Kaplan] *2059

TREADWAY, WALTER L., placed in charge of narcotic farm, 2018

TRENCH epilepsy cure fraud, 1853—BI

TREPHEINE: See Bone Marrow; Cranium

TRIBOULET Reaction: See Intestines disease

TRICHINOSIS, 584—E
diagnosis, Bachman intradermal and precipitin tests, 1854
epidemic, (Wisconsin) 519; (64 cases) [Ferenbaugh & others] *1434; (Iowa) 2014
postmortem study, [Schapf] 1937—ab
prevalence, [Schiefel] 1627—ab
subclinical, in Britain, [van Someren] 612—ab

TRICHLOROETHYLENE: See triChloroethylene

TRICHOMONAS vaginalis, diagnosis (cultural method vs. direct examination of wet preparations), [Magath] 1954—ab
vaginalis, stains for: carbolfuchsin, Ruhland, etc., 1692
vaginalis vaginitis, acetarsone (Devegan) for, [Cornell] 1317—ab

TRI-STATE Medical Association, 823

TROMBIDIOSIS, [Aretz] 1152—ab

TROMBONE player, herpes simplex in, 1509

TROPICAL disease, is there a tropical syphilis? [Bottema] 165—ab
medicine, (school at U. of Porto Rico) 749; (third International Congress) 1055
Ulcer: See Ulcer

TROPICS, hyperperistalsis and borborygmus in, 65
use of both salt and calcium in, 2104

TRYANOSOMA rhodesiense strain, infectivity of man to, [Corson] 161—ab
trypanocidal substances (undecane diamidine), [Kling] 613—ab

TRYPTOPHAN Reaction: See Cerebrospinal Fluid; Meningitis, tuberculous

TUBE FEEDING in paralysis of muscles of deglutition, liquid diet for, [Foley] 467—ab
sodium amygdal as substitute, [Foley] 467—ab

TUBERCLE BACILLUS, bacilluria, hemogram and bacilluria in, [Corlitzer] 542—ab
bovine, and tuberculous meningitis in children, [Lesné] 1716—ab
homogenization in sputum, [D'Arlenzo] 1320—ab
in gastric juice, [Lopez Bonilla] 616—ab; [Monaco] 1631—ab

TUBERCULIN, allergy in lymphatic gland diseases, [Rotta] 937—ab
